Amic acid $C_6H_5Me(SO_2NH_2)(CO_2H)_2$. A product of oxidation of mesitylene sulphonic amide with $KMnO_4$ (Hall a. Remsen, Am. 2, 136; Jacobsen). When set free from its salts it changes at once into the anhydride $C_6H_5NSO_3$ [270°], S. 5 at 100°.—KHA'' aq.—BaA'' aq.—BaA'' 8 aq.

SULPHO-ISOVALERIC ACID $C_5H_9SO_3$, *i.e.* $C_4H_8(SO_3H)CO_2H$. Formed by heating isovaleric acid (1 pt.) with $ClSO_3H$ (1 pt.) at 150° (De Varda, *G. 18*, 91). Deliquescent crystalline mass. Its aqueous solution partially decomposes when heated.— BaA'' aq.— PbA'' 2aq.

SULPHOXIDES. Organic compounds $R.SO.R'$ formed by the action of conc. HNO_3 on sulphides. Decomposed by heat. Reduced by Zn and H_2SO_4 and by HI to sulphides. Attacked by PCl_5 , sulphides being formed. They reduce $KMnO_4$, being converted into sulphones. Sulphoxides containing monovalent alcohol radicles form unstable compounds with HNO_3 , such as Et_2SO, HNO_3 (Beckmann, *J. pr.* [2] 17, 475).

SULPHO-XYLENE CARBOXYLIC ACID. *Amic acid* $C_6H_4Me_2(SO_2NH_2)CO_2H$ [1:3:4:5]. [268° cor.]. Formed by oxidising *p*-cumene sulphonie amide (Jacobsen a. Meyer, *B.* 16, 190). Long needles, sl. sol. hot water.— KA' aq.— BaA'' 2aq.

SULPHUR. S. At. w. 31.98. Mol. w. 63.96; probably also 191.88 and 255.84 (*v. infra*). *The following data apply to ordinary rhombic S.* Melts at $c. 115^\circ$; different observers give from 111° to 115° (*v. Helft*, *Z. P. C.* 12, 219; Spring, *A. Ch.* [5] 22, 170; Kopp, *A.* 93, 129; Brodie, *J. pr.* 62, 336; Gernez, *C. R.* 83, 217; for m.p. at high pressures *v. Hopkins*, *J.* 1854. 48). Boils at 440° (Dumas, *A. Ch.* [2] 36, 83; Troost a. Hautefeuille, *C. R.* 76, 76, 219). Calender a. Griffiths (*T.* 182, 119) give 444.53° as 'within 1° of the true temperature of the vapour of sulphur boiling freely under a pressure of 760 mm.' (This determination was made with Pt resistance thermometers with great care, but unfortunately no special precautions were taken to insure the purity of the S used. For other determinations *v. Carnelley's Melting- and Boiling-point Tables*, 1, 11. For b.p. under different pressures from 1 to 760 mm. *v. Monckman*, *Pr.* 46, 136.) S.G. *c.* 2.03 (for numerous data *v. Clarke's Table of Specific Gravities*, 2nd ed., 9). S.G. molten S 1.801 to 1.815 (Playfair a. Joule, *C. S. Mem.* 3, 76); S.G. at b.p. 1.46 to 1.51 (Ramsay, *C. J.* 35, 471). V.D. varies from *c.* 122 to *c.* 62; *v. infra*, *Molecular Weight of S.* S.H. (17° – 45°) $\cdot 163$ (Kopp, *T.* 1865. 71); (0° – 100°) $\cdot 1776$ (Bunsen, *P.* 141, 1). S.H. (liquid) $\cdot 2346$ (Person, *A. Ch.* [3] 21, 295). Latent heat of fusion = 9.368 (for 1 g. S) (Person, *L.c.*). S.V.S. 15.9. S.V. of S in combination varies from 28.6 to 22.6; S.V. at b.p. 21.6 (Ramsay, *C. J.* 35, 471). C.E. (linear) $\cdot 00006418$ (at 40°) (Fizeau, *C. R.* 68, 1125; *v. also* Kopp, *A.* 93, 129; Pisati, *G.* 1874. 29; Spring, *J.* 1881. 1085; Moitessier, *J.* 1866. 27, who gives C.E. for each *c.* 20° from 110° to 440°). S in CS_2 ; 16.54 at -11° , 18.75 at -6° , 23.99 at 0° , 37.15 at $+15^\circ$, 41.65 at 18.5° , 46.05 at 22° , 94.57 at 88° , 146.91 at 48.5° , 181.34 at 55° (Cossa, *B.* 1, 138; Payen, *C. R.* 84, 456, 508). For S.G. of solutions in CS_2 *v. Macagno* (*C. N.* 43, 192). For S. in C_2H_6 and other solvents *v. Pelouze* (*C. R.* 68, 1179; 79,

56). Refraction-equivalent ($\frac{\mu-1}{d}$, at.w.) for

D line 16.0 (solid), 16.47 (liquid), 16.1 (gaseous, for C line), 16.0 (in solution), 16.0 (calculated from data for SO_2), 16.1 (from data for S_2O_2)

(Gladstone, *P. M.* [5] 35, 204). H.C. $[S, O] = 71.080$ (*Th.* 2, 247). The E.C. of S is very small; it varies much with temperature (*v. Monckman*, *Pr.* 46, 136). The fundamental form of rhombic S is a simple pyramid, or elongated octahedron; *a:b:c* = $8106:1:1.898$. For emission-spectrum *v. Salet*, *C. R.* 68, 401; 73, 559; *Bl.* [2] 11, 302; Mulder, *J. pr.* 91, 112; Barrett, *J.* 1865. 138; Seguin, *C. R.* 53, 1272; Chautard, *C. R.* 79, 1123; Plücker a. Hittorf, *J.* 1863. 109. For absorption-spectrum of S vapour *v. Salet*, *C. R.* 74, 865; Gernez, *C. R.* 74, 803; Ciamician, *W. A. B.* 77 [2] 839. For vapour-pressures of S vapour *v. Regnault* (*J.* 1863. 65). Ignition point *c.* 250° (Hill, *C. N.* 61, 125; Blount, *C. N.* 61, 153).

The following data apply to monoclinic S. Melts at 117.4° (Gernez, *C. R.* 83, 217); at 120° (Brodie, *J. pr.* 62, 336). S.G. 1.982 (Marchand a. Scheerer, *J. pr.* 24, 129); 1.958 (Deville, *J.* 1, 365). S.V.S. 16.4 . H.C. $[S, O] = 71.720$ (*Th.* 2, 247; Petersen, *Z. P. C.* 8, 601). For volumes occupied at different temperatures *v. Toepler* (*W.* 47, 169). Crystallises in secondary forms of a monoclinic prism; *a:b:c* = $1.004:1:1.004$, angle *b:c* = $84^\circ 14'$. Sol. CS_2 , from which solution rhombic S crystallises out.

Insoluble sulphur is amorphous; insol. CS_2 ; S.G. *c.* 2.04 (Troost a. Hautefeuille, *C. R.* 69, 248); S.G. after compression at 8,000 atmos. 1.9556 at 0° , 1.9643 at 100° (Spring, *Bl. Acad. Belg.* [3] 2, 83).

Cf. Allotropy of Sulphur (p. 609).

Occurrence.—Native, in beds, in Sicily, Mexico, New Zealand, &c.; in the lava fissures of volcanic districts; in small quantities in the mud from the sea-bottom (Buchanan, *Pr. E.* 1891. 1). Many metallic sulphides also occur native—*e.g.* sulphides of Sb, As, Cu, Fe, Pb, Hg, and Zn. Sulphates occur in large quantities—*e.g.* gypsum, celestine, heavy spar; these and other sulphates are found in the earth's crust, in the sea, and in many river and spring waters. (For more details *v. DICTIONARY OF APPLIED CHEMISTRY*, iii. 682.) S is a constituent of albumen, hair, feathers, horn, and some other parts of animals; it is also found in many plants. Small quantities of S compounds are found in the atmosphere near volcanoes. According to Young sulphur occurs in the solar atmosphere (*Am. S.* [3] 4, 356).

Sulphur has been known from very early times. The quantitative work of Lavoisier, in 1772, on burning S showed this substance to be an element, but it was not finally placed on the list of elements until after the experiments of Gay-Lussac and Thénard in 1809.

Formation.—1. By the interaction of SO_2 and H_2S ; $2SO_2 + 4H_2S = 3S_2 + 4H_2O$.—2. By the partial oxidation of H_2S , either by incomplete combustion or by exposure of H_2SAq to a limited quantity of air; $2H_2S + O_2 = 2H_2O + S_2$. Also by the oxidation of FeS by exposure to moist air; $2FeS + 3O = Fe_2O_3 + S_2$.—3. By distilling certain metallic sulphides out of contact with air, *e.g.* $3FeS_2 = Fe_3S_4 + S_2$.—4. By decomposing solution of an alkali or alkaline polysulphide by acid; *e.g.* $CaS_2Aq + 2HClAq = CaCl_2Aq + H_2S = 2S_2$. Also by adding acid to solution of a thiosulphate; *e.g.* $Na_2S_2O_3Aq + 2HClAq = 2NaClAq + H_2O + SO_2Aq + S$.—5. By decom-

posing S_2Cl_2 by water ($2S_2Cl_2 + 2H_2O + Aq = 4HClAq + SO_2 + 3S$).—6. When sulphates, e.g. $CaSO_4$, are in prolonged contact with decaying organic matter (such as plant-leaves) they are reduced to sulphides, and if these come into contact with acids S is among the products of the reactions that occur. For a fuller account of some of these processes, whereby native S is probably formed, v. DICTIONARY OF APPLIED CHEMISTRY, iii. 683. For methods of forming the various varieties of S v. *infra*, Preparation.

Preparation.—1. Ordinary S is dissolved in pure, dry CS_2 ; a part of the CS_2 is distilled off, and the rest is allowed to deposit crystals of S. This process is repeated once or twice; the S crystals are powdered, kept *in vacuo* for some days to remove all CS_2 , and then repeatedly distilled *in vacuo*, the middle portion of the distillate being collected each time.—2. Ppd. S is distilled several times in S_2Cl_2 to remove H compounds; the distillate is then repeatedly distilled *in vacuo*, the middle portion only being collected; the distilled S is finely powdered, repeatedly washed with water, dried, distilled over a few small pieces of pure Zn *in vacuo* (to remove traces of S_2Cl_2), and then repeatedly distilled *in vacuo*.—3. S is ppd. by adding $HClAq$ to pure $Na_2S_2O_3Aq$, the pp. is repeatedly washed till free from chlorides, dried, distilled repeatedly, and finally distilled several times *in vacuo* (v. Monckman, *Pr.* 46, 149).

Ordinary rhombic sulphur is prepared by melting S and allowing to cool *very slowly* at 90° (Schützenberger, *C. R.* 66, 746), or by melting and throwing in a crystal of rhombic S when the liquid has cooled nearly to the crystallisation point (Gernez, *C. R.* 83, 217); also by crystallising from CS_2 ; and, in very well formed crystals, by saturating pyridine or picoline with H_2S and allowing to stand (Ahrens, *B.* 23, 2708).

Monoclinic sulphur is prepared by melting a considerable quantity of roll sulphur in a Hessian crucible, allowing to cool till a crust forms on the surface, piercing this crust, and pouring out the S that is still liquid; the walls of the crucible are covered with monoclinic crystals. This form of S can also be prepared by evaporating alcoholic solutions of $(NH_4)_2S$ (Mallard, *J.* 1885. 383; Ruys, *J.* 1884. 336; Gernez, *C. R.* 100, 1539; 101, 312); also, along with rhombic crystals, from solution of S in boiling alcohol, benzene, &c. (Maquenne, *Bl.* [2] 41, 238). By melting S, and throwing in a crystal of the monoclinic form when the liquid is near the crystallisation point, the S solidifies in monoclinic crystals (Gernez, *C. R.* 83, 217).

Soft soluble sulphur is prepared by decomposing S_2Cl_2 by water, or $Na_2S_2O_3Aq$ or a soluble polysulphide by a limited quantity of acid, or many metallic sulphides by fuming HNO_3 , or SO_2Aq by H_2SAq (Weber, *A.* 141, 432; Rose, *P.* 47, 166; Deville, *Ph. C.* 1848. 200; Fordos a. Gélis, *Ph. C.* 1854. 294). This preparation is not homogeneous; it contains both soluble and insoluble S.

Insoluble sulphur (insol. in CS_2) is prepared by heating ordinary S nearly to boiling and then cooling rapidly (most easily by slowly pouring into a large quantity of cold water), rubbing the plastic mass so obtained with a glass rod, under water, till it becomes hard, and

removing soluble S by treatment with warm CS_2 (cf. Deville, *Ph. C.* 1848. 200). Insoluble S is generally present in 'flowers of sulphur' (which is formed by rapidly cooling vapour of S); by treating this with CS_2 the soluble S is removed, and the insoluble form remains. Soluble S becomes covered with a film of the insoluble variety by exposure to sunlight or electric light when melted (Berthelot, *J. pr.* 31, 396; Lallemand, *C. R.* 70, 182). Insoluble S is also said to be obtained by decomposing $Na_2S_2O_3Aq$ by $HClAq$, dissolving the ppd. S in $CHCl_3$, evaporating, and keeping the crystals that separate for some time (for details v. Engel, *C. R.* 112, 866; Friedel, *C. R.* 112, 834). Insoluble S is also formed, mixed with the soluble variety, by the incomplete combustion of H_2S or CS_2 ; by decomposing H_2S by fuming HNO_3 , *aqua regia*, Fe_2Cl_6Aq , S_2Cl_2 , or CrO_3Aq ; and by the reaction of HNO_3Aq , SO_2 , or halogens with melted S (v. Wöhler, *A.* 86, 373; Vogel, *J. Ph.* [3] 29, 433; Schiff, *A.* 115, 68; Nöllner, *A.* 108, 19; Dietzenbacher, *C. R.* 56, 39). Insoluble S is also formed by decomposing thiosulphates by acid, or S_2Cl_2 or S_2Br_2 by water, &c., and washing the soft magma so obtained with CS_2 to remove soluble S (cf. Preparation of soft soluble sulphur, *supra*; and v. Weber, *A.* 141, 432; Rose, *P.* 47, 166; Deville, *Ph. C.* 1848. 200).

Colloidal sulphur, soluble in water, is prepared by passing H_2S into SO_2Aq at a little above 0° till all the SO_2 is decomposed, filtering, and concentrating over KOH *in vacuo*. The yellow solid so obtained is sol. water, but changes to ordinary S on keeping (Debus, *C. J.* 53, 282). According to Engel (*C. R.* 112, 866) this form of S exists in the solution obtained by adding 1 vol. $Na_2S_2O_3Aq$, saturated at the ordinary temperature, to 2 vols. $HClAq$ saturated at 25° – 30° and let cool to c. 10° , and filtering from $NaCl$ that separates. This form of S has not been isolated in a state of purity.

Regarding the formation of the varieties of S one from the other, cf. *Allotropy of sulphur*, p. 609.

Properties.—S exists in several modifications. The chief are (1) soluble in CS_2 , (2) insoluble in CS_2 , (3) soluble in water.

1. Soluble sulphur exists in two, perhaps in three, varieties, differing in S.G., crystalline form, &c.

A. *Ordinary rhombic (octahedral) sulphur* is a pale-yellow, tasteless, very brittle solid. By crystallisation from CS_2 it forms clear, yellow, transparent, lustrous crystals; the colour becomes paler at low temperatures, until at -50° the crystals are almost colourless (Schönbein, *J. pr.* 55, 161); by immersion in boiling water it becomes easily powdered (Daguin, *C. R.* 20, 1667). The crystals are derived from the fundamental form of a rhombic pyramid; about thirty varieties are known. When held in the hand S emits a distinct odour, probably because of slight volatilisation; according to Berthelot (*C. R.* 100, 1326) S is wholly volatilisable at a temperature not much above the ordinary. S is said to phosphoresce in air or O at 200° (Heumann, *B.* 16, 139). When S is rubbed it becomes strongly (negatively) electrified. S is a bad conductor of heat, and a very bad conductor of electricity; the conductivity varies slightly,

according as the light is or is not allowed to fall on the S (Monckman, *Pr.* 46, 136). Insoluble in water; easily sol. CS_2 (data at beginning of article); also sol. C_2H_6 , CHCl_3 , &c. Sol. warm conc. acetic acid (Liebemann, *B.* 10, 866); sol. liquid SO_2 (Sestini, *Z.* 1868, 718). As octahedral S changes to prismatic S near the m.p. of the former, it is evident that hot solutions of the former, in solvents which boil near to, or above, the m.p. of S must contain some prismatic S. Rhombic S slowly changes to monoclinic S when kept near its m.p. (v. p. 609, *Allotropy of sulphur*); the change is accompanied by absorption of heat (c. 650 g.-units for 32 grams S) and expansion of volume (v. Petersen, *Z. P. C.* 8, 601). According to Gernez (*C. R.* 83, 217), if a fair quantity of rhombic S is heated till melting begins on the surface, the interior portions change to microscopic monoclinic crystals, and the surface parts solidify again; this occurs only if the m.p. of monoclinic S (117.4°) is not exceeded. S melts to a clear yellow liquid; at c. 150° the liquid begins to darken and thicken; between 170° and 200° it is black, and so viscid that it does not pour out when the vessel containing it is inverted; at 330° – 340° the liquid becomes thin, but it remains dark coloured until it boils at c. 444° . These changes are accompanied by very considerable changes in the electrical conductivity of S: the conductivity is almost constant from 270° – 290° ; it increases considerably up to 340° – 350° , and then very rapidly up to the b.p. (v. Monckman, *Pr.* 46, 136). The expansion-coefficient, for each interval of 10° , decreases from 110° to 180° , and then increases gradually, but not regularly, to the b.p. (v. Moitessier, *J.* 1866, 27). Melted S may be cooled below 96° without solidifying (cf. Gernez, *C. R.* 97, 1298, 1366, 1438). For S.G., S.H., and other physical properties of S, v. beginning of this article.

B. *Monoclinic sulphur*, obtained by cooling molten S, forms transparent, yellowish brown needles; as obtained by crystallisation from solutions the crystals are nearly colourless. The crystals gradually become pale yellow and opaque, due to change into the rhombic form. The crystals are secondary forms of a monoclinic prism. This form of S is sol. CS_2 ; rhombic S crystallises from this solution; it also dissolves in alcohol, C_2H_6 , CHCl_3 , &c. On evaporation, crystals, both of rhombic and monoclinic S, separate (Maquenne, *Bl.* [2] 41, 238); monoclinic S may be recrystallised from alcoholic solution of $(\text{NH}_4)_2\text{S}$ (for references v. p. 607, *Preparation of monoclinic S*). The change of monoclinic to rhombic S is hastened by scratching with a glass rod, or by covering with CS_2 ; heated to 95.1° at 760 mm. pressure, monoclinic changes to rhombic S; the change is accompanied by appearance of heat and contraction of volume (v. p. 609, *Allotropy of sulphur*). For S.G. &c. of monoclinic S v. beginning of this article.

C. *Soft soluble sulphur* (v. *Preparation of soft soluble sulphur*, p. 607) is only partly sol. CS_2 ; it contains both soluble and insoluble amorphous S; it is a very pale yellow, or nearly white, soft, amorphous, magma that gradually hardens; when heated it gives off H_2S (Weber, *A.* 141, 432; Rose, *P.* 47, 166; Deville, *Ph. C.* 1848, 200; Fordos a. Gális, *Ph. C.* 1854, 294).

2. *Insoluble sulphur*. It is doubtful whether more than one variety of this form of S exists, or whether substances described as varieties are not merely mixtures of ordinary insoluble S with impurities.

D. *Plastic sulphur* is a citron-yellow, soft, caoutchouc-like, amorphous solid, formed by suddenly cooling molten S (v. p. 607, *Preparation of insoluble sulphur*); as prepared from ordinary S it is dark brown, but Mitscherlich (*J. pr.* 67, 369) found that the dark colour is caused by the presence of small quantities of fatty substances (cf. Dietzenbacher, *C. R.* 56, 39). The S.G. of brown, plastic S is c. 1.91 to 1.96 ; but the substance is not homogeneous; it contains both soluble and insoluble S. Plastic S soon hardens and becomes yellow, more quickly when broken up and rubbed with a glass rod, or when immersed in turpentine, or when heated to c. 100° ; heat is given out in this change (v. p. 609, *Allotropy of sulphur*). For determinations of the volumes occupied at different temperatures by plastic S v. Toepler (*W.* 47, 169).

E. *Amorphous yellow sulphur* is prepared from plastic S, or flowers of S, or the S obtained by decomposing thionates by acid, or H_2S by oxidisers &c. (v. p. 607, *Preparation of insoluble sulphur*), by washing with warm CS_2 till all soluble S is removed. This variety is an amorphous, buff-yellow powder; kept under CS_2 it seems white; when dried and rubbed it forms a loose, flocculent powder. Insol. CS_2 ; somewhat sol. CHCl_3 , Et_2O , and alcohol, according to Deville (*J. pr.* 56, 359). Unchanged at the ordinary temperature, but slowly converted to crystalline soluble S at 100° (v. Berthelot, *J. pr.* 70, 941; 71, 364; Favre, *J. Ph.* [3] 24, 344; F. a. Silbermann, *A. Ch.* [3] 34, 447). S.G. 2.046 (v. data at beginning of this article). H.C. [S.O.] = 71,990 (Petersen, *Z. P. C.* 8, 601). The accounts of this variety of S vary considerably.

F. *Black sulphur*. When S mixed with a very little oil is thrown into a hot Pt dish, a black substance is obtained which has been looked on as a modification of S (Magnus, *P.* 92, 367; 99, 145; Dietzenbacher, *P.* 124, 644; Gross, *B. B.* 1879, 788; Jones, *C. N.* 41, 244; Keller, *Bl.* [2] 4, 346). Knapp (*J. pr.* [2] 88, 48; 43, 305) has shown that the black substance contains c. 55 p.c. S and c. 83 p.c. carbonaceous matter; K. thinks it is probably a modification of S adhering to carbonised products of the oil. This substance is said to be non-volatile above the b.p. of S; it is a lustrous, amorphous, solid, insol. CS_2 , alcohol, Et_2O , oils, H_2SO_4 , &c.

8. *Colloidal sulphur soluble in water*. This form of S is said to exist in Wackenroder's solution (the milky liquid formed by passing H_2S into SO_2Aq), and also in the solution obtained by adding HClAq to $\text{Na}_2\text{S}_2\text{O}_4\text{Aq}$ (v. p. 607, *Preparation of colloidal sulphur*). This form of S has not yet been obtained free from impurities; it is a plastic, gummy, pale-yellow solid; it dissolves in water, forming a turbid liquid. By ppg. by NaCl , filtering, drying on bibulous paper, shaking with water, and repeating this treatment, Debus (*C. J.* 53, 284) obtained colloidal S that dissolved in water so as to form an almost clear, opalescent liquid, which became quite clear on warming, and turbid

on cooling. This solution yielded ordinary S on addition of several salts; evaporation left a viscous, transparent residue; the S in solution did not diffuse through a porous membrane.

Other modifications of sulphur. Various experimenters have described forms of S different from those usually recognised, but there is much doubt as to whether any of these are really distinct varieties, or merely mixtures of known varieties (*v. Maquenne, Bl. [2] 41, 238; Gernez, A. Ch. [6] 8, 266; C. R. 100, 1328; Engel, C. R. 112, 866; Berthelot, C. R. 100, 1328; Brame, C. R. 101, 538, 639*).

Allotropy of sulphur. The following table presents the best established allotropic forms of S:—

Insoluble in water.	
<i>Soluble in CS₂</i>	<i>Insoluble in CS₂</i>
Rhombic; S ₈	Plastic; S ₇
Monoclinic; S ₈	Amorphous, yellow
Amorphous, soft	
Soluble in water.	
Colloidal; S ₈	

The amorphous forms of S (soft, soluble; yellow, insoluble; and plastic, insoluble) and colloidal S have not been obtained pure; the soluble amorphous always contains insoluble, and the insoluble forms always contain soluble S; the colloidal contains S insoluble in water (*cf. Magnus, J. pr. 70, 215; 72, 48; Weber, J. pr. 70, 354*). It would probably be more accurate to make only three divisions of amorphous S: soluble in water, insol. water but sol. CS₂, insol. both water and CS₂. Berthelot (*J. pr. 71, 364; 78, 244*) holds that there are two main varieties of S: soluble in CS₂, and insoluble in CS₂. S separated from compounds wherein it acts as the positive radiole, or part of the positive radiole (*e.g. S₂Cl₂, SO₂Aq*), is insoluble, according to B.; whereas when separated from compounds wherein it forms the negative radiole, or part of the negative radiole (*e.g. H₂S, K₂S*), S is soluble in CS₂. B. distinguishes the two varieties of S as electro-positive and electro-negative. Cloëz (*J. pr. 74, 266; 78, 241*) asserts that insoluble S is obtained from S₂Cl₂ when this compound is rapidly shaken with water, but that soluble (crystalline) S separates from the same compound by the gradual action of moist air; and that insoluble S is obtained by electrolysing H₂SAq provided the electrolysis is rapid (*cf. Weber, P. 141, 432*).

Any form of S changes gradually to the rhombic crystals (S₈); this change is hastened by raising the temperature within certain limits. Berthelot (*J. pr. 71, 360*) examined the amount of soluble (crystalline) S changed to insoluble at different temperatures; he found that rhombic S heated to 180°–140° and rapidly cooled was still wholly soluble in CS₂, that much insoluble S was formed by heating to c. 170°, and not much more at c. 230°. These results can be taken only as very roughly approximate, on account of difficulties in cooling, &c. (*cf. Deville, J. pr. 56, 865; Frankenheim, J. pr. 54, 486*). According to experiments of Gernez (*C. R. 97, 1398, 1366, 1433; 100, 1343, 1382*), Ruys (*R. T. C. 3, 1*), and Reicher (*J. 1885. 247*), monoclinic S (S₈) changes to rhombic (S₈) in c. 12 days at –36°

to –15°, and in c. 30 minutes at 40°. Reicher (*R. T. C. 2, 246; Z. K. S, 598*) says that the temperature of change of S₈ to S₇ is 95°–9° at the ordinary pressure, and rises .05° for each increase of 1 atmosphere pressure; at 96°–1° S₈ changes to S₇, and at 96°–1° S₇ changes to S₆. The change of any form of S to rhombic crystals is accompanied by the appearance of heat and contraction of volume; the data for the heats of combination of S₈, S₇, and amorphous insoluble S give c. 650 gram-units as the quantity of heat produced when 82 grams S₈ change to S₇, and c. 900 gram-units for the change of 82 grams insoluble amorphous S to S₈ (*cf. Berthelot, C. R. 70, 941; and Mitscherlich, P. 88, 828*). By keeping S molten for some time at 100°, and then inducing crystallisation by dropping in a crystal of S, either rhombic or monoclinic crystals can be obtained, according as the crystal dropped in is rhombic or monoclinic. When rhombic S is melted and allowed to cool under ordinary conditions the solid contains both S₈ and S₇; if the cooling is rapid, some amorphous S (both soluble and insoluble) is also produced; hence ordinary 'flowers of sulphur,' formed by rapidly cooling S vapour, contains both soluble and insoluble S, and generally also, when freshly prepared, both rhombic and monoclinic crystals. The crystals of S that separate from solutions in CS₂ are rhombic; both forms of crystals separate from solutions in alcohol, C₂H₅, CHCl₃, &c.; and monoclinic crystals separate from solutions in alcoholic (NH₄)₂S. Light brings about the change of soluble into insoluble S; if bright sunlight, or light from the electric arc, falls on molten S at c. 130°, a film of insoluble S is produced. Similarly, light concentrated by a lens and directed on to a conc. solution of S in CS₂, quickly causes the formation of a speck of insoluble S, which soon increases in size till the liquid becomes turbid (Berthelot, *J. pr. 81, 396; Lallemand, C. R. 70, 162*). No differences have been observed between the chemical behaviour of the soluble and insoluble varieties of S (*v. Schmitz-Dumont, B. 25, 2659*).

Atomic weight of sulphur. The at. w. of S has been determined (1) by converting AgCl into Ag₂S (Berzelius, *P. 65, 319 [1845]; Svanberg a. Struve, J. pr. 44, 320 [1848]*); (2) by reducing Ag₂SO₄ to Ag by H (Struve, *A. 80, 203 [1851]; Stas, Stas R. 125 [1860]*); (3) by direct synthesis of Ag₂S (Dumas, *A. Ch. [8] 55, 147 [1859]; Stas, Stas R. 58 [1860]*); (4) by determining S.H. of S (Kopp, *T. 1865. 71*); (5) by determining V.D. of, and analysing, SH₂, SO₂, S₂Cl₂, &c.

Molecular weight of sulphur. The V.D. determinations of Dumas (*A. Ch. [2] 50, 170*) gave c. 95 at 450°–500°, pointing to the molecular formula S₈; Bineau (*C. R. 49, 799*) found V.D. 39 from 714° to 743°, and 34 between 840° and 1160°, indicating the molecular weight S₈. The determinations by Deville a. Troost (*C. R. 56, 891*) at 860°–1040° confirmed the number 32 and the molecular weight S₈. Troost (*C. R. 95, 80*) got the number 42.5 at 665°, indicating a mol. w. of c. S₈ (V.D. corresponding to S₈ = 48). In 1888 Biltz determined V.D. of S at intervals from 468° to 606°, and got results ranging from 113.2 at the lower temperature to 68.4 at the higher (S₈ = 112; S₈ = 64). The V.D. constantly decreased as temperature rose; the V.D. was constant only between 502° and 524°, but the

values were between those calculated for S_8 and S_2 . Biltz concluded that the only molecules which exist as gas through any considerable range of temperature have the composition S_8 . Ramsay (*Z. P. C.* 8, 67 [1889]) thought that Biltz's results did not negative the existence of gaseous molecules more complex than S_8 . Schall (*B.* 23, 1701 [1890]) got numbers for V.D. varying from 115 to 122, at 573° and pressures from 10–20 mm., in an atmosphere of N or CO_2 ; S. concluded that molecules S_8 probably exist in the vapour of S. Riecke (*Z. P. C.* 6, 430 [1890]) regarded the decrease of V.D. with increasing temperature as a dissociation of S_8 to S_6 and S_2 ; by making certain assumptions, his calculated results agreed well with the experimental numbers of Biltz. In 1888 Paterno a. Nasini (*B.* 21, 2158) determined the depression in the freezing-point of benzene caused by dissolving S therein; their results indicated S_8 as the molecular formula of S in solution in benzene. By determining the increase in the boiling-point of CS_2 produced by dissolving S in that solvent, Beckmann (*Z. P. C.* 5, 76 [1889]) got values for the mol. w. of S varying from 245 to 280 ($S_8 = 256$). Sakurai also used this method in 1892 (*C. J.* 61, 989); his values for mol. w. of S in CS_2 varied from 252.3 to 254.9. From observations of the effect of dissolving S in naphthalene on the f.p. of the solvent, Hertz (*Z. P. C.* 6, 858 [1890]) concluded that the mol. w. of S in solution in naphthalene is 256 = S_8 . Helff (*Z. P. C.* 12, 196) in 1893 also got S_8 for mol. w. of S in CS_2 , and in molten P. These results leave little doubt that molecules S_8 exist in solutions of S in CS_2 and in naphthalene, and S_8 in solutions in benzene; that molecules of greater complexity than S_8 —probably as complex as S_8 —exist in S vapour, but these are stable only through a small range of temperature, and gradually dissociate as temperature rises until all the molecules existing above c. 700° have the composition S_8 . Biltz a. Meyer (*B.* 22, 725 [1889]) have shown that the V.D. of S corresponds with the mol. w. S_2 up to 1600°–1700°.

Reactions.—1. Reacts with water at 100° to form H_2S . Cross a. Higgin (*C. J.* 35, 249; *B.* 16, 1195) found that the solution contained thionic acids; they supposed that these were produced by reactions between the H_2S and SO_2 formed by the action of the S on the water (*cf.* Payen, *J. Ph.* 8, 871; Mulder, *J.* 1858, 84; Meyer, *C. R.* 74, 195; Gélis, *C. R.* 56, 1004). Senderens (*Bl.* [3] 6, 800) regarded the production of H_2S as due to interactions between the S and the glass vessels employed; C. a. H. (*C. J.* 35, 252) found H_2S was produced when dilute H_2SO_4 was used in place of water, and they concluded that the alkaline constituents of the glass were without influence. Becquerel (*C. R.* 56, 287) says that when water containing S in suspension is electrolysed, H_2SO_4 forms at the positive, and H_2S at the negative, electrode (*cf.* Colson, *Bl.* [2] 34, 66). When S is moistened with water and let stand in the air, H_2SO_4 is said to be produced (Polacci, *C. C.* 1884, 464; Böhm, *M.* 8, 224).—2. S is oxidised to H_2SO_4 by heating with nitric acid, aqua regia, or potassium chlorate and hydrochloric acid.—3. Conc. hot sulphuric acid is reduced, giving off SO_2 .—4. Conc. hydriodic acid gives H_2S and I (I de-

composes dilute H_2SAq to $HIAq + S$).—5. Chlorosulphonic acid when heated with S produces S_2Cl_2 , SO_2 , and HCl (Heumann a. Köchlin, *B.* 15, 416).—6. S dissolves in boiling alkali solutions, also in molten alkalis and alkaline carbonates, to form mixtures of polysulphides and thiosulphates. Boiling ammonia solution forms polysulphides; heated in a sealed tube above 100° some $(NH_4)_2S_2O_8$ is produced (v. Brunner, *D. P. J.* 150, 371).—7. Sulphur trioxide dissolves S, forming a blue solution of S_2O_3 (v. Sulfur oxides).—8. Carbon dioxide reacts with boiling S to form COS (Cossa, *B.* 1, 117; Berthelot, *Bl.* [2] 40, 864). The same compound is produced by volatilising S, by an electric current, in carbon monoxide (Chevrier, *C. R.* 69, 56).—9. $PSCl_4$ is formed by the interaction of S and phosphorus trichloride at 130° (Henry, *Bl.* 13, 495). Phosphorus pentachloride forms PCl_4 and S_2Cl_2 (Goldschmidt, *C. C.* 1881, 489).—10. S decomposes many sulphates and carbonates at high temperatures, forming sulphides and SO_2 , or CO_2 (v. Sestini, *Bl.* [2] 34, 490; Berthelot, *Bl.* [2] 40, 864).—11. Solutions of salts are very often reduced by boiling with S, sulphides being generally ppd. (v. Vortmann a. Padberg, *B.* 22, 2642; and, more fully, Senderens, *Bl.* [3] 6, 800; 7, 511).

Combinations.—1. Sulphur combines directly with most of the elements. The binary compounds of S—with the exception of those with Br, Cl, F, I, or O, and also compounds of S with more than one other element (except these be some of the five just mentioned)—are described under the least negative of the component elements; e.g. compounds of S with P and Cl are described (as sulphochlorides) under Phosphorus. For the conditions of formation of the binary compounds of S reference must be made to the various elements, except in the cases of bromide, chloride, fluoride, iodides, and oxides of S, which are described in this article in their proper (alphabetical) places.—2. Chlorine monoxide Cl_2O is said to combine directly with S (suspended in S_2Cl_2), at -12°, to form $SOCl_2$ (Wurtz, *C. R.* 62, 460).

Sulphur, acids of. Reference should be made to HYDROGEN SULPHIDE, vol. ii. p. 725; SULPHUR OXYACIDS, this vol. p. 619; SULPHUR OXYACIDS, NITROGEN DERIVATIVES OF, this vol. p. 619; SULPHOCYANIC ACID, vol. ii. p. 303; SULPHONIC ACIDS AND DERIVATIVES, this vol. p. 599; THIOCARBONIC ACID, vol. i. p. 703. For acids, and salts of acids, containing S and P, and S, P and O, v. PHOSPHORUS SULPHIDES, this vol. p. 145 (beginning of article); also PHOSPHOROUS SULPHIDE, Reactions 7 and 8 (p. 146), PHOSPHORIC SULPHIDE, Reaction 8, and also end of that article (p. 147).

Sulphur, bromides of. It is very doubtful whether any definite compound of S and Br exists. Powdered S dissolves in Br with evolution of a little heat; the deep ruby-red liquid begins to distil over at c. 60° and the thermometer rises steadily to c. 190°, when it ascends slowly to c. 200°, after which it steadily rises till S remains; the fraction coming over at 190°–200° agrees fairly in composition with the formula S_2Br_2 (Pattison Muir, *C. J.* 28, 845). M. found that by passing CO_2 through a solution of S in excess of Br for some hours, at 15°, 50°, and 90°, the residual liquid had nearly the com-

position S_2Br_2 ; Hannay, however, by passing air through such a liquid for 400–500 hours found that the whole of the Br was removed and that pure S remained (*C. J.* 33, 284; 35, 16). It is, however, possible that at the temperature of this experiment, c. 15° , dissociation of S_2Br_2 was induced by the stream of air. H. also found that the vapour given off by the supposed S_2Br_2 , even at 0° , showed the absorption-spectrum of Br. Spring a. Lecrenier (*Bl.* [2] 45, 867) examined the reaction of the supposed S_2Br_2 with K_2SO_4 . S. had before shown that S_2Cl_2 and K_2SO_4 produce KCl and $K_2S_2O_8$; but Cl and S acting as free elements produce K_2SO_4 , KCl, $K_2S_2O_8$, and SO_2 . S_2Br_2 ought then to produce KBr and $K_2S_2O_8$, whereas S and Br would form K_2SO_4 , KBr, $K_2S_2O_8$, and SO_2 ; by determining the quantities of the products S. a. L. calculated that the supposed S_2Br_2 contains c. 27 p.c. of the elements uncombined. Various reactions of the supposed S_2Br_2 are described in the memoirs already referred to (v. also Rose, p. 44, 327; Michaelis, *J. Z.* 6, 297; Ogier, *C. R.* 92, 922).

Sulphur, chlorides of. Three compounds of S and Cl are known: S_2Cl_2 , SCl_2 , and SCl_4 . These compounds are liquids; S_2Cl_2 boils unchanged at c. 138° , SCl_2 begins to decompose to S_2Cl_2 and Cl at c. 10° , and the decomposition of SCl_4 to SCl_2 and Cl begins at c. -20° .

SULPHUR MONOCHLORIDE S_2Cl_2 . (*Sulphur protochloride, Sulphur sulphochloride, Sulphothionyl chloride, Thio-thionyl chloride.*) Mol. w. 134.7. Boils at $138-139^\circ$; S.G. $\frac{4}{15}$ 1.70941, S.G. at b.p. 1.49201 (Thorpe, *C. J.* 37, 356). S.V. 90.28 (T., *l.c.*, p. 372). V.D. 68.4 (Dumas, *A. Ch.* [2] 49, 204; Marchand, *J. pr.* 22, 507). μ_{H_2} = 1.64449 (Haagen, *P.* 131, 117). H.F. [S_2Cl_2] (from S_2) = 14,257 (*Th.* 2, 810); 17,600 (Ogier, *C. R.* 92, 922).

Formation.—1. By the interaction of S and Cl.—2. By distilling S with 9 parts $SnCl_2$ or 8.5 parts $HgCl_2$.—3. By reacting on PCl_5 with S (Goldschmidt, *C. C.* 1881, 489).—4. By decomposing $PSCl_3$ by Cl or by heating to redness.—5. By the interaction of P_2S_5 and $SOCl_2$, the other product being P_2O_5 (Carius, *A.* 106, 831).—6. By the action of CS_2 on ICl_3 (Weber, *P.* 128, 459).

Preparation.—A stream of dry Cl is passed into a flask, or retort, containing S (flowers or sticks) until most, but not quite all, S is dissolved to a yellowish-red liquid, the vessel being gently warmed. The liquid is repeatedly distilled until it boils constantly at $138^\circ-139^\circ$. If the passage of Cl is continued until the S is completely dissolved, the liquid must be distilled from a little S (to decompose SCl_2 quickly).

Properties.—A yellowish-red, oily liquid, with a very characteristic, rather disagreeable, odour and an acid taste; the vapour affects the mucous membranes rapidly, causing tears, and affecting the breathing. Does not become viscid at -75° (Haase, *B.* 26, 1052). Fumes in air. Dissolves in CS_2 and C_2H_6 , also in alcohol and ether with decomposition. S_2Cl_2 dissolves large quantities of S; solution of S_2Cl_2 , containing free S, in CS_2 is used for vulcanising (v. *DICTIONARY OF APPLIED CHEMISTRY*, vol. iii. p. 706).

Reactions and Combinations.—1. S_2Cl_2 sinks in water, and then decomposes, giving $HClAq$,

SO_2Aq , and S, with a little H_2SAq , $H_2S_2O_8Aq$, and some of the thionio acids.—2. *Hydrogen sulphide* produces HCl and S; *hydrogen iodide* reacts at the ordinary temperature to form HCl , I, S_2I_2 , and then H_2S (Hautefeuille, *Bl.* [2] 7, 198).—3. By passing S_2Cl_2 vapour, mixed with air or oxygen, through a red-hot tube, SO_2 , SO , and Cl are formed (Donny a. Mareska, *C. R.* 20, 817; Spring a. Lecrenier, *Bl.* [2] 45, 867).—4. Heating with phosphorus produces PCl_3 , $PSCl_3$, and S if a little P is used; or PCl_5 , P sulphides, and red P if much P is used (Wöhler a. Hiller, *A.* 93, 274; Chevrier, *C. R.* 63, 1003).—5. Heated with many metals, S_2Cl_2 gives metallic chlorides and S; the more volatile the metallic chloride the more readily does the reaction occur (v. Chevrier, *C. R.* 64, 302).—6. S_2Cl_2 combines with chlorine, forming SCl_2 and SCl_4 (*q.v. infra*). Br and I are absorbed by S_2Cl_2 ; according to Evans a. Ramsay (*C. J.* 45, 65) no compound is formed with Br.—7. With oxides of arsenic and antimony S_2Cl_2 forms $AsCl_3$ and $SbCl_3$, giving off SO_2 and separating S; selenium dioxide produces Se_2Cl_2 and SO_2 ; oxides of phosphorus, boron, and silicon do not react (Prinz, *A.* 223, 355).—8. S_2Cl_2 absorbs sulphur trioxide, below 0° , forming a brownish-yellow liquid, from which excess of SO_3 crystallises out; a little above 6° SO_2 is given off, rapidly at 10° ; $S_2O_3Cl_2$ is formed on distillation (Rose, *P.* 44, 291).—9. By passing vapour of S_2Cl_2 along with the vapours from sulphonic acid through a hot tube, SO_2 , H_2S , S, HCl , and Cl are produced (Braut a. Poggiale, *J. Ph.* 21, 140).—10. Heating S_2Cl_2 with sulphates generally produces SO_2Cl_2 , chlorides, S, and SO_3 ; heated with sulphuryl chloride to 250° , $S_2O_2Cl_2$ is formed (v. Schneider, *J. pr.* 104, 83; [2] 32, 18; Demarçay, *C. R.* 92, 726).—11. S_2Cl_2 combines with ammonia gas to form $S_2Cl_2 \cdot 4NH_3$, stable in air, sol. alcohol, decomposed by water giving NH_4ClAq , $(NH_4)_2S_2O_8Aq$, and S (Braut a. Poggiale, *J. Ph.* 21, 140).—12. Reacts with organic compounds containing oxygen, generally forming Cl compounds and small quantities of S compounds, and also HCl , SO_2 , and S.—13. Combines with unsaturated hydrocarbons; e.g. with C_2H_4 , forms $C_2H_4S_2Cl_2$.

SULPHUR DICHLORIDE SCl_2 . Mol. w. (in solution in benzene or acetic acid) 102.72. S.G. 1.6482 at 15.4° (Costa, *G. Z.* 367). μ_{H_2} = 1.5716 (Costa, *l.c.*). No constant b.p. (*v. infra*). This compound was prepared by H. Rose in 1831 (*P.* 21, 431; 27, 107); the experiments of Dumas (*A. Ch.* [2] 49, 204) and Marchand (*J. pr.* 22, 507) led to its recognition as a definite compound (v. also Carius, *A.* 106, 291); Hübner a. Guerout (*Z.* 1870, 455) isolated the compound satisfactorily, and their results were confirmed by Thorpe a. Dalzell, in 1871 (*C. N.* 24, 159). Costa, in 1890 (*G. Z.* 20, 867), determined the mol. w. of the compound in solution.

Preparation.—Dry Cl is led into S_2Cl_2 , surrounded by a freezing mixture, until the liquid becomes deep red; excess of Cl is removed by a stream of dry CO_2 . The temperature must not rise above 6° ; the vessel containing the S_2Cl_2 should be kept filled with Cl continually, and should not be exposed to direct sunlight (H. a. G., *l.c.*; C., *l.c.*; T. a. D., *l.c.*; also Soubeiran *A. Ch.* [2] 67, 64; Michaelis, *A.* 170, 1).

Properties.—A thin, dark, brownish-red, liquid, with smell and taste like S_2Cl_2 ; does not solidify at -80° ; gives off Cl when exposed to sunlight, and should, therefore, be kept in a sealed tube in the dark. Easily decomposed by heat to S_2Cl_2 and Cl; Michaelis (*B.* 6, 995) gives a table showing amount of dissociation from 20° to 180° ; the temperature whereat 50 p.c. of the SCl_2 is dissociated is c. 86° . SCl_2 reddens dry litmus paper. The depression of the freezing-point of benzene or glacial acetic acid by solution therein of SCl_2 , shows that the mol. w. agrees with the formula SCl_2 (Costa, *G.* 20, 367).

Reactions and Combinations.—1. *Heat*, or direct sunlight, causes dissociation to S_2Cl_2 and Cl (*v. supra*, **Properties**).—2. *Water* produces HCl and $H_2S_2O_4$.—3. Oxidised violently by nitric acid to HCl and H_2SO_4 .—4. *Ammonia* solution produces NH_4Cl , N , and S ; *ammonia* gas combines to form $SCl_2 \cdot 2NH_3$ and $SCl_2 \cdot 4NH_3$, soluble, unchanged, in absolute alcohol and ether (Soubeiran, *A. Ch.* [2] 67, 74).—5. *Thionyl chloride* ($SOCl_2$), when heated with SCl_2 , forms S_2OCl_4 (Ogier, *Bl.* [2] 37, 293).—6. *Alkali sulphides* produce chlorides and trithionates (Spring a. Leorenier, *Bl.* [2] 45, 367).—7. *Some metals*, e.g. Cu, Fe, K, react with SCl_2 , with production of heat and light, and formation of chlorides and sulphides.—8. Combines with *arsenious chloride*, forming $AsCl_3 \cdot SCl_2$, according to H. Rose (*P.* 27, 107).—9. SCl_2 reacts with *oxygenised carbon compounds* similarly to, but more readily than, S_2Cl_2 ; it combines with several *unsaturated hydrocarbons* (*v.* Heintz, *A.* 100, 370; Guthrie, *C. J.* 12, 109).

SULPHUR TETRACHLORIDE SCl_4 . This compound exists only at temperatures under -20° . The molecular weight is probably 178.46 (SCl_4).

Preparation.— S_2Cl_2 is cooled to below -20° (c. -22°) and a slow stream of dry Cl is passed in until absorption of Cl ceases. Michaelis a. Schifferdecker (*B.* 6, 993) found that 67.5 g. S_2Cl_2 , kept at -20° to -22° , absorbed 106 g. Cl in 10 hours, that absorption of Cl then ceased, and that the liquid had the composition SCl_4 .

Properties.—A mobile, yellowish-brown liquid; when removed from the freezing mixture used in the preparation, the liquid gives off Cl, and boils with an absorption of much heat. M. a. S. give the following data showing the dissociation of SCl_4 to SCl_2 and Cl:—

Temp.	P.c. SCl_2	P.c. SCl_4
-22°	100.0	0.0
-15	41.95	58.05
-10	27.62	72.38
-7	21.97	78.03
-2	11.93	88.07
$+0.7$	8.87	91.13
$+6.2$	2.43	97.57

Reactions.—1. *Water* causes rapid decomposition to HCl and SO_2 and S , with more or less S according to the mass and temperature of the water.—2. With *sulphur trioxide*, in the ratio $SCl_4:SO_3$, the products are $SOCl_2$ and $S_2O_3Cl_2$, in the ratio $SCl_4:2SO_3$, the products are $SOCl_2$, SO_2 , and Cl (M. a. S., *l.c.*; also *B.* 5, 924). *Sulphur dioxide* does not react.—3. *Chlorosulphonic acid* reacts at a low temperature to form $S_2O_3Cl_2$ and HCl (M. a. S., *B.* 6, 996).—4. With *some hydroxylic organic compounds*, e.g. C_2H_5OH and

$C_2H_5CO.OH$, OH is replaced by Cl and $SOCl_2$ is formed.

Combinations.—1. Compounds of SCl_2 with several *metallic chlorides* are produced by warming the chlorides with S_2Cl_2 , and passing in Cl; the compounds $2AlCl_3 \cdot SCl_2$, $AlCl_3 \cdot SCl_2$, and $2TiCl_3 \cdot SCl_2$ are formed thus (Weber, *P.* 104, 421; Rose, *P.* 42, 517; Casselmann, *A.* 83, 267). The compound with $AlCl_3$ may be distilled in a closed \wedge shaped tube; the other two compounds give off Cl when heated. The compounds $SbCl_3 \cdot 8SCl_2$ and $SnCl_4 \cdot 2SCl_2$ are produced by passing Cl over SnS_2 and Sb_2S_3 respectively (*R., l.c.*; *C., l.c.*).—2. With *iodine trichloride* forms $ICl_3 \cdot SCl_2$ (Weber, *P.* 128, 459; cf. Jaillard, *A. Ch.* [3] 59, 454, who gives the composition $SCl_2 \cdot 2ICl_3$). Prepared by passing Cl into I dissolved in CS_2 , till the liquid is wine-red, cooling, and drying the red-yellow, prismatic, very deliquescent, crystals, in a tube in a stream of dry Cl. Also formed by passing Cl into a mixture of 2 pts. S and 1 pt. I. Melts to a brown liquid when heated in a closed tube; heated in an open tube forms Cl, ICl , and S_2Cl_2 ; decomposed by water or dilute HNO_3 and Aq .

Sulphur, chloronitride of, S_2ClN ; *v.* NITROGEN SULPHOCHLORIDE, vol. iii. p. 571.

Sulphur, cyanides of, *v.* CYANOGEN, SULPHIDES, vol. ii. p. 358.

Sulphur, fluoride of. According to Gore (*Pr.* 20, 70 [1871]) the heavy colourless gas produced by fusing AgF with S is a fluoride of S. This gas is not liquefied at 0° , at the ordinary pressure; it fumes in the air, and attacks glass; no analyses are given by G.

Sulphur, haloid compounds of. The most stable of these compounds belong to the forms S_2X_2 ; where $X = Cl, Br, \text{ or } I$. The chloride S_2Cl_2 may be distilled unchanged; the bromide, S_2Br_2 , is exceedingly easily decomposed if, indeed, it has been isolated; the iodide, S_2I_2 , has been very slightly examined. The compounds SCl_2 and SCl_4 also exists; the former at temperatures below c. 10° , and the latter below c. -20° . The compound SI_2 perhaps exists; it gives up I at the ordinary temperature. The only haloid compound of S that has been gasified unchanged is S_2Cl_2 .

Sulphur, hydrides of, SH_2 and (?) S_2H_2 ; *v.* HYDROGEN SULPHIDES, vol. ii. p. 725.

Sulphur, nitride of, SN ; *v.* NITROGEN SULPHIDE, vol. iii. p. 570.

Sulphur, iodides of. S and I probably combine when heated together, but no definite compound has been isolated by this method (*cf.* Gay-Lussac, *J.* 48, 372; H. Rose, *P.* 27, 115; Lamers, *J. pr.* 84, 349; Sestini, *J.* 1863, 153; Wheeler a. Lüdeking, *Zr.* 26, 602).

SULPHUR MONO-IODIDE SI_2 . Guthrie (*C. J.* 14, 57) obtained this compound by placing $2\frac{1}{2}$ parts EtI and 1 part S_2Cl_2 in a sealed tube, opening after 12 hours, evaporating $EtCl$ by warming with the hand and removing excess of EtI by gently warming; the SI_2 crystallised out in lustrous crystals resembling I. (One analysis is given, but no full description of properties.)

Ogier (*C. R.* 92, 922) gives H.F. [S, P] (from gases) = 10,800.

SULPHUR HEXA-IODIDE SI_6 . This compound is said to be formed by slowly evaporating, at a low temperature, a solution of I with slight excess of S in CS_2 . Grey-black crystals; resembling, and isomorphous with, I; I evaporates on exposure to air and eventually only S remains; alcohol, conc. KOH aq. or KIAq, also withdraws all I (G. vom Rath, *P.* 110, 116; Lamers, *J. pr.* 84, 349). It is very doubtful whether the crystals examined by vom Rath were a compound or only I retaining a little S.

By passing H_2S into a dilute solution of $KCl.ICl_3$, Lamers (*l.c.*) obtained an orange-red pp. which dried in an exsiccator to a brown amorphous mass containing S and I in the ratio $S:I_2$.

By subliming SnS_2 with I, Schneider (*J.* 1860, 186) obtained a compound to which he gave the composition $SnSI_2.SI_2$.

Sulphur, iodochloride of, $SICl_3$ (= $SnCl_3.ICl_3$)

v. SULPHUR TETRACHLORIDE, Combinations No. 2.

Sulphur, oxides of. Four compounds have been isolated; S_2O_3 , SO_2 , SO_3 , and S_2O_7 . S and O combine directly to form SO_2 and SO_3 ; S dissolves in SO_2 to form S_2O_3 ; S_2O_7 is formed by the action of an electric discharge on a mixture of SO_2 and O, or SO_2 and O.

SULPHUR SESQUIOXIDE S_2O_3 (Hyposulphurous anhydride). The production of a blue substance, on distilling fuming H_2SO_4 and S, was noticed by Buchholz in 1804 (*Gehlen's J.* 3, 7); Vogel, in 1812, obtained the blue body by bringing together S and SO_2 (*S.* 4, 121); the substance was examined by Wach (*S.* 50, 1), Berzelius (*Lehrbuch* [5th edit.] 1, 485), and Stein (*J. pr.* [2] 6, 172). Weber, in 1875, isolated the compound and found its composition to be S_2O_3 (*P.* 156, 531).

S_2O_3 is prepared by adding well-dried flowers of sulphur, little by little, to SO_2 quite free from H_2SO_4 , more S being added when the previous quantity has all combined. The process is conveniently conducted in a test tube, covered with a small porcelain crucible to exclude moisture, and plunged into water cooled to $c. 12^\circ$; the S disappears in the SO_2 , and blue drops are formed; the tube should be tilted so that the blue drops come into contact with the sides of the tube where they form a thin crust (if the drops solidify as they float in the SO_2 , the solid S_2O_3 retains SO_2 , from which it cannot be freed). When $c. 1$ g. S has been added, excess of SO_2 , (which should be colourless) is poured off, the last traces being removed by gently and carefully warming not above 35° ; the solid S_2O_3 is scraped out of the tube by a glass rod.

S_2O_3 is a blue-green solid, consisting of a mass of microscopic crystals. Insoluble pure SO_2 ; if a little H_2SO_4 is present the S_2O_3 dissolves to a deep-blue liquid. Melts with decomposition; decomposes slowly in dry air, quickly on heating, to SO_2 and S; deliquesces in moist air to a brown liquid from which S soon separates; reacts violently with water, giving H_2SO_4 , SO_2 aq., $H_2S_2O_4$ aq., polythionic acids, and S; decomposed also by alcohol and ether, with separation of S, also by ordinary H_2SO_4 .

S_2O_3 may be regarded as the anhydride of $H_2S_2O_4$; although the acid has not been ob-

tained from the oxide, nor the oxide from the acid.

For the compounds $SSeO_3$ and $STeO_3$, v. *Selenion thio-oxide* (p. 441) and *Tellurium thio-oxide* (under TELLURIUM OXIDES).

SULPHUR DIOXIDE SO_2 (Sulphurous oxide. Sulphurous anhydride. Thionyl oxide). Mol. w. 63.9. Melts at $c. -76^\circ$ (Faraday, *T.* 1845, 155); $c. -80^\circ$ (Mitchell, *A.* 87, 356). Boils at $c. -10^\circ$ (Bunsen, *P.* 46, 97; Andréeff, *J.* 1859; Pictet, *C. C.* 1877, 81). S.G. (liquid) 1.4911 at -20.5° ; 1.4384 at -2.08° ; 1.4252 at $+2.8^\circ$; 1.3769 at 20° ; 1.3258 at 88.65° (Andréeff, *A. Ch.* [3] 56, 317); 1.4338 at 0° ; 1.2872 at 52° ; 1.1845 at 82.4° ; 1.1041 at 102.4° ; .956 at 180.3° ; .7317 at 151.75° ; .52 at 156° (Cailletet & Mathias, *C. R.* 104, 1563). S.G. (gas at 0° and 760 mm.) 2.2639 (Leduc, *C. R.* 117, 219). V.D. 32.23 (Gay-Lussac, Berzelius, Buff; Biltz, *B.* 21, 2769). S.H. (equal wt. water = 1) .1544; (equal volume air = 1) .3414 (Regnault, *J.* 1863, 84). Ratio of S.H. constant pressure to S.H. constant volume = 1.2562 (Müller, *W.* 18, 94). C.E. .00423 for 1° between 0° and 10° ; .004005 10° to 20° ; .003846 at 50° ; .003757 at 100° ; .003718 at 150° ; .003695 at 200° ; .003685 at 250° (Amagat, *C. R.* 73, 183; cf. *C. R.* 68, 1170). Leduc (*C. R.* 117, 219) gives C.E. between 0° and 20° as .00396. For C.E. of liquid SO_2 , v. Drion (*A. Ch.* [3] 56, 5) and Andréeff (*A.* 110, 1). The

ratio $\frac{PV}{P_1V_1} > 1$; Amagat (*l.c.*) gives these values,

1.0185 at 15° ; 1.0110 at 50° ; 1.0054 at 100° ; 1.0032 at 150° ; 1.0021 at 200° ; 1.0016 at 250° . H.F. [S_2O_3] = 71.070 from solid rhombic S; 71.720 from solid monoclinic S (*Th.* 2, 247). Heat of liquefaction of gaseous SO_2 = 5644 (Favre, *A. Ch.* [5] 1, 209). Critical temperature = 156° (Cailletet & Mathias, *C. R.* 104, 1563); 155.4° (Sajotscheffski, *P. B.* 1879, 741); 157.2 – 161° (Ladenburg, *B.* 11, 821). Heat of vaporisation of liquid SO_2 , at 0° = 91.2 , at 60° = 69 (C. a. M., *l.c.*; cf. Chappuis, *C. R.* 104, 897). Regnault (*C. R.* 50, 1063) gives vapour pressures as follows:

Temp.	Vap. pressure	Temp.	Vap. pressure
-25°	873.79 mm. Hg	30°	8181.80 mm. Hg
-20	479.46 "	40	4670.23 "
-10	762.49 "	50	6220.01 "
0	1165.06 "	60	8123.80 "
$+10$	1719.55 "	65	9221.40 "
20	2462.05 "		

Vapour-pressure at critical temp. = 78.9 atmos. (Sajotscheffski, *P. B.* 1879, 741). S. in water between 0° and 20° (gaseous SO_2) = 79.789 – $2.6077t + .029849t^2$; 1 vol. of the saturated SO_2 aq. contains 68.861 – $1.87025t + .01225t^2$ vols. SO_2 ; S. (water) between 21° and 40° = 75.182 – $2.1718t + .01903t^2$; 1 vol. of the saturated SO_2 aq. contains 60.952 – $1.88898t + .00726t^2$ vols. SO_2 (Bunsen & Schönfeldt, *A.* 95, 2). S. in alcohol, at 760 mm. = 328.62 – $16.95t + .3119t^2$; S.G. of solution = 1.1197 – $.014091t + .000257t^2$ (Carius, *A.* 94, 148). Sims (*C. J.* 14, 1) gives the table on the next page, which presents both the weight of SO_2 , in grams and the volume of gaseous SO_2 , in c.c. dissolved by unit weight of water at the normal pressure and different temperatures:—

Temp.	Grams SO ₂ c.c. SO ₂	
	absorbed by 1 g. water at 760 mm.	
8°	·168	58·7
12	·142	49·9
16	·121	42·2
20	·104	36·4
24	·092	32·3
28	·083	28·9
32	·078	25·7
36	·065	22·8
40	·058	20·4
44	·053	18·4
48	·047	16·4
50	·045	15·6

The quantity of SO₂ dissolved by a given weight of water varies with pressure, and only at c. 40° and upwards is the quantity proportional to the partial pressure of the gas (v. Sims, *C. J.* 14, 1). For S.G. and composition from ·5 to 10 p.c. of SO₂ Aq v. Anthon (*C. C.* 1860. 744); also Giles a. Schearer (*S. C. I.* 4, 303). [SO₂ Aq] = 7,700 (gaseous SO₂) (*Th.* 2, 249); 1500 (liquid SO₂) (Berthelot, *C. R.* 96, 142, 208; Chappuis, *A. Ch.* [2] 19, 21). H₂SO₄ Aq absorbs the following quantities of gaseous SO₂ (Kolb, *D. P. J.* 209, 270; cf. Dunn, *C. N.* 43, 121; 45, 270):—

S.G. H ₂ SO ₄ Aq	Kilos. SO ₂ per kilo. acid	Litres SO ₂ per litre acid
1·841	·009	5·8
1·839	·014	8·9
1·540	·021	11·2
1·407	·032	15·9
1·227	·068	29·7

SO₂ is absorbed by charcoal; 1 c.c. charcoal = 1·57 g. was found by Favre (*A. Ch.* [5] 1, 209) to absorb 165 c.c. SO₂. Camphor absorbs c. 308 times its vol., glacial acetic acid c. 318 times, SO₂Cl₂ c. 187 times, its volume of SO₂ (Schulze, *J. pr.* [2] 24, 168; Bineau, *A. Ch.* [3] 34, 326). μ_{Na} = 1·85 at 15° (Bleekrode, *Pr.* 87, 359). For surface tension of liquid SO₂ v. Clark (*C. N.* 88, 294; 40, 8). For absorption-spectrum v. Liveing a. Dewar (*C. N.* 47, 121).

Occurrence.—In volcanic gases, and in river and spring water near volcanoes (v. Ricciardi, *G.* 18, 38).

Formation.—1. By burning S in O. Baker (*Pr.* 45, 1; *C. J.* 47, 349) found that the combustion of S in O is retarded the drier the O is; using very carefully dried O there was no flame. According to Hempel (*B.* 23, 1456) c. 2 p.c. of the gas formed when S is burnt in O at the ordinary pressure is SO₃, 98 p.c. being SO₂; at a pressure of 40°–50° atmos. c. half the S is burnt to SO₃ and half to SO₂; at higher pressures c. 70 atmos. the proportion of SO₃ increases.—2. By heating S with oxide of Pb, Mn, Hg, Zn, &c.—3. By heating various sulphates with S, also SO₂ with S, or conc. H₂SO₄ with C, Cu, Hg, or S; by heating Na₂SO₄ with charcoal and SiO₂.—4. By the decomposition, by acids, of alkali thiosulphate or polythionate solutions.—5. By burning H₂S, CS₂, and various organic compounds containing S.—6. By decomposing conc. H₂SO₄ by heat.—7. By the action of electric sparks on a mixture of sulphur with CO₂, NO, or N₂O (Chevriér, *C. R.* 69, 136).

Preparation.—1. Pure H₂SO₄, mixed with half to two-fifths its volume of water, is heated with pure Cu; the SO₂ that comes off is passed through water in a large flask, and then through a couple of bottles filled with pumice, broken into small pieces and moistened; the pumice should be twice moistened with pure H₂SO₄, and heated to redness before being used, to remove chlorides and fluorides (Stas, *Chem. Propert.* 115). The SO₂ may be dried by passing it through pure conc. H₂SO₄, and then over CaCl₂.—2. A mixture of 3 parts pure CuO and 1 part S in powder is heated in a tube of hard glass; the anterior part of the tube contains CuO only, to oxidise S that may sublime (Marchand, *P.* 42, 144).—3. Neumann (*B.* 20, 1584) obtains a regular stream of approximately pure SO₂ by placing a mixture of three parts CaSO₃ and 1 part CaSO₄, made into small cubes, in a Kipp's apparatus, and decomposing by ordinary oil of vitriol. The acid should be allowed to come into contact with sufficient cubes, and no more, to give the stream of gas that is required. Using c. 500 g. of the cubes, N. obtained a constant stream of SO₂ for 30 hours. The cubes are made by mixing the CaSO₃ and CaSO₄, moistening with water so that a semi-solid mass is obtained that can be worked with the fingers with some difficulty, pressing this in an iron mortar, hammering it into an iron frame c. 10–12 mm. in height, covering with oilcloth and pressing strongly, cutting into cubes while still in the frame, removing and drying at c. 20° (v. Winkler, *B.* 20, 184).

Properties.—A colourless gas, at ordinary temperatures and pressures, with the strong penetrating, choking odour of burning S; causes coughing and blood-spitting if inhaled in any quantity. Incombustible in air, and extinguishes flame; when mixed with O and passed over heated spongy Pt it is oxidised to SO₃. Dry SO₂ is said not to redden litmus paper (Wilson, *C. J.* 1, 332). Bleaches many vegetable colours; the colours are generally restored by alkalis. Bad conductor of electricity (v. Bleekrode, *P. M.* [5] 5, 375, 439). Is not decomposed by passing through a red-hot tube. Condensed at c. –10° under the ordinary pressure—by passing the dry gas into a tube surrounded by a mixture of snow and salt; may also be condensed at the ordinary temperature by evolving the gas (by warming charcoal saturated with SO₂, or a mixture of 1 part S and 5 parts SO₂) in one limb of a closed tube, the other limb being placed in cold water. Convenient apparatus for liquefying SO₂ is described by Wöhler (*A.* 137, 371) and Hofmann (*B.* 2, 262).

Liquid SO₂ is a colourless, mobile liquid. Exposed to air it evaporates very rapidly, with disappearance of much heat; an air thermometer placed in liquid SO₂ at 10°, in an open vessel, falls to –57°. Liquid SO₂ dissolves P, S, I, Br, and many gums. It is miscible in all proportions with liquid SO₃; partially miscible with CS₂, Et₂O, CHCl₃, and C₂H₆ on warming; but immiscible with conc. H₂SO₄ (Sestini, *B.* [2] 10, 226). Liquid SO₂ is a non-conductor of electricity (Magnus, *P.* 104, 533).

By evaporating liquid SO₂ rapidly in an air-pump, part of it solidifies to a white, woolly

mass; the liquid may also be solidified by placing it in a mixture of solid CO_2 and ether.

Reactions and Combinations.—1. SO_2 is not decomposed by passing through a red-hot tube. But by heating to $c. 1200^\circ$ it is changed to SO_3 and S ($3\text{SO}_2 = 2\text{SO}_3 + \text{S}$); the action stops when the SO_3 attains a certain vapour pressure, but if the SO_2 is removed (by conc. H_2SO_4) the whole of the SO_2 is decomposed (Deville, *C. R.* 60, 317). Induction sparks effect the decomposition of SO_2 to SO_3 and S (v. Buff a. Hofmann, *A.* 113, 129); light acts similarly (Morren, *C. R.* 69, 397).—2. H_2O and S are produced by passing SO_2 mixed with hydrogen through a red-hot tube.—3. Chlorine combines with SO_2 , in sunlight, to form SO_2Cl_2 (v. SULPHURYL CHLORIDE). SO_2Cl_2 is also formed by passing SO_2 and Cl into glacial acetic acid, even in the dark; also by passing SO_2 over charcoal saturated with Cl (Melsens, *C. R.* 76, 92).—4. Ozone produces SO_3 ; the same compound is formed by passing SO_2 mixed with oxygen over heated spongy Pt, or by burning SO_2 in O under a pressure of several atmos. (v. *supra*; *Formation*, No. 1). According to Berthelot (*A. Ch.* [5] 12, 463), S_2O_3 is formed by the action of the silent discharge on SO_2 mixed with oxygen. The compound $\text{S}_2\text{O}_3\text{N}_2$ is said to be formed by passing electric sparks through a mixture of SO_2 and air. This compound is probably $\text{S}_2\text{O}_3(\text{NO})_2$ (v. NITROSULPHONIC ANHYDRIDE, p. 601).—5. Passed over red-hot carbon the products are CO , CO_2 , and S ; COS and CS_2 are also sometimes formed, probably by secondary reactions (Scheurer-Kestner, *C. R.* 114, 296; cf. Berthelot, *Bl.* [2] 40, 362; Eilsart, *J.* 1885, 457).—6. Potassium burns when heated in SO_2 , giving K_2SO_3 , $\text{K}_2\text{S}_2\text{O}_3$, and polysulphides.—7. Many other metals, especially when in fine powder, burn in SO_2 ; Sb and Sn form oxides and sulphides; Fe , sulphide and sulphate; Pd and Pt , sulphides and SO_3 ; Au , S and SO_3 ; Mg , sulphate, sulphite, and sulphide; Al , Co , Ni , and Zn also burn; Bi and Hg do not react (Schiff, *A.* 67, 94; 117, 92; Uhl, *B.* 23, 2151).—8. Water dissolves SO_2 , forming $\text{H}_2\text{SO}_3\text{Aq}$ (v. SULPHUROUS ACID, p. 614). 9. Several metallic peroxides combine readily with SO_2 , forming sulphates; e.g. $\text{PbO}_2 + \text{SO}_2 = \text{PbSO}_4$; in this reaction much heat is produced.—10. Nitrogen dioxide is said to react with liquid SO_2 to form nitrosulphonic anhydride $\text{S}_2\text{O}_3(\text{NO})_2$ (v. p. 601). With nitric oxide or dioxide, in presence of water, nitrosulphonic acid $\text{NO}(\text{SO}_2\text{OH})$ (q. v., p. 601) is formed. Nitric oxide in presence of alkali produces salts of $\text{SO}_2\text{OH}(\text{NO})_2\text{H}$ (v. NITROSULPHATES, p. 581).—11. Selenion dioxide does not react with SO_2 (Schulze, *J. pr.* [2] 82, 390).—12. Dry hydrogen sulphide does not react; moist H_2S , at the ordinary temperature, produces $\text{H}_2\text{S}_2\text{O}_3$, S , and H_2O (Cluzel a. Schmid, *Chem. Zeitung*, 11, 50); there is said to be no reaction in presence of water above 400° (Mulder, *J.* 1858, 84).—13. Phosphoretted hydrogen reacts at the ordinary temperature to form H_2O and P_2S_3 (*C. a. S.*, l.c.).—14. Ammonia combines with SO_2 , probably producing SO_2NH_2 ($= \text{SO.OH.NH}_2$) and $\text{SO}_2.2\text{NH}_3$ ($= \text{SO.ONH}_2.\text{NH}_2$) (v. THIONAMIC ACID).—15. Hydrochloric or hydriodic acid produces H_2O , S , and Cl or I .—16. Many oxy-salts, e.g. nitrates and chlorates, react with

SO_2 , when heated, to form sulphates and N oxides; at higher temperatures SO_2 is sometimes produced (v. Hodgkinson a. Young, *C. N.* 66, 199).—17. Alkali nitrates yield salts of nitrosulphonic acid $\text{N}(\text{SO}_2\text{OH})_2$ (q. v., p. 601), and salts of oxy-imidosulphonic acid $\text{N}(\text{OH})(\text{SO}_2\text{OH})_2$ (q. v., p. 602).—18. Combines with aluminium chloride at 50° – 60° , forming $\text{AlCl}_3.\text{SO}_2$, which gives off SO_2 at a higher temperature (Adrianoffski, *B.* 12, 688).—19. Phosphorus pentachloride produces POCl_3 and SOCl_2 (Kremers, *A.* 70, 297; Schiff, *A.* 102, 111).

SULPHUR TRIOXIDE SO_3 . (*Sulphuric oxide. Sulphuric anhydride.*) Mol. w. 79.86. Melts at 14.8° (Weber, *B.* 19, 3189; Rebs, *A.* 246, 356). Some other observers have given m.p. as high as 29.5° (v. Buff, *A. Suppl.* 4, 129; Bussy, *A. Ch.* [2] 26, 411; Fischer, *P.* 16, 119; Marignac, *A.* 88, 230). Boils at 46.2° (Weber, l.c.; v. also Buff, l.c.; Fischer, l.c.; Schultz-Sellaack, *P.* 139, 480). S.G. 1.94 at 16° (Weber, l.c.); 1.97 at 20° (Bussy, l.c.); 1.9086 at 25° (Buff, l.c.). V.D. 39.78 (Schultz-Sellaack, *P.* 139, 480; Perman, *Pr.* 48, 45). H.F. $[\text{S.O}_3] = 103,240$ (liquid SO_3 from solid S ; *Th.* 2, 254); $[\text{SO}_3, \text{O}] = 32,160$ (liquid SO_3 from gaseous SO_2 ; *Th.*, l.c.); $[\text{SO}_3, \text{Aq}] = 39,170$ (liquid SO_3 ; *Th.*, l.c.). For heat of vaporisation v. Berthelot (*C. R.* 90, 1510). Schultz-Sellaack gives vapour-pressure at 20° as 152 mm. Hg (*P.* 139, 480).

Formation.—1. By the interaction of ozone and SO_2 . Also by the action of an induction current on a mixture of SO_2 and O (Buff a. Hofmann, *A.* 113, 129; Deville, *Bl.* [2] 3, 366); Berthelot (*C. R.* 86, 20) says that the product is S_2O_3 .—2. By burning S in O under a pressure of several atmos. (v. SULPHUR DIOXIDE, *Formation* No. 1). Also by heating pyrites (Scheurer-Kestner, *C. R.* 99, 917; Lunge, *B.* 10, 1824).—3. By passing a mixture of SO_2 and O over heated Pt (Phillips a. Magnus, *P.* 24, 610), spongy Pt (Hodgkinson a. Lowndes, *C. N.* 57, 193), or certain oxides, e.g. Fe_2O_3 , CuO , Cr_2O_3 (Mahla a. Wöhler, *A.* 81, 255).—4. By heating certain sulphates or bisulphates, e.g. $\text{Fe}_2(\text{SO}_4)_3$, $\text{Bi}_2(\text{SO}_4)_3$, Ag_2SO_4 , or NaHSO_4 .—5. By distilling Nordhausen sulphuric acid (v. Osann, *D. P. J.* 151, 158); also by heating conc. H_2SO_4 with P_2O_5 (Barreswil, *C. R.* 25, 30; Evans, *Ph.* 8, 127).

Preparation.—1. Fuming sulphuric acid is heated at as low a temperature as possible; the impure SO_3 is collected in a dry retort and redistilled once or twice, the most volatile portion being collected each time. The partially purified SO_3 is then distilled into a small tube, $c. 8$ – 10 mm. wide and about the length of a finger, containing some dry P_2O_5 ; this tube is narrowed at one end and fused on to a thick-walled tube $c. 1$ – 1.5 mm. wide, which is bent round and fused to a receiving tube $c. 12$ – 15 mm. wide and 800 mm. long; the tube containing the SO_3 and P_2O_5 is heated in a water-bath to 90° – 100° for 6 or 8 hours, the receiving tube projecting upwards, so that the distillate flows back again into the distilling-tube. The position of the apparatus is then changed, so that the receiving tube is lower than the distilling tube, and the SO_3 is distilled from the P_2O_5 on a water-bath. When sufficient SO_3 has been collected, the narrow connecting tube is fused off, and the SO_3 is kept in the sealed receiving tube (Weber, *B.* 19, 3189).—

2. A mixture of SO_2 and O , in the ratio $\text{SO}_2:\text{O}$, is passed over platinised asbestos heated nearly to redness; the SO_2 is condensed in a small dry tube, in which it is sealed up. The mixture of SO_2 and O is obtained by strongly heating conc. H_2SO_4 and removing H_2O ($\text{H}_2\text{SO}_4 = \text{H}_2\text{O} + \text{SO}_3 + \text{O}$) by cooling and passing through coke moistened with 60 p.c. H_2SO_4 (Winkler, *D. P. J.* 218, 128). The asbestos is platinised by soaking in PtCl_4 and made alkaline by soda, and mixed with sufficient HCO_2Na to reduce the Pt, drying at 100° , carefully washing out the salts with water, and drying (Thomsen, *B.* 3, 496). The SO_2 thus obtained is not quite pure. It may be purified by distillation with P_2O_5 (*v. supra*).

Properties.—A colourless, mobile liquid, solidifying at $c. 15^\circ$ to long, prismatic, transparent crystals, which melt at 14.8° . According to some observers (*v. Marignac, Ar. Ph.* 22, 225; 58, 228; Schultz-Sellack, *P.* 139, 480) the crystals of SO_2 slowly change to a mass of tough, opaque, lustrous needles, which melt above 50° , and constitute a distinct modification of SO_2 ; but the experiments of Weber (*P.* 139, 480; *B.* 19, 3187; *cf. Rebs, A.* 246, 356) have shown that pure SO_2 exists only in one form, and that the substance with higher m.p. is formed by the action of traces of H_2SO_4 in the SO_2 ; a small trace of moisture suffices to cause the gradual change. SO_2 is very acrid and poisonous; it chars paper, wood, and organic matter generally. SO_2 is extremely hygroscopic; it dissolves in water with a hissing sound and production of much heat ($[\text{SO}_2:\text{Aq}] = 39, 170$), forming $\text{H}_2\text{SO}_4\text{Aq}$. Non-conductor of electricity (Magnus, *P.* 104, 553); not decomposed by electric sparks, but by passing through a red-hot tube gives SO_2 and O . SO_2 does not redden dry litmus. It is a strongly acid-forming oxide (*v. SULPHURIC ACID*).

Reactions and Combinations.—1. Heated to redness (by passing through red-hot tube) gives $\text{SO}_2 + \text{O}$.—2. Not decomposed by electric sparks (Magnus, *P.* 104, 553); electrolysis of SO_2 in H_2SO_4 causes separation of S and O , and the solution becomes blue (Geuther, *A.* 109, 129).—3. Water reacts violently with SO_2 forming $\text{H}_2\text{SO}_4\text{Aq}$ (*v. SULPHURIC ACID*).—4. Hydrogen sulphide produces H_2SO_4 and S .—5. A mixture of SO_2 and oxygen, in the ratio $2\text{SO}_2:\text{O}$, forms S_2O_3 , when submitted to the silent electric discharge (Berthelot, *A. Ch.* [5] 14, 345).—6. Sulphur dissolves in SO_2 forming S_2O_3 ; selenium and tellurium react similarly (*v. SULPHUR THIO-OXIDE, SELENIUM THIO-OXIDE, and TELLURIUM THIO-OXIDE*).—7. Phosphorus ignites in vapour of SO_2 , forming P_2O_5 and S .—8. Iodine dissolves in SO_2 , apparently forming several compounds (*v. Wach, S.* 50, 37; Schultz-Sellack, *B.* 4, 109), Weber (*J. pr.* [2] 25, 224) describes the compounds $\text{I}(\text{SO}_2)_2$, $\text{I}(\text{SO}_2)$, and $\text{I}_2(\text{SO}_2)$.—9. Iron and zinc react at red heat to give sulphides and oxides; mercury produces sulphate and SO_2 (*d'Heureuse, P.* 75, 255).—10. Several metallic sulphides—e.g. of Sb , Pb , K —form sulphates and SO_2 , when heated with SO_2 (Weber, *P.* 139, 329).—11. Dry sulphur dioxide is absorbed by SO_2 at 0° , forming a thin, fuming liquid, approximately $\text{SO}_2.2\text{SO}_2$ (*H. Rose, P.* 39, 175). According to Schultz-Sellack, liquid SO_2 and SO_3 are miscible in all proportions (*P.* 139, 480).—12. Selenium dioxide combines to form $\text{SO}_2.\text{SeO}_2$

(*v. SELENIUM DIOXIDE, Combinations, No. 4, p. 441*).—13. Nitric oxide, in absence of moisture and O , forms $\text{S}_2\text{O}_3\text{N}_2$, which is generally called nitrosulphonic anhydride (*q. v.*, p. 601) and written $\text{S}_2\text{O}_3(\text{NO})_2$. Nitrogen dioxide (made by heating $\text{Pb}(\text{NO}_3)_2$) seems to form $\text{SO}_2.\text{NO}_2$, and on heating this and passing in more NO_2 , O is given off and the compound $\text{S}_2\text{O}_3\text{N}_2$ remains (*v. Weber, P.* 123, 337; Brüning, *A.* 98, 377). The formula of the first of these compounds is generally doubled, and the compound regarded as $\text{S}_2\text{O}_3.\text{O}(\text{NO})_2$ —oxynitrosulphonic anhydride (*q. v.*, p. 601); the second is described in some books as $\text{S}_2\text{O}_3(\text{NO})_2$ and is called nitrosyl pyrosulphate, but from the descriptions of Weber and Brüning it is evidently the same as the compound $\text{S}_2\text{O}_3\text{N}_2$ formed from NO and SO_2 , i.e. it is nitrosulphonic anhydride.—14. SO_2 combines with iodine pentoxide to form $8\text{SO}_2.\text{I}_2\text{O}_5$ and $\text{SO}_3.5\text{I}_2\text{O}_5$ (Weber, *B.* 20, 86; Kämmerer, *J. pr.* 83, 72). With phosphorus pentoxide $8\text{SO}_2.\text{P}_2\text{O}_5$, decomposing at 30° , is formed (Weber, *B.* 19, 3185; 20, 86). Arsenious oxide forms various unstable compounds (Adie, *C. J.* 55, 157; *cf. Weber, B.* 19, 3185; Schultz-Sellack, *B.* 4, 109; Reich, *J. pr.* 90, 176; Schaffhäutl, *B. J.* 22, 113; and Pearce, *Z. K.* 20, 632). According to Baker (*C. J. Proc.* 1893, 130), dry SO_2 does not react with dry oxides of barium, calcium, or copper.—15. The compound $\text{SO}_2.\text{N}_2\text{O}.5\text{H}_2\text{SO}_4$ is said to be formed by passing SO_2 into pure, well-cooled, nitric acid (Weber, *P.* 123, 233; 142, 602).—16. Boric acid forms $\text{BH}_3\text{O}_3.3\text{SO}_2$ [$=\text{B}(\text{HSO}_3)_3$] (*D'Arcy, C. J.* 55, 155; *cf. Merz, J. pr.* 99, 81; Schultz-Sellack, *B.* 4, 15).—17. Hydrobromic and hydriodic acids separate Br and I , and form H_2SO_4 and SO_2 .—18. Hydrochloric and hydrofluoric acids form $\text{Cl}(\text{SO}_2.\text{OH})$ and $\text{F}(\text{SO}_2.\text{OH})$ (*v. CHLOROSULPHONIC ACID, p. 599; and FLUOSULPHONIC ACID, p. 600*).—19. Conc. sulphuric acid forms $\text{H}_2\text{S}_2\text{O}_7$ (*v. PYROSULPHURIC ACID, p. 625*).—20. Ammonia produces $\text{NH}_4(\text{SO}_3.\text{OH})$ and salts of this acid (*v. SULPHAMIC ACID AND SALTS, p. 567*); and also salts of $\text{NH}(\text{SO}_3.\text{OH})_2$ (*v. IMIDOSULPHONIC ACID AND SALTS, p. 600*).—21. Phosphoretted hydrogen produces SO_2 and red P (*H. Rose, P.* 24, 140; Aimé, *J. pr.* 6, 79).—22. Phosphorus trichloride reacts violently, forming POCl_3 and SO_2 (*Armstrong, B.* 3, 732; Michaelis, *J. Z.* 6, 239). Phosphorus pentachloride produces pyrosulphuryl chloride $\text{S}_2\text{O}_3\text{Cl}_2$ (*q. v.* under SULPHUR OXYCHLORIDES, p. 617).—23. Boron chloride reacts at $c. 120^\circ$ to form $\text{S}_2\text{O}_3\text{Cl}_2$ (*Prudhomme, Bl.* [2] 14, 385).—24. Nitrosyl chloride (produced by heating aqua regia) produces $\text{SO}_2.\text{NOCl}$ [$=\text{NO}_2(\text{SO}_2.\text{Cl})$] (*v. NITROSULPHONIC CHLORIDE, p. 601*).—25. Pyrosulphuryl bromide $\text{S}_2\text{O}_3\text{Br}_2$ (*q. v.*, p. 617) is perhaps formed by the reaction of bromoform with SO_2 .—26. Selenium tetrachloride produces SSeO_3Cl_4 (*v. SELENIUM THIO-OXYCHLORIDES, p. 441*).

SULPHUR PEROXIDE S_2O_8 . (Sulphur heptoxide. Persulphuric anhydride.) Mol. *w.* not known with certainty but probably 175.68 (S_2O_8). This oxide was prepared by Berthelot in 1877 (*A. Ch.* [5] 14, 345) by passing the 'silent' electric discharge, for several hours, through a mixture of SO_2 and O in the ratio $2\text{SO}_2:\text{O}$, or of SO_2 and O in the ratio $2\text{SO}_2:3\text{O}$. (For apparatus used *v. B., A. Ch.* [5] 12, 463.) Oily drops

formed on the sides of the tube, and on reducing the temperature nearly to 0° they solidified to long, white, crystalline, needles. S_2O_2 resembles solid SO_2 in appearance; it remains unchanged in a sealed tube for some days at 0° ; when heated it gives SO_2 and O ; dissolves in conc. H_2SO_4 forming a fairly stable solution; fumes in the air; in water it rapidly decomposes forming H_2SO_4 and giving off a brisk stream of O ; with BaO forms $BaSO_4$ and O ; and also some Ba persulphate, according to Berthelot (*l.c.*; no analyses given). By electrolysis H_2SO_4 containing water and acid in the ratio $10H_2O:H_2SO_4$, B. (*C. R.* 90, 269) obtained a quantity of persulphuric acid ($H_2S_2O_8$); v. under SULPHURIC ACID, p. 625 equal to from 88 to 123 g. S_2O_8 per litre; using an acid of the concentration $H_2SO_4:2H_2O$ to $H_2SO_4:3H_2O$, B. (*l.c.*) says that a compound $S_2O_8 \cdot 2H_2O_2$ is formed, which is decomposed by excess of conc. H_2SO_4 chiefly to $H_2S_2O_8$, and by dilution with water to $H_2S_2O_8$ and H_2O_2 which after a time decompose to H_2SO_4 , H_2O , and O .

S_2O_8 is the anhydride of persulphuric acid $H_2S_2O_8$ (*q. v.*, p. 625). Mendeléeff (*B.* 15, 242) regards S_2O_8 as analogous in constitution to

H_2O_2 , and writes the formula $\begin{array}{c} \text{OSO} \\ \diagup \quad \diagdown \\ \text{OSO}_2 \end{array} \text{O}$; he

looks on the corresponding acid as derived from H_2O_2 by replacing $2H$ by $2SO_3OH$, thus: $O.(SO_3OH)$.

$O.(SO_3OH)$. According to Traube (*B.* 22, 1518; 24, 1764; 25, 95), the liquid obtained by electrolysis 40 p.c. H_2SO_4 contains an oxide to which he gives the formula SO_4 and calls *sulphuryl hyperoxide* (or *holoxide*), SO_3O_2 . Traube did not isolate this compound; his argument for its existence is based on the results of indirect analyses. In the light of the criticisms of Carnegie (*C. N.* 64, 158) it may be concluded that the existence of SO_4 is extremely improbable. In a later communication (*B.* 26, 1481) Traube thinks it is probable that SO_4 does not exist.

Sulphur, oxyacids of. For compositions of these acids, and references to articles where they are described, v. SULPHUR, OXYACIDS OF (p. 619).

Sulphur, oxyacids of, nitrogen derivatives of. For a general statement regarding these compounds, and references to the articles where they are described, v. SULPHUR OXYACIDS, NITROGEN DERIVATIVES OF (p. 619).

Sulphur, oxybromides of. There is very little definite knowledge regarding the compounds of S , O , and Br . According to Michaelis (*J. Z.* 6, 239, 296) PBr_3 does not react with SO_2 , and a mixture of PCl_3 and Br (in the ratio $PCl_3:Br$) produces $POCl_3$ and S bromides. Rose (*P.* 44, 827) and Clausnizer (*B.* 11, 2019) could not obtain an oxybromide by the reaction of SO_2 and S bromide, nor by the action of SO_2 and HBr .

In his memoir on $S_2O_2Cl_2$ prepared by the reaction of SO_2 with $CHCl_3$, Armstrong (*B.* 2, 712) states that $CHBr_3$ reacts with SO_2 similarly to $CHCl_3$, but he does not describe the product. If the reaction of $CHBr_3$ with SO_2 is strictly similar

to that of $CHCl_3$, the product would be *pyrosulphuryl bromide* $S_2O_2Br_2$.

Odling (*C. J.* 7, 2) supposed that *sulphuryl oxy-bromide* SO_2Br_2 was formed by the action of sunlight on SO_2 and Br , but Sestini (*Bl.* [2] 10, 226) and Melsens (*C. R.* 76, 92) failed to obtain an oxybromide by this method.

TRIONYL BROMIDE $SOBr_2$. This compound was obtained, but not quite free from S bromides, by Hartog a. Sims (*C. J. Proc.* No. 118, 1898, 10) by the interaction of $SOCl_2$ and $NaBr$; it is described as a very hygroscopic, crimson liquid, S.G. 2.68 at 18° , decomposing at 150° to Br , S bromides, &c.

Sulphur, oxychlorides of. Five compounds have been isolated, $SOCl_2$, SO_2Cl_2 , $S_2O_2Cl_2$, S_2OCl_2 , and $S_2O_3Cl_2$.

TRIONYL CHLORIDE $SOCl_2$ (Sulphurous oxy-chloride). Mol. w. 118.62. Boils at 78.8° ; S.G. 1.67678 , S.G. at b.p. 1.52143 (Thorpe, *C. J.* 37, 354; for other data v. Carius, *A.* 106, 303; 111, 98; Wurtz, *C. R.* 62, 460). V.D. at c. $150^{\circ}=56$, at c. $440^{\circ}=39$ (Heumann a. Köchlin, *B.* 16, 1625). H.F. $[S_2O_2Cl_2]=40.800$; heat of vaporisation = 6,480 (Ogier, *C. R.* 94, 82). S.V. 78.01 (Thorpe, *l.c.*).

Formation.—1. By the reaction of PCl_3 with SO_2 (Kremers, *A.* 70, 297; Schiff, *A.* 102, 111), $SOCl_2$, $C_2H_5SO_2Cl$, and several other organic compounds containing S (v. Kekulé a. Barbaglia, *B.* 5, 875; Carius, *J. pr.* [2] 2, 262), sulphites, or thiosulphates; also by the reaction of $POCl_3$ with sulphates.—2. By the action of Cl_2O on CS_2 , or on S in S_2Cl_2 at -12° (Wurtz, *C. R.* 62, 460).—3. By the interaction of SO_2 and $SOCl_2$ (Michaelis a. Schifferdecker, *B.* 5, 924; 6, 993).—4. Along with SO_2Cl_2 by the gradual decomposition of $S_2O_3Cl_2$ (*q. v.*, p. 619).

Preparation.—1. About 100 g. dry PCl_3 are placed in a retort connected with a reversed condenser, and a stream of dry SO_2 is led in till the PCl_3 has liquefied; another 100 g. PCl_3 is added and the stream of SO_2 is continued; when sufficient PCl_3 has thus been decomposed ($PCl_3 + SO_2 = SOCl_2 + POCl_3$) the liquid is heated for some time (the reversed condenser being still attached) to get rid of SO_2 , and then fractionated repeatedly ($SOCl_2$ boils at 78.8° and $POCl_3$ at 107.2°) (Carius, *A.* 106, 303; 111, 98; Wurtz, *A.* 189, 375; Michaelis, *A.* 170, 1; Thorpe, *C. J.* 37, 354).—2. S_2Cl_2 is placed in a small flask, cooled to c. -20° , a stream of dry Cl_2 is led in till the liquid is saturated, and then SO_2 is distilled into the flask from a solution in conc. H_2SO_4 ; the weights of S_2Cl_2 and SO_2 used should be in the ratio $S_2Cl_2:4SO_2$ (= 1:2.37); convenient quantities to use are 22 g. S_2Cl_2 and 50 g. SO_2 ($S_2Cl_2 + 2SO_2 = SOCl_2 + S_2O_3Cl_2$). The liquid is fractionated finally from a small quantity of SO_2 (Michaelis a. Schifferdecker, *B.* 5, 924; 6, 993).

Properties.—A colourless, very refractive liquid, fuming in the air, with a very penetrating odour; vapour attacks the eyes and respiratory organs. V.D. 56 at c. 150° , but 39 at c. 440° ; the smaller value corresponds with the decomposition $4SOCl_2 = S_2Cl_2 + 2SO_2 + 8Cl_2$; these products are obtained by passing vapour of $SOCl_2$ through a red-hot tube (Heumann a. Köchlin, *B.* 16, 1625).

Reactions and Combinations.—1. Moist air produces HCl and SO₂.—2. Water also forms HClAq and SO₂, warm water forming in addition H₂SO₄Aq and S (Carius, *l.c.*).—3. Hydrogen sulphide produces SO₂, HCl, and S (Prinz, *A.* 225, 371).—4. Phosphorus pentasulphide reacts to form SO₂, PSCl₃, and S, and some S₂Cl₂ (Prinz, *l.c.*).—5. With antimony trisulphide the products are SbCl₃, SO₂, and S.—6. Sulphur, heated to 180° with SOCl₂, forms S₂Cl₂ and SO₂; selenium forms S₂Cl₂ and SSeCl₂ (Prinz, *l.c.*).—7. Powdered antimony reacts without heating, forming SbCl₃, Sb₂S₃, and SO₂.—8. POCl₃, PSCl₃, and PCl₅ are formed by heating SOCl₂ with phosphorus trichloride (Michaelis, *J. Z.* 6, 239).—9. Heating with sulphur dichloride produces S₂OCl₂ (*q. v.*, p. 619) (Ogier, *Bl.* [2] 37, 293).—10. Ammonia does not produce thionylamide SO(NH₂)₂, but forms NS, NH₄Cl, (NH₄)₂SO₄, and NH₄ polythionates (M., *l.c.*).—11. Reacts rapidly with silver nitrate, forming NO₂(SO₂Cl) (Thorpe, *C. J.* 41, 297).—12. SOCl₂ absorbs sulphur dioxide and chlorine freely (M., *l.c.*).—13. For reactions with various organic compounds *v.* Michaelis (*l.c.*); Heumann a. Köchlin (*B.* 16, 1625); Böttinger (*B.* 11, 1407).

SULPHURYL CHLORIDE SO₂Cl₂ (*Sulphuric oxychloride*). Mol. w. 134.58. Boils at 69.95° (Thorpe, *C. J.* 37, 359; for other determinations *v.* Regnault, *J. pr.* 19, 243; Clausnizer, *B.* 11, 2010; Ogier, *C. R.* 94, 82). S.G.₄²⁰ 1.70814; at b.p. 1.56025 (Thorpe, *l.c.*). V.D. 65 at 184°; 34 at 440° (Heumann a. Köchlin, *B.* 16, 602; *cf.* Regnault, *J. pr.* 18, 97; Behrend, *J. pr.* [2] 15, 23). S.V. 86.29 (Thorpe, *l.c.*, p. 372). H.F. [S₂O₂Cl₂] = 89,780; [SO₂Cl₂] = 18,700 (*Th.* 2, 310; *cf.* Ogier, *C. R.* 94, 82). S.H. (15°–63°) .233 (Ogier, *l.c.*). Heat of vaporisation 7,060 (O., *l.c.*).

Formation.—1. By the direct combination of SO₂ and Cl in sunlight, or by reacting on a mixture of C₂H₄ and SO₂ by Cl in sunlight (Regnault, *J. pr.* 18, 93; 19, 243). Schulze (*J. pr.* [2] 23, 351; 24, 168) recommends to allow SO₂ and Cl to react in presence of camphor. Melsens (*C. R.* 76, 92) passes SO₂ and Cl into glacial acetic acid.—2. By passing SO₂ over charcoal saturated with Cl (M., *l.c.*).—3. By the interaction of PCl₅ with H₂SO₄ or SO₃ (Williamson, *P. M.* [4] 7, 365; Schiff, *A.* 102, 111); according to Michaelis (*J. Z.* 6, 233, 292), SO₂ and PCl₅ form S₂O₂Cl₂.—4. By heating SO₂ and BCl₃ in the ratio 2SO₂:BCl₃ to 120° in a closed tube (Gustavson, *B.* 6, 9).—5. By heating Cl(SO₂OH) to c. 200° for some time (Behrend, *B.* 8, 1004; *cf.* Otto a. Beckurts, *B.* 11, 2058).

Preparation.—1. Cl and SO₂ are passed into camphor, and the colourless liquid is fractionated (Schulze, *l.c.*).—2. Cl(SO₂OH) (*v.* CHLOROSULPHONIC ACID, p. 509) is heated to c. 200°, in a closed tube, for some hours, when it decomposes thus, 2Cl(SO₂OH) = SO₂Cl₂ + H₂SO₄; the liquid is distilled, the portion coming over at 67°–71° being collected separately and then repeatedly fractionated (Behrend, *l.c.*; *cf.* Thorpe, *l.c.*).

Properties and Reactions.—A colourless liquid, fuming slightly in air. 1. Decomposed by heating to dull redness into SO₂ and Cl; decomposition is complete at 440° (Heumann a. Köchlin, *B.* 16, 602); but does not begin at 250°

(Beckurts a. Otto, *B.* 11, 2060).—2. Water produces HClAq and H₂SO₄Aq; a small quantity of water is said to form Cl(SO₂OH)Aq.—3. Excess of SO₂Cl₂ added to a little alcohol forms Cl(SO₂OE_t); with excess of alcohol SO₂(OE_t)₂ is produced (Behrend, *B.* 9, 1384).—4. Phosphorus pentachloride reacts to form POCl₃, SOCl₂, and Cl (H. a. K., *B.* 15, 1736).—5. Phosphorus, arsenic, and antimony produce PCl₃, AsCl₃, and SbCl₃ respectively, and SO₂ (H. a. K., *l.c.*).—6. Ammonia forms NH₄Cl and SO₂.NH₄.ONH₂.—7. With many organic compounds SO₂Cl₂ reacts like PCl₅ or POCl₃, substituting Cl for H (*v.* Dubois, *Z.* [2] 2, 705; Michaelis, *A.* 170, 1).

PYROSULPHURYL CHLORIDE S₂O₂Cl₂ = Cl.SO₂.O.SO₂.Cl. (*Disulphuryl chloride*. *Pyrosulphuric oxychloride*. *Chlorosulphonic anhydride*.) Mol. w. 214.38. Boils at 139.59° (Thorpe, *C. J.* 37, 360; for other determinations *v.* Rose, *P.* 44, 291; Michaelis, *J. Z.* 6, 235, 240, 292; Rosenstiehl, *C. R.* 53, 658; Schützenberger, *C. R.* 69, 352). S.G.₂₀²⁰ 1.85846, at b.p. 1.60610 (Thorpe, *l.c.*). V.D. at slightly above b.p. = 104; between 160° and 240° = 54.8 (Heumann a. Köchlin, *B.* 16, 479; Kanowloff, *B.* 16, 1127; *cf.* Rosenstiehl, *C. R.* 53, 658; Rose, *P.* 44, 291; Ogier, *C. R.* 94, 82, 217; 96, 648). H.F. [S₂O₂Cl₂] = 180,600 (Kanowloff, *l.c.*); Ogier (*l.c.*) gives 159,400. Heat of vaporisation 7,570 (K.; *l.c.*); 13,160 (O., *l.c.*). S.H. .258 (K., *l.c.*).

Formation.—1. By the interaction of PCl₅ and SO₂ or Cl(SO₂OH).—2. By heating P₂O₅ and Cl(SO₂OH) (Billitz a. Heumann, *B.* 16, 483).—3. By heating SO₂ with NaCl (R., *l.c.*), with S₂Cl₂ (Rose, *P.* 44, 291), with CCl₄ (Schützenberger, *C. R.* 69, 352; Kanowloff, *C. R.* 95, 1284), with C₂Cl₆ (Prudhomme, *C. R.* 70, 1137), with CHCl₃ (Armstrong, *C. J.* [2] 1, 244), or with SiCl₄ (Gustavson, *B.* 5, 332).—4. By the interaction of POCl₃ and SOCl₂ (Michaelis, *J. Z.* 6, 235, 240, 292).

Preparation.—1. P₂O₅ and Cl(SO₂OH) are heated in a flask with a reversed condenser, using rather more Cl(SO₂OH) than P₂O₅; when HCl and SO₂ cease to be given off, the liquid is distilled, and the portion coming over between 135° and 145° is fractionated (B. a. H., *l.c.*).—2. S₂Cl₂ in a flask is surrounded by a freezing mixture, and saturated with SO₂; the product is fractionated; 5SO₂ + S₂Cl₂ = 5SO₂ + S₂O₂Cl₂ (Rose, *P.* 44, 291). Thorpe (*C. J.* 37, 360) found that the product of this reaction boiled almost wholly between 135° and 138°.

Properties and Reactions.—A colourless, mobile, very refractive liquid, fuming in the air with formation of Cl(SO₂OH).—1. Decomposed by heat to SO₂, SO₃, and Cl (Rose, *P.* 44, 291); the V.D. determinations of Heumann a. Köchlin (*B.* 16, 479) show that at 440° the decomposition is S₂O₂Cl₂ = SO₂ + SO₃ + Cl₂.—2. Sinks in water, and is slowly decomposed to HClAq and H₂SO₄Aq; if a very little water is used Cl(SO₂OH) is formed, thus S₂O₂Cl₂ + H₂O = 2Cl(SO₂OH) (*v.* B. a. H., *l.c.*).—3. Reacts with phosphorus, sulphur, antimony, copper, iron, zinc, and some other metals, to produce chlorides, SO₂ and SO₃ (Heumann a. Köchlin, *B.* 16, 479).—4. Phosphorus trichloride produces

POCl_3 , POCl_2 , and SO_2 ; *phosphorus pentachloride* forms POCl_2 , Cl , and SO_2 (Geuther, *B.* 5, 925). 5. *Selenion tetrachloride* gives SSeO_2Cl_2 (Clausnizer, *B.* 11, 2010).—6. *Chromates* react to form CrO_2Cl_2 (Rosenstiehl, *C. R.* 53, 658).—7. *Ammonia* forms a white solid, which dissolves in water, producing NH_4Cl and a sulphamate of NH_4 (Rose, *l.c.*).

SULPHUR MONOXYTETRACHLORIDE S_2OCl_4 . By heating equal weights of S_2Cl_2 and SO_2Cl_2 to 250° in a sealed tube, Ogier (*Bl.* [2] 37, 293) obtained a deep-red liquid resembling S_2Cl_2 , S.G. 1.656 at 0° , decomposing under 100° to S_2Cl_2 , SO_2 , and S , to which he gave the composition S_2OCl_4 . Decomposed by water to $\text{H}_2\text{SO}_4\text{Aq}$, SO_2Aq , HClAq , thionio acids, and S .

SULPHUR TRI-OXYTETRACHLORIDE $\text{S}_2\text{O}_3\text{Cl}_4$. Mol. w. not determined. This compound was obtained by Millon (*A. Ch.* [3] 29, 327) by the action of moist Cl on S_2Cl_2 (*cf.* Marchand, *J. pr.* 22, 507; Carius, *A.* 106, 295). It is conveniently prepared by the reaction $\text{SCL}_4 + \text{Cl}(\text{SO}_2\text{OH}) = \text{HCl} + \text{S}_2\text{O}_3\text{Cl}_4$; a stream of dry Cl is led into a mixture, in the ratio of equal numbers of molecules, of S_2Cl_2 and $\text{Cl}(\text{SO}_2\text{OH})$, kept at *c.* -20° , until a semi-solid mass is obtained (a very wide tube must be used to lead in Cl); the temperature is then kept at *c.* -18° and the Cl is continued till the mass gets quite solid; the freezing mixture is then removed, and the Cl is continued till the mass is white, when the excess of Cl is removed by a stream of dry CO_2 (Michaelis a. Schifferdecker, *B.* 6, 996).

$\text{S}_2\text{O}_3\text{Cl}_4$ is a white, crystalline solid, with a most disagreeable odour; the vapour acts on the eyes. Melts at 57° , giving off SO_2 and Cl , and leaving a liquid that solidifies chiefly to SOCl_2 and $\text{S}_2\text{O}_3\text{Cl}_2$; a portion sublimes in fine white needles. Ice-cold water produces SO_2Aq , $\text{H}_2\text{SO}_4\text{Aq}$, and HClAq ; water at the ordinary temperature also separates S . Deliquesces in a partially closed vessel, giving off HCl , Cl , and SO_2 , and leaving a liquid that gives SOCl_2 and $\text{S}_2\text{O}_3\text{Cl}_2$ on distillation. Conc. H_2SO_4 reacts violently, forming HCl , SO_2 , and $\text{Cl}(\text{SO}_2\text{OH})$; CS_2 produces very rapid decomposition to COCl_2 , CO , SO_2 , S_2Cl_2 , and SOCl_2 . On long standing in a closed tube $\text{S}_2\text{O}_3\text{Cl}_4$ separates into equal numbers of molecules of SOCl_2 and SO_2Cl_2 (M. a. Mathias, *B.* 6, 1452).

SULPHUR, OXYACIDS OF. M. M. P. M. Several acids have been isolated, and salts of some others are known. The following list gives the names and compositions of the oxyacids of sulphur and their salts, with references to the articles where these compounds are described:—

HYPOSULPHUROUS ACID AND SALTS $\text{H}_2\text{S}_2\text{O}_3$ and $\text{M}_2\text{S}_2\text{O}_3$; *v. Hyposulphurous acid* under **SULPHUROUS ACID** (p. 627), and *hyposulphites* under **SULPHITES** (p. 592).

SULPHUROUS ACID AND SALTS H_2SO_3 , MHSO_3 , and M_2SO_3 ; *v. SULPHUROUS ACID* (p. 626), and **SULPHITES** (p. 587).

SULPHURIC ACID AND SALTS H_2SO_4 , MHSO_4 , and M_2SO_4 ; *v. SULPHURIC ACID* (p. 620) and **SULPHATES** (p. 567).

THIOSULPHURIC ACID AND SALTS $\text{H}_2\text{S}_2\text{O}_3$, MHS_2O_3 , and $\text{M}_2\text{S}_2\text{O}_3$; *v. THIOSULPHURIC ACID* (p. 708) and **THIOSULPHATES** (p. 705).

THIONIC ACIDS AND SALTS $\text{H}_2\text{S}_2\text{O}_4$, $\text{H}_2\text{S}_3\text{O}_6$, $\text{H}_2\text{S}_4\text{O}_8$, $\text{H}_2\text{S}_5\text{O}_{10}$, $\text{H}_2\text{S}_6\text{O}_{12}$ (and salts); *v. THIONIC ACIDS* (p. 698) and **THIONATES** (p. 695).

PYROSULPHURIC ACID AND SALTS $\text{H}_2\text{S}_2\text{O}_7$, MHS_2O_7 , and $\text{M}_2\text{S}_2\text{O}_7$; *v. Pyrosulphuric acid* under **SULPHURIC ACID** (p. 625), and *Pyrosulphates* under **SULPHATES** (p. 588).

PERSULPHURIC ACID AND SALTS $\text{H}_2\text{S}_2\text{O}_8\text{Aq}$, $\text{M}_2\text{S}_2\text{O}_8$, and MS_2O_8 ; *v. Persulphuric acid* under **SULPHURIC ACID** (p. 625), and *Persulphates* under **SULPHATES** (p. 582).

M. M. P. M.

SULPHUR OXYACIDS, NITROGEN DERIVATIVES OF. In 1845 Fremy (*A. Ch.* [3] 15, 408) described the K salts of a number of acids obtained by the interaction of KNO_3Aq and $\text{K}_2\text{SO}_4\text{Aq}$, and by boiling the products of this interaction with slightly acidified water; he called the compounds *salts of sulphazotised acids*. The examination of these salts was prosecuted by Claus a. Kooh (*A.* 152, 336 [1874], and by Claus (*A.* 158, 52, 194 [1876]); Berglund (*Bl.* [2] 25, 455; *B.* 9, 252, 1896 [1875]); and Raschig (*A.* 241, 161; *B.* 20, 584 [1887]) also investigated the sulphazotised acids of Fremy; and the researches of Divers and Haga (*C. J. Trans.* 1885, 1886, 1889, 1892) have thrown much light on many classes of these compounds. The more recent investigations noted above have shown many of the formulæ given by Fremy to be inaccurate, and they have also led to a considerable revision of Claus's results. As the compounds that have been fairly thoroughly examined are noticed under the heading **SULPHONIC ACIDS AND DERIVATIVES** (p. 509), it does not seem necessary to give an account of the other *salts of sulphazotised acids*, especially as it is very probable that the formulæ assigned to these compounds will require modification, and that some of the compounds will be found not to exist.

The chief *sulphazotised compounds* that have been investigated sufficiently to establish their composition satisfactorily are the following:—

Amidosulphonic acid and salts $\text{NH}_2(\text{SO}_3\text{OH})$; described as **SULPHAMIC ACID** (p. 567).

Imidosulphonic acid and salts $\text{NH}(\text{SO}_3\text{OH})_2$ (p. 600).

Nitrosulphonates $\text{N}(\text{SO}_3\text{OM})_2$ (p. 601).

Nitrosulphonic acid and salts $\text{NO}_2(\text{SO}_3\text{OH})$ (p. 601).

Nitrosulphonic anhydride $(\text{NO}_2)_2\text{S}_2\text{O}_3$ (p. 601).

Nitrosulphonic chloride $\text{NO}_2(\text{SO}_2\text{Cl})$ (p. 601).

Nitroso-oxy-amidosulphonates

$\text{N}(\text{NO.OH})(\text{SO}_3\text{OM})$; described as *nitroso-sulphates* under **SULPHATES** (p. 581).

Oxy-amidosulphonic acid and salts (and salts derived therefrom) $\text{NH}(\text{OH})(\text{SO}_3\text{OH})$ (p. 602).

Oxy-imidosulphonates (and salts derived therefrom) $\text{N}(\text{OH})(\text{SO}_3\text{OM})_2$ (p. 602).

Oxy-nitrosulphonic anhydride $(\text{NO}_2)_2\text{O.S}_2\text{O}_3$ (p. 601).

Sulphamide $(\text{NH}_2)_2\text{SO}_2$ (p. 567).

Sulphimide NH.SO_2 (p. 587).

Sulphimido-amide $\text{NH}(\text{SO}_2\text{NH}_2)_2$ (p. 587).

Thionamic acid and salts $\text{NH}_2(\text{SO}_2\text{OH})$ (p. 695). M. M. P. M.

SULPHURETTED HYDROGEN v. **HYDROGEN SULPHIDE**, vol. ii. p. 725.

SULPHURIC ACID; also **PERSULPHURIC ACID** and **PYROSULPHURIC ACID**.

SULPHURIC ACID H_2SO_4 (*Oil of vitriol*). Mol. w. probably 97.76. Melts at 10.35° (Pickering, *C. J.* 57, 831); 10.5° (Thilo, *Chem. Zeitung*, 16, 1688). Boiling begins at c. 290° , SO_2 and H_2O with some $\text{H}_2\text{SO}_4 \cdot x\text{H}_2\text{O}$ passing off; b.p. rises till 338° is reached, when it becomes constant and complete dissociation to SO_2 and H_2O occurs; for b.p. of $\text{H}_2\text{SO}_4\text{Aq}$ from 95 to 5 p.c. H_2SO_4 v. Lunge (*B.* 11, 870). S.G. $\frac{15^\circ}{15^\circ}$ 1.8984 (Perkin, *C. J.* 63, 59; cf. Pickering, *C. J.* 57, 73, note; Kohlrausch, *W.* 17, 69; Schertel, *J. pr.* [2] 26, 246; Mendeleeff, *B.* 17, 30, 2586; Lunge a. Isler, *Zeit. für anorg. Chemie*, 1890, 129). V.D. 25 at 440° , corresponding with dissociation to $\text{SO}_2 + \text{H}_2\text{O}$ (Deville a. Troost, *C. R.* 56, 891; Wanklyn a. Robinson, *Pr.* 12, 507). S.H. (22° to 80°) .355; (22° to 170°) .37 (Pfandler, *B.* 3, 798); (16° to 20°) .3315 (Marignac, *Ar. Sc.* 39, 217, 273). C.E. .0005585 at 20° (Marignac, l.c.). H.F. $[\text{H}_2^+\text{S}_2\text{O}_8^-] = 192,920$; $[\text{H}^+\text{O}, \text{SO}_4^-] = 21,320$ (formation of liquid H_2SO_4) (*Th.* 2, 255). Heat of fusion = 860 g. units (for 98 g. H_2SO_4) (Berthelot, *C. R.* 78, 716). T. C. v. Beetz (*W.* 7, 435), Weber (*J.* 1885, 121). $\frac{\mu-1}{d}$. Mol. w. = 32.45 (Gladstone, *P. M.* [4] 86, 311). For further data v. *infra*.

Occurrence.—Small quantities of H_2SO_4 , from .1 to .5 p.c., are found in some rivers and springs in volcanic districts; in a pool in Texas, Mallet (*C. N.* 26, 147) found 5.29 g. H_2SO_4 per litre of water. The acid is also found in certain animal secretions; the salivary glands of some molluscs are said to contain c. 2 p.c. (Bödeker a. Troschel, *B. B.* 1854, 486; De Luca a. Panceri, *Bl.* [2] 9, 400; Maly, *M.* 1, 205). The salts of sulphuric acid occur in large quantities (v. **SULPHATES**, p. 567).

Formation.—The formation of an oily liquid by heating alum is spoken of by Geber in the eighth century; a similar liquid was formed in the fifteenth century by burning sulphur with saltpetre. These liquids were shown to be identical towards the end of the sixteenth century. Oil of vitriol seems to have been manufactured in fair quantities by heating ferrous sulphate from about the early part of the eighteenth century; the first manufactory for making the acid from sulphur was started at Richmond by Ward about 1740. The composition of sulphuric acid was determined by Lavoisier.

1. By long exposure of flowers of sulphur in the air (John, *S.* 14, 417; Wagenmann, *P.* 24, 601).—2. By heating S with H_2O to c. 200° ; by electrolysis H_2O , using Pt electrodes with pieces of S attached, the H_2SO_4 forms at the positive pole (Bequerel, *C. R.* 56, 237).—3. By the oxidation of S in presence of H_2O by Cl_2 , HNO_3 , HCl and KClO_4 , *aqua regia*, &c.; also by certain metallic salts (v. Wicke, *A.* 82, 146; Parkmann, *Am. S.* [2] 88, 828).—4. By oxidising SO_2Aq or SO_2 in presence of water, by Cl_2 , Br , $\text{H}_2\text{O}_2\text{Aq}$,

NO_2 , HNO_3 , &c.; by passing moist SO_2 and air over hot Pt black (Phillips, *A.* 4, 171), through a red-hot tube containing pieces of glass (Magnus, *P.* 24, 610), or over red-hot sand (Blondeau, *C. R.* 29, 405).—5. By the oxidation of H_2S and polythionic acids (v. Cloëz a. Guignet, *C. R.* 46, 1110).—6. By the interaction of water and SO_2 , SO_2Cl_2 , $\text{SO}_2\text{Cl}_2\text{OH}$, &c.

Preparation.—Commercial oil of vitriol is diluted until the S.G. is 1.53 ($=50^\circ$ Beaumé, or 106° Twaddell, $=62.5$ p.c. H_2SO_4 by weight); the acid is heated to 70° – 80° , and $\text{Na}_2\text{S}_2\text{O}_3$ is added in quantity sufficient to decompose the As_2O_3 present (which should be estimated beforehand), according to the equation $3\text{Na}_2\text{S}_2\text{O}_3 + \text{As}_2\text{O}_3 = 3\text{Na}_2\text{SO}_4 + \text{As}_2\text{S}_3$; the acid is stirred until the As_2S_3 separates in flocks (Thorn, *D. P. J.* 217, 495); the acid is filtered from As_2S_3 through asbestos or glass-wool, and is then concentrated by evaporation in a Pt dish till it begins to fume, and then in a retort of Pt or hard glass. The conc. acid is now heated with a little pure $(\text{NH}_4)_2\text{SO}_4$, whereby HNO_3 and HNO_2 are decomposed (NH_4NO_2 and NH_4NO_3 are formed, and then decomposed to N and H_2O , and N_2O and H_2O). The acid is then distilled from a glass retort, heated by a ring-burner placed around the retort at about two-thirds of the distance from the level of the acid to the bottom of the retort. The distillate is re-distilled in small quantities from a Pt retort into a Pt receiver; the condenser being formed of Pt tubes, soldered with gold and fitting closely one into the other, and the temperature being such that the acid does not boil during the distillation (cf. Stas, *Chem. Proport.* 112). Various other methods for removing As have been proposed; for the preparation of H_2SO_4 free from As for chemico-medical use v. Bloxam (*C. J.* 15, 52), also Buignet a. Bussy (*J. Ph.* [3] 44, 177; 46, 252).

Commercial oil of vitriol is prepared by passing SO_2 , mixed with a little HNO_3 , into large leaden chambers into which jets of steam are also sent. The SO_2 is prepared by burning S or pyrites in a stream of air; the hot gas is passed over HNO_3 , or over pots containing KNO_3 and H_2SO_4 , so that it sweeps into the leaden chambers a certain quantity of HNO_3 . The interactions between the hot SO_2 and HNO_3 probably produce NO and N_2O , $3\text{SO}_2 + 2\text{HNO}_3 + 2\text{H}_2\text{O} = 3\text{H}_2\text{SO}_4 + 2\text{NO}$; and also $2\text{SO}_2 + 2\text{HNO}_3 + \text{H}_2\text{O} = 2\text{H}_2\text{SO}_4 + \text{N}_2\text{O}$; the NO then combines with O in the air of the chambers to form N_2O_4 ($4\text{NO} + \text{O}_2 = 2\text{N}_2\text{O}_4$), which interacts with SO_2 and H_2O to produce H_2SO_4 and $\text{NO}(\text{N}_2\text{O}_4 + \text{SO}_2 + \text{H}_2\text{O} = \text{H}_2\text{SO}_4 + 2\text{NO})$:—if N_2O_4 is produced in the primary reaction of SO_2 with HNO_3 , this N_2O_4 may take up O to form N_2O_5 , which in turn may react with SO_2 and H_2O to produce H_2SO_4 and $\text{NO}(\text{N}_2\text{O}_5 + 2\text{SO}_2 + 2\text{H}_2\text{O} = 2\text{H}_2\text{SO}_4 + 2\text{NO})$. These cycles of changes proceed as long as SO_2 is sent into the chambers, and there is present a sufficiency of O, H_2O , and oxides of N. If there is not sufficient H_2O present to complete the decomposition of N_2O_4 and SO_2 (or N_2O_5 and SO_2) to H_2SO_4 and NO , nitrosulphonic acid— $\text{NO}_2(\text{SO}_2\text{OH})$ —is formed as a solid on the sides of the chamber ($3\text{N}_2\text{O}_4 + 2\text{SO}_2 + \text{H}_2\text{O} = 2\text{NO}_2(\text{SO}_2\text{OH}) + 4\text{NO}$; or $3\text{N}_2\text{O}_5 + 4\text{SO}_2 + 2\text{H}_2\text{O} = 4\text{NO}_2(\text{SO}_2\text{OH}) + 2\text{NO}$);

when steam is now sent into the chamber the nitrosulphonic acid is decomposed to H_2SO_4 and N_2O ($2\text{NO}_2(\text{SO}_3\cdot\text{OH}) + \text{H}_2\text{O} = 2\text{H}_2\text{SO}_4 + \text{N}_2\text{O}$). It is possible that the formation of $\text{NO}_2(\text{SO}_3\cdot\text{OH})$ and the interaction of this with water may form normal stages in the series of reactions that occur in the chambers. Lunge (*C. J.* 47, 465) regards N_2O as the chief carrier of O from the air to the SO_2 ; he formulates the two main interactions as

moreover, he insists that the interactions take place for the most part between gases in contact with the surface of the vesicles of liquid water formed by the condensation of the steam sent into the chamber. (A fuller discussion of the reactions that occur in the leaden chambers will be found in the *DICTIONARY OF APPLIED CHEMISTRY*, vol. iii. p. 726.)

Some portion of the oxides of N is swept through the chambers and so lost (part of this is recovered in the Gay-Lussac towers); some is lost by leakage, solution in the acid formed in the chambers, and in other mechanical ways; but some portion of the available oxides of N is also destroyed by secondary reactions that occur in the chambers, and result in the formation of N_2O and sometimes of N or NH_3 (v. Weber, *P.* 180, 329; Pelouze, *A. Ch.* [2] 60, 162; Lunge, *B.* 14, 2196; cf. *DICTIONARY OF APPLIED CHEMISTRY*, vol. iii. p. 729).

Properties.—A clear, colourless, oily, hygroscopic liquid; solidifying at c. $10\cdot5^\circ$. The liquid may be cooled much below its freezing-point without solidifying, but addition of a crystal of H_2SO_4 or a small quantity of SO_2 causes crystallisation; the presence of a trace of water lowers the freezing-point to c. 0° . H_2SO_4 is exceedingly acid and burning, and is a violent poison. H_2SO_4 fumes very slightly in air at the ordinary temperature; at 30° – 40° it fumes much, giving off SO_3 ; according to Colefax (*C. N.* 63, 179), H_2SO_4 is probably slightly volatilised at ordinary temperatures. The mol. w. of H_2SO_4 has not been determined directly, but from the mol. weights of such derivatives as SO_2Cl_2 , $\text{SO}_2(\text{OMe})_2$, &c., the formula H_2SO_4 is most probably molecular. H_2SO_4 is decomposed when heated, and does not show a definite b.p.; boiling begins at c. 290° , and the temperature gradually rises to 338° , at which temperature dissociation to H_2O and SO_3 is complete. The residue has the composition $\text{H}_2\text{SO}_4\cdot\frac{1}{2}\text{H}_2\text{O}$; acid with this composition is obtained by boiling down either $\text{H}_2\text{SO}_4\cdot x\text{H}_2\text{O}$ or $\text{H}_2\text{SO}_4\cdot x\text{SO}_2$ (Marignac, *A. Ch.* [3] 39, 184; Dittmar, *C. J.* [2] 7, 446). The sp.gr. of the vapour given off at c. 440° corresponds with that calculated for the dissociation of H_2SO_4 into $\text{SO}_3 + \text{H}_2\text{O}$ (Deville & Troost, *C. R.* 56, 891; Wanklyn & Robinson, *Fr.* 12, 507). The b.p. of H_2SO_4 containing from 95 p.c. H_2SO_4 (b.p. = 295°), to 5 p.c. H_2SO_4 (b.p. 101°) is given by Lunge (*B.* 11, 370). H_2SO_4 freezes at $10\cdot352^\circ$ (v. Pickering, *C. J.* 57, 331; where a long series of determinations is given of f.p. of H_2SO_4 containing from .005 to 100 p.c. H_2SO_4). The S.H. and mol. heat (= S.H. \times 98) are given by Pfundler (*B.* 3, 798) as follows:

Temp. interval from 25°	S.H.	Mol. heat.
80°	·855	84·790
90	·856	84·888
100	·858	85·084
110	·859	85·182
120	·860	85·280
130	·862	85·476
140	·864	85·672
150	·865	85·770
160	·867	85·966
170	·870	86·260

For S.H. of $\text{H}_2\text{SO}_4\cdot x\text{H}_2\text{O}$ from 16° to 20° , x varying from 0 to 400, v. Marignac (*Ar. Sc.* 39, 217, 273); Bode (*Zeit. für anorg. Chemie*, 1889, 244) gives S.H. of H_2SO_4 from S.G. $1\cdot842$ to $1\cdot037$; Pickering (*C. J.* 57, 160) gives S.H. of H_2SO_4 from c. .2 to c. 12 p.c. H_2SO_4 dissolves in water in all proportions; much heat is produced, and contraction occurs; for thermal measurements v. Thomsen (*Th.* 3, 44), Favre & Silbermann (*C. R.* 24, 1081), F. a. Quillard (*C. R.* 50, 1150), Pfundler (*J.* 1869, 122), and, especially, Pickering (*C. J.* 57, 164). According to Pickering (*C. N.* 64, 14), the maximum contraction, calculated for unit weight of solution, changes from 67 p.c. at 8° , to $70\cdot1$ p.c. at 38° ; but the maximum is constant at 76 p.c., from 8° to 38° , if calculated for unit volume; for fuller data v. P. (*C. J.* 57, 148). The expansion of $\text{H}_2\text{SO}_4\cdot x\text{H}_2\text{O}$, at 20° , when x varies from 0 to 400, is given by Marignac (*Ar. Sc.* 39, 217, 273). The refractive indices and dispersion of H_2SO_4 containing from 93·87 to .088 p.c. H_2SO_4 are given by Pickering (*C. J.* 63, 99; cf. van der Willigen, *Ar. N.* 3, 122). Perkin (*C. J.* 63, 57) gives Mol. R. for H_2SO_4 from 99·92 to 9·18 p.c. H_2SO_4 (= from $\text{H}_2\text{SO}_4 + 53\cdot87 \text{H}_2\text{O}$ to $\text{H}_2\text{SO}_4 + \cdot004 \text{H}_2\text{O}$).

The electrical conductivities of H_2SO_4 of different concentrations have been measured by Kohlrausch (*P.* 154, 215; 159; 233; *W.* 6, 1; 17, 69), also by Pickering (*C. J.* 57, 158), who gives determinations for H_2SO_4 containing from 1 to 100 p.c. H_2SO_4 (v. also Bouty, *C. R.* 108, 393; also Grotrian, *P.* 151, 378).

The S.G. and composition of H_2SO_4 of varying concentrations have been determined by many observers. Pickering (*C. J.* 57, 152) gives S.G. and composition of H_2SO_4 containing from .5 to 100 p.c. H_2SO_4 at 0° , 2° , 4° , and each 2° up to 40° . Lunge & Isler (*Zeit. für anorg. Chemie*, 1890, 129) give the following tables (cf. Mendeleëff, *Z. P. C.* 1887, 273; Pickering, *C. N.* 64, 311; Lunge, *C. N.* 65, 13):—

For the properties of fuming H₂SO₄, v. PYRO-SULPHURIC ACID, p. 625.

For a test for small quantities of free H₂SO₄, v. Carey Lea (*Am. S.* [3] 45, 478; abstract in *C. J.* 64 (ii), 566).

Reactions.—1. Conc. H₂SO₄ is decomposed

by heat; at c. 440° the products are SO₃ and H₂O, and by passing through a red-hot tube SO₃, O, and H₂O are formed (Deville a. Troost, *C. R.* 56, 891; Wanklyn a. Robinson, *Pr.* 12, 507; Redwood, *Ph.* [2] 5, 601; Deville a. Debray, *A. Ch.* [3] 61, 125).—2. Decomposed by the electric current; with conc. H₂SO₄ and a raised temperature O separates at the positive pole, and H and S at the negative; at 0° only H and O are given off (Faraday, *T.* 1834; Warburg, *P.* 135, 114; Luckow, *Fr.* 1880. 1; Berthelot, *C. R.* 86, 71; 90, 269). Gladstone a. Tribe (*C. J.* 85, 176; 43, 345) found that a little SO₃ was formed when the electrolysis of 98.2 p.c. H₂SO₄ was very slow. According to the concentration of the H₂SO₄ electrolysed, the strength of the current, and the current density, ozone, H₂O₂, and S₂O₂ are formed, besides H and O. For an examination of the conditions favourable to the production of ozone v. McLeod (*C. J.* 49, 591, where references are given to earlier memoirs). According to Bouty (*C. R.* 108, 393), acid of the concentration H₂SO₄ + H₂O always gives H₂O₂ on electrolysis; Richarz (*A. Ch.* [2] 24, 183) says that the maximum production of H₂O₂ is obtained with acid of the concentration H₂SO₄ + 1.347H₂O; with acid more dilute than 60 p.c. H₂SO₄ very little H₂O₂ is obtained, but considerable quantities of S₂O₂ and ozone (Bouty, *l.c.*; cf. Kuriloff, *J. R.* 23, 285). In connection with the electrolysis of H₂SO₄ and the conditions of production of H and O only, or of H₂O₂, ozone, and S₂O₂, also, v. Armstrong (*C. J. Proc.* 1893-4. 188 [No. 127]).—3. By passing a mixture of the vapour of H₂SO₄ mixed with hydrogen through a red-hot tube, H₂O is obtained along with SO₂, S, or H₂S, according to the quantity of H (v. Warner, *C. N.* 28, 13). Hydrogen occluded by palladium or platinum partially reduces 98.2 p.c. H₂SO₄, giving SO₂ (G. a. T., *l.c.* p. 177).—4. SO₃, CO₂, and H₂O are formed by heating conc. H₂SO₄ with carbon; and SO₂ and H₂O by heating with sulphur.—5. Phosphorus takes fire in boiling H₂SO₄ with separation of S; red phosphorus reacts with the conc. acid when hot, forming SO₂ and H₂PO₃.—6. Chlorine reacts with conc. H₂SO₄ to form Cl(SO₂.OH) (v. CHLOROSULPHURIC ACID, p. 509).—7. Most metals interact; K and Na give off H, Zn and Fe and several other metals also give off H with more or less dilute H₂SO₄ at ordinary temperatures; on raising the temperature SO₂ and H₂S are generally evolved and S is often separated. Some metals, such as Sb, Bi, Cu, Hg, react only with warm fairly conc. H₂SO₄, giving off SO₂, and often also H₂S. Au, Ir, Pt, Rh, and W do not interact with H₂SO₄. Regarding the conditions of the interaction of H₂SO₄ with metals—concentration, temperature, and products—v. Ditte (*A. Ch.* [6] 19, 68). Pattison Muir a. Adie (*C. J.* 58, 47) found that the only products of the interaction of approximately pure zinc and dilute H₂SO₄ (c. H₂SO₄.12H₂O to c. H₂SO₄.15H₂O) were ZnSO₄ and H; that with conc. acid (c. H₂SO₄.H₂O to c. H₂SO₄.SO₃) was the chief gaseous product, and that H₂S was also produced at higher temperatures; and that with acid of intermediate concentration (c. H₂SO₄.2H₂O) both SO₂ and H₂S were formed in considerable quantities at c. 160°. For experiments on the rate of action of H₂SO₄ on

different specimens of zinc v. Divers a. Shimidzu (*C. J.* 47, 598), who have also examined the production of NH_4OH by the interaction of zinc with $\text{H}_2\text{SO}_4\text{Aq}$ and HNO_3Aq together (*cf.* *HYDROXYLAMINE*, vol. ii. p. 784). For qualitative experiments on the interaction of H_2SO_4 and *tin*, v. Pattison Muir a. Robbs (*C. N.* 45, 69, where references to other memoirs are given). Pullinger (*C. J.* 59, 815) found that *pure zinc* was not acted on by $\text{H}_2\text{SO}_4\text{Aq}$ (1 part conc. acid + 8 parts water by weight) provided the acid had been boiled for a long time before use and the surface of the zinc was quite smooth; if the surface was rough some of the zinc was dissolved. P. also found that oxidisers increased the rate of solution of zinc, and reducers, if not containing S, almost stopped the solution. P. concluded that when the surface of the zinc was rough S_2O_3 was probably formed, and then the action proceeded. Weeren (*B.* 24, 1785) noticed that there was scarcely any reaction between pure zinc and $\text{H}_2\text{SO}_4\text{Aq}$ (c. 20 parts water); he supposed that a layer of H was condensed on the surface of the metal. W. thought that with impure zinc the H is given off from the surface of the more negative metal present, and so the surface of the zinc is left exposed to the action of the acid. W. found that the evolution of H proceeded more rapidly *in vacuo*, and that it was hastened by brushing the surface of the metal. The weight of pure zinc dissolved in 80 mins. was 2.1 mgm. at 0° , 9.3 mgm. at 98° , and 122.1 mgm. at the b.p. of the acid used. W. obtained similar results with Al, Cd, Co, and Fe. *Sodium amalgam or zinc amalgam*, with conc. H_2SO_4 , gives off H, then quantities of H_2S , then SO_2 and S, and finally only SO_2 (Walz, *C. N.* 23, 245). The interaction of H_2SO_4 and *copper* has been fully examined by Pickering (*C. J.* [2] 18, 112; *cf.* *COPPER*, vol. ii. p. 253).—8. H_2SO_4 reacts with the *oxides of nitrogen* (not with N_2O) to form $\text{NO}_2(\text{SO}_2\text{OH})$ (*v.* *NITROSULPHURIC ACID*, p. 601).—9. *Phosphoretted hydrogen* reacts slowly with H_2SO_4 at the ordinary temperature, giving SO_2 , S, and H_3PO_4 (Rose, *P.* 24, 189).—10. With *sulphuretted hydrogen*, H_2O , S, and SO_2 are formed.—11. *Phosphorus pentoxide* withdraws H_2O from hot conc. H_2SO_4 , producing $\text{P}_2\text{O}_5\cdot\text{H}_2\text{O}$ and SO_3 (Barreswil, *C. R.* 25, 80; Evans, *Ph.* 8, 127); *phosphorus pentachloride* or *trichloride* forms SO_2 and POCl_3 , also SO_2Cl_2 when PCl_5 is used (Williamson, *P. M.* [4] 7, 865; Schiff, *A.* 202, 111; *cf.* Michaelis, *J. Z.* 6, 233, 292), and also $\text{Cl}(\text{SO}_2\text{OH})$ (Müller, *B.* 6, 277; Geuther, *B.* 5, 925; Thorpe, *C. J.* 37, 358).—12. H_2SO_4 reacts with most *salts* to form sulphates, and set free the acid of the salt if that acid is more volatile than H_2SO_4 . In several cases secondary reactions occur between the acid set free and the H_2SO_4 ; thus, with bromides and iodides, Br and I, and SO_2 or H_2S , are produced. The interaction of $\text{H}_2\text{SO}_4\text{Aq}$ and KBr has been examined by Addyman (*C. J.* 61, 94), who found that the percentage of HBr decomposed varied almost directly with the quantity of H_2SO_4 used, and that when so much H_2SO_4 was present that the water produced in the reaction $2\text{HBr} + \text{H}_2\text{SO}_4 = 2\text{H}_2\text{O} + \text{SO}_2 + \text{Br}_2$ caused no sensible dilution of the H_2SO_4 , all the HBr was decomposed; with dilute acid, c. 80 p.p. H_2SO_4 , using excess of acid, scarcely a trace of HBr was decomposed (*cf.* Feit a. Kubierschki,

J. Ph. [5] 24, 159). Jackson (*O. J.* 43, 339) finds that the interaction of conc. H_2SO_4 and KI varies according as the acid is present in large excess, or in quantity just sufficient for the KI used. In the first case all the I of the KI is set free along with an equivalent quantity of SO_2 ; in the second case all the I is liberated with the equivalent quantity of H_2S . Many *salts of acids containing much oxygen*, e.g. dichromates and permanganates, are decomposed by hot conc. H_2SO_4 with evolution of O. The reaction of $\text{H}_2\text{SO}_4\text{Aq}$ with KMnO_4Aq has been examined by Gooch a. Danner (*Am. S.* [3] 44, 801), who found that the quantity of O given off increased with (1) concentration of $\text{H}_2\text{SO}_4\text{Aq}$, (2) time, (3) temperature; no O was given off after a few hours with 20 p.p. acid at the ordinary temperature, but a considerable quantity of O was produced after five days' action, and c. the same result was obtained by heating to 80° for one and a half hours (*cf.* Jones, *C. J.* 33, 95).—13. Conc. H_2SO_4 reacts with many oxygenated *organic compounds*, withdrawing H_2O ; with benzenoid hydrocarbons it forms sulpho-acids; many organic compounds, such as sugar, starch, &c., are charred by warm H_2SO_4 .—14. Pictet (*C. R.* 115, 708, 814) has examined the *reactions of sulphuric acid at low temperatures*, using acid of 89 p.p. H_2SO_4 ; no action occurred below -125° with such bodies as NaOH , NaCl , NH_3 , Na_2CO_3 , Na, K; in most cases action began suddenly at temperatures varying from -120° to -60° .—15. H_2SO_4 combines with *water*; the hydrates $\text{H}_2\text{SO}_4\cdot\text{H}_2\text{O}$, $\text{H}_2\text{SO}_4\cdot 2\text{H}_2\text{O}$, and $\text{H}_2\text{SO}_4\cdot 3\text{H}_2\text{O}$ have been isolated as solids (*v. infra*).—16. Conc. H_2SO_4 combines with *sulphur trioxide* to form $\text{H}_2\text{SO}_4\cdot\text{SO}_3$ and other compounds (*v.* *PYROSULPHURIC ACID*).

For the reactions of fuming H_2SO_4 , v. *PYROSULPHURIC ACID* (p. 625). The salts of H_2SO_4 are described under *SULPHATES* (p. 567). Both amides of H_2SO_4 , viz. $\text{SO}_2\cdot\text{OH}\cdot\text{NH}_2$ and $\text{SO}_2(\text{NH}_2)_2$, have been isolated (*v.* *SULPHAMIC ACID*, p. 567, and *SULPHAMIDE*, p. 567); the imide $\text{SO}_2\cdot\text{NH}$ is also known, *v.* *SULPHIMIDE*, p. 587; *cf.* also *SULPHIMIDO-AMIDE* $\text{NH}(\text{SO}_2\cdot\text{NH}_2)$, p. 587, and *IMIDO-SULPHURIC ACID* $\text{NH}(\text{SO}_2\cdot\text{OH})$, p. 600.

Constitution of sulphuric acid.—The reactions of H_2SO_4 with Cl and with PCl_5 , and the reactions of the products with water, also the formation of $\text{SO}_2\cdot\text{OH}\cdot\text{NH}_2$, $\text{SO}_2(\text{NH}_2)_2$, and $\text{SO}_2\cdot\text{NH}$, show that H_2SO_4 contains two OH groups. The fact that only one compound, $\text{SO}_2\cdot\text{OEt}\cdot\text{OMe}$, can be formed from H_2SO_4 , shows that the two OH groups in $\text{SO}_2(\text{OH})_2$ are related to the rest of the molecule in the same way; hence the formula for the acid is to be written

is formed from $\text{SO}_2(\text{OH})_2$, by the reaction of PCl_5 , as certain hydrocarbons interact with SO_2Cl_2 to form SO_2R_2 (where $\text{R} = \text{Me}$, Ph , &c.), and as these compounds SO_2R_2 are reduced to SR_2 , where the radicles R are certainly in direct union with S, it is extremely probable that the OH groups in $\text{SO}_2(\text{OH})_2$ are in direct union with

S, and hence the formula $\text{O}_3\text{S} \begin{smallmatrix} \text{OH} \\ \text{OH} \end{smallmatrix}$ is to be preferred to $\text{S} \begin{smallmatrix} \text{O} \cdot \text{OH} \\ \text{O} \cdot \text{OH} \end{smallmatrix}$ for sulphuric acid. It is

undecided whether the group SO_2 in $\text{O}_2\text{S.OH.OH}$ has the constitution O.S.O or $\text{S} \begin{smallmatrix} \diagup \text{O} \\ \diagdown \text{O} \end{smallmatrix}$.

HYDRATES OF SULPHURIC ACID. Two solid hydrates have been isolated; a liquid hydrate has probably also been isolated.

Monohydrate $\text{H}_2\text{SO}_4 \cdot \text{H}_2\text{O}$ (*Tetrahydroxy-sulphuric acid* $\text{SO}(\text{OH})_4$). Large, colourless, six-sided tablets; formed by mixing 1 part conc. H_2SO_4 with rather less than one-fifth part water (by weight), and surrounding with a freezing mixture. The crystals melt at 7.5° (Pierre a. Puchot, *A. Ch.* [5] 2, 164). The hydrate readily remains liquid considerably below its m.p. S.G. $_{20}^\circ = 1.7943$ (for the liquid) (Mendeléeff, *B.* 19, 380); 1.77806 at 15° , 1.77423 at 20° , 1.77071 at 25° (Perkin, *C. J.* 49, 777; determinations made with liquid, and referred to water at same temperatures). Thomsen gives H.F. from liquid H_2SO_4 and H_2O $[\text{H}^+\text{SO}_4, \text{H}^+\text{O}] = 6.379$ (*Th.* 3, 54); Berthelot gives 6,120 (*C. R.* 78, 716). Heat of fusion = 3680 g. units (for 116 g.) $\text{H}_2\text{SO}_4 \cdot \text{H}_2\text{O}$ (Berthelot, *C. R.* 78, 716). For vapour pressures from 143° to 204° v. Tate (*P. M.* [4] 26, 502).

Dihydrate $\text{H}_2\text{SO}_4 \cdot 2\text{H}_2\text{O}$ (*Perkydroxysulphuric acid* $\text{S}(\text{OH})_6$). Formed by adding 368 parts H_2O to 1 part pure H_2SO_4 , by weight. This hydrate has not been obtained as a solid; the S.G. of the liquid at 20° is given by Mendeléeff (*B.* 19, 380) as 1.6655 (*cf.* Perkin, *C. J.* 49, 777).

It is stated (v. Mendeléeff, *B.* 19, 388) that the maximum contraction when H_2SO_4 and H_2O are mixed occurs when the compounds are present in the ratio $\text{H}_2\text{SO}_4 : 2\text{H}_2\text{O}$, but Pickering (*C. J.* 57, 84) says that the maximum does not correspond with the composition of any hydrate the existence of which is indicated in other ways.

Tetrahydrate $\text{H}_2\text{SO}_4 \cdot 4\text{H}_2\text{O}$. Obtained by Pickering (*C. J.* 57, 339) as a crystalline solid, melting at -25° , by cooling H_2SO_4 aq containing 57.6 p.c. H_2SO_4 ($\text{H}_2\text{SO}_4 \cdot 2\text{H}_2\text{O}$ corresponds with 57.66 p.c. H_2SO_4). The crystals are large and well defined, and resemble $\text{H}_2\text{SO}_4 \cdot \text{H}_2\text{O}$; the compound may be kept liquid at 20° to 25° below its freezing point.

Hydrates of sulphuric acid in aqueous solution.—According to Mendeléeff (*B.* 19, 380; *cf.* his *Principles of Chemistry*, vol. ii. p. 234), an examination of the connections between the concentration of H_2SO_4 aq and the S.G. indicates the existence of hydrates that have not yet been isolated. Pickering (*C. J.* 57, 64) comes to the same general conclusion from an extended examination of the connections between the changes of composition of H_2SO_4 aq and the changes of S.G., heat capacity, electrical conductivity, heat of solution, and expansion by heat of the solution. Pickering's reasoning is a special case of that explained in the article SOLUTIONS (part ii. p. 492); for the detailed argument, and criticisms of it, v. Pickering, *C. J.* 57, 64; Rücker, *P. M.* [5] 82, 304; 33, 204; P., *P. M.* [5] 83, 182, 463; *cf.* Mendeléeff, *Z. P. C.* 1, 275; and Crompton, *C. J.* 53, 116.

PERSULPHURIC ACID $\text{H}_2\text{S}_2\text{O}_8$ aq. This acid is present in the solution obtained by elec-

trolysing H_2SO_4 aq of certain concentrations; Berthelot (*C. R.* 90, 269; 112, 1481) obtained a quantity of the acid equal to from 88 to 123 g. S_2O_8 , per litre by electrolysing H_2SO_4 aq containing water and acid in the ratio $10\text{H}_2\text{O}:\text{H}_2\text{SO}_4$, (*cf.* SULPHURIC PEROXIDE, p. 616; and SULPHURIC ACID, *Reactions*, No. 2, p. 623). According to Traube (*B.* 22, 1518, 1528) a solution of $\text{H}_2\text{S}_2\text{O}_8$ in H_2SO_4 does not oxidise $\text{H}_2\text{C}_2\text{O}_4$, HNO_3 , CO , or $\text{Cr}_2(\text{SO}_4)_3$; Richarz, however (*B.* 21, 1670), says that oxalic and nitrous acids are oxidised. The acid has not been isolated; by electrolysing at temperatures below 0° , and then adding BaO aq or KOH aq, the Ba or K salt is obtained. The formula $\text{H}_2\text{S}_2\text{O}_8$ is given rather than HSO_5 , because of the results of Bredig's measurements of the conductivities of solutions of the K salt. For salts of this acid v. PERSULPHATES, p. 582.

PYROSULPHURIC ACID $\text{H}_2\text{S}_2\text{O}_7$ (*Disulphuric acid*). A solution of this acid in H_2SO_4 is known as *fuming sulphuric acid*, or *Nordhausen acid*. This acid is obtained by adding rather more SO_3 to H_2SO_4 than the proportion $\text{SO}_3:\text{H}_2\text{SO}_4$, cooling, and spreading out the crystals that form over nearly conc. H_2SO_4 under a bell-jar till the excess of SO_3 is removed (Schultz-Sellack, *B.* 4, 109). Forms large crystals, melting at 35° . Easily decomposed by heat to H_2SO_4 and SO_3 . $\text{H}_2\text{S}_2\text{O}_7$ is dibasic, forming salts MHSO_5 and $\text{M}_2\text{S}_2\text{O}_7$ (v. PERSULPHATES, p. 583). *Fuming sulphuric acid* is a solution of $\text{H}_2\text{S}_2\text{O}_7$ in H_2SO_4 ; it is prepared by heating dry FeSO_4 in fireclay vessels and collecting the oily, fuming liquid that distils over. The acid fumes strongly in the air, and gives off SO_3 when warmed. But few of the reactions described for *pyrosulphuric acid*, or for *fuming sulphuric acid*, can be set down as belonging to a definite compound, but rather to solutions of $\text{H}_2\text{S}_2\text{O}_7$ (and perhaps other compounds of H_2SO_4 and SO_3) in H_2SO_4 . Finely-divided silver dissolves easily; the solution poured into water gives Ag_2SO_4 and SO_2 ; mercury reacts similarly; spongy copper has a slight reaction, giving Cu_2S and CuSO_4 (Divers a. Shimidzu, *C. J.* 47, 636). Distilled with phosphorus pentoxide in a stream of hydrogen chloride, $\text{Cl}(\text{SO}_3\text{OH})$ is formed; the same acid is formed by heating with PCl_5 , and also by heating 'crystallised fuming sulphuric acid' with HCl (v. CHLOROSULPHONIC ACID, p. 509). Nitrogen dioxide passed into well-cooled pyrosulphuric acid gives $\text{NO}_2(\text{SO}_3\text{OH})$ (v. NITROSULPHONIC ACID, p. 601). By saturating ordinary conc. H_2SO_4 with SO_3 (Jacquelin, *A. Ch.* [3] 80, 848), or by cooling fuming H_2SO_4 to -10° (Waackener, *Ar. Ph.* [2] 87, 267), the compound $\text{H}_2\text{S}_2\text{O}_7 \cdot 2\text{H}_2\text{SO}_4$ ($= 3\text{H}_2\text{SO}_4 \cdot \text{SO}_3$) is said to be obtained in transparent crystals. Schultz-Sellack (*B.* 4, 109) failed to obtain any compound of H_2SO_4 and SO_3 , except $\text{H}_2\text{S}_2\text{O}_7$. Crystals of the composition $\text{H}_2\text{SO}_4 \cdot 3\text{SO}_3$ ($= \text{H}_2\text{S}_3\text{O}_{10}$) melting at 8° – 10° are said by Weber (*P.* 159, 313) to be formed by adding cooled conc. H_2SO_4 , little by little, to SO_3 . M. M. P. M.

SULPHUROSAMIC ACID SO.OH.NH_2 v.

THIONAMIC ACID, p. 695.

SULPHUROUS ACID and HYPOSULPHUROUS ACID.

SULPHUROUS ACID $\text{H}_2\text{SO}_3\text{Aq}$. The acid has not been isolated; a solution of SO_2 in water reacts as a weak dibasic acid, forming salts of the types M^+HSO_3 , M^+SO_3 , and M^{++}SO_3 (v. SULPHITES, p. 587). H.F. $[\text{H}^+\text{S}_2\text{O}_3\text{Aq}] = 147,130$; $[\text{H}^+\text{O}_3\text{S}_2\text{O}_3\text{Aq}] = 78,780$ (from rhombic S; *Th.* 2, 251).

The methods of formation and preparation of $\text{H}_2\text{SO}_3\text{Aq}$ are sufficiently detailed under SULPHUR DIOXIDE (p. 613); it is only necessary to add water to the SO_2 obtained.

Properties.—An aqueous solution of H_2SO_3 readily decomposes, giving off SO_2 ; on standing for some time in the air, and more quickly by warming, $\text{H}_2\text{SO}_3\text{Aq}$ is formed with production of much heat; $[\text{H}^+\text{SO}_3\text{Aq.O}] = 63,634$ (*Th.* 2, 253). $\text{H}_2\text{SO}_3\text{Aq}$ is altered by the action of light, so that after exposure to light for some time the solution ppts. Ag_2S from AgNO_3Aq , and reduces silver haloid compounds, forming some Ag_2S ; the solution after exposure to light behaves like a dilute solution of a polythionic acid (*Stas, Chem. Proport.* 64). Löw (*L'Institut*, 1873. 67) says that dilute $\text{H}_2\text{SO}_3\text{Aq}$ is changed to $\text{H}_2\text{SO}_4\text{Aq}$ and S by long exposure to light.

Reactions.—1. Heated in a closed tube to 170° – 180° , $\text{H}_2\text{SO}_3\text{Aq}$ and S are formed, and after a time also H_2S (Geitner, *A.* 129, 350).—2. Decomposed by an electric current, giving $\text{H}_2\text{SO}_3\text{Aq}$ at the positive pole and S at the negative; with a weak current $\text{H}_2\text{SO}_3\text{Aq}$ is probably formed at first at the negative pole (Gugérout, *C. R.* 85, 225).—3. Phosphorus pentachloride produces SOCl_2 and POCl_3 (Kremers, *A.* 70, 297; Schiff, *A.* 102, 111).—4. Sulphurous chloride with $\text{H}_2\text{SO}_3\text{Aq}$ produces polythionic acids (v. Debus, *C. J.* 53, 345).—5. Vapour obtained by heating $\text{H}_2\text{SO}_3\text{Aq}$ reacts with chlorine, when passed over red-hot Pt, to form $\text{Cl}(\text{SO}_2\text{OH})$ (v. CHLOROSULPHONIC ACID, p. 599).—6. $\text{NO}_2(\text{SO}_2\text{OH})$ (v. NITROSULPHONIC ACID, p. 601) is formed by the interaction of moist SO_2 , i.e. $\text{H}_2\text{SO}_3\text{Aq}$, with nitric oxide or nitrogen dioxide.—7. $\text{H}_2\text{SO}_3\text{Aq}$ is oxidised to $\text{H}_2\text{SO}_4\text{Aq}$ by oxygen, the halogens, and many other oxidisers.—8. Heated with phosphorus in a closed tube to 200° , H_2S is produced (Oppenheim, *Bl.* [2] 1, 163).—9. Reduced by zinc and dilute sulphuric acid to H_2S (v. Reinsch, *D. P. J.* 163, 286; 181, 832); with zinc alone, $\text{H}_2\text{SO}_3\text{Aq}$ is partly reduced, probably giving $\text{H}_2\text{S}_2\text{O}_3\text{Aq}$ (v. HYPOSULPHUROUS ACID, p. 627).—10. Many metals which evolve H from $\text{H}_2\text{SO}_4\text{Aq}$ or HClAq react with $\text{H}_2\text{SO}_3\text{Aq}$ to form sulphites and sulphides, with evolution of little or no H (v. Federoff, *Chem. Zeitung*, 5, 15). For a fairly full qualitative examination of the interaction of Al, Cd, Mg, Ni, and Zn with $\text{H}_2\text{SO}_3\text{Aq}$, v. Schweitzer (*C. N.* 23, 293).—11. Many of the oxyacids of the halogens are reduced to hydrazides by $\text{H}_2\text{SO}_3\text{Aq}$.—12. Phosphorous acid gives $\text{H}_3\text{PO}_3\text{Aq}$ and H_2S ; then S, and thionic acids (Wöhler, *A.* 89, 252; Maquenne, *Chem. Zeitung*.

1890 [1] 511).—13. Phosphoretted hydrogen produces $\text{H}_3\text{PO}_3\text{Aq}$, and S (Cavazzi, *G.* 16, 169).—14. Hydrogen sulphide passed into $\text{H}_2\text{SO}_3\text{Aq}$ forms a solution containing H_2SO_3 , $\text{H}_2\text{S}_2\text{O}_3$, $\text{H}_2\text{S}_3\text{O}_3$, probably $\text{H}_2\text{S}_4\text{O}_3$, S in suspension, and a colloidal form of S in solution; if the passage of H_2S is continued until reaction ceases the final products are S and H_2O (Debus, *C. J.* 53, 282; cf. THIONIC ACIDS, p. 698).—15. Many metallic salts are reduced, in aqueous solutions, by $\text{H}_2\text{SO}_3\text{Aq}$; salts of Ag and Hg to the metals, ferric to ferrous salts, &c. According to Divers a. Shimidzu (*C. J.* 49, 575), the reduction does not consist in the withdrawal of O by $\text{H}_2\text{SO}_3\text{Aq}$ and the oxidation of that acid thereby to $\text{H}_2\text{SO}_4\text{Aq}$. The first step is looked on by D. a. S. as probably the formation of a sulphite of the metal of the salt, and this is followed by either the decomposition of this sulphite by water to metal and $\text{H}_2\text{SO}_4\text{Aq}$, or the reaction of the sulphite with some of the original, unchanged, salt to form metal and a persulphite (or -io sulphite) of the metal.—16. With potassium thiosulphate $\text{H}_2\text{SO}_3\text{Aq}$ forms K tri- tetra- and penta-thionates, and S (Debus, *C. J.* 53, 343).—17. $\text{H}_2\text{SO}_3\text{Aq}$ dissolves many freshly ppd. metallic sulphides, e.g. MnS , FeS , ZnS , forming thiosulphates (Schönbein, *P.* 104, 300; Heldt, *J. pr.* 83, 20).—18. Alkali nitrites give salts of nitrosulphonic acid $\text{N}(\text{SO}_2\text{OH})$, (q. v., p. 601), and also salts of oxy-imidosulphonic acid $\text{N}(\text{OH})(\text{SO}_2\text{OH})_2$ (q. v., p. 602). Using a dilute, ice-cold solution of H_2SO_3 (= 5 p.c. SO_2), and adding 40 g. KNO_3 in 1,000 c.c. water to 3 litres of this $\text{H}_2\text{SO}_3\text{Aq}$, Raschig (*A.* 241, 234) obtained $\text{NH}_2(\text{SO}_2\text{OK})$ (cf. SULPHAMIC ACID, p. 567). Under certain conditions of concentration and temperature NO and N_2O , also NH_3 and sometimes NH_4OH , are produced. With nitrous acid the final products are NH_3 , NO, N_2O , and $\text{H}_2\text{SO}_4\text{Aq}$; according to Raschig (*l.c.*), $\text{NH}_2(\text{SO}_2\text{OH})$ is always formed, and the gaseous products are to be looked on as resulting from secondary reactions between nitrous acid and $\text{NH}_2(\text{SO}_2\text{OH})$ or other nitrogenised sulphonic acids formed in the primary reaction between the nitrous and sulphurous acids. With silver and mercurous nitrites Divers a. Haga (*C. J.* 51, 659) found that sulphites were produced, along with some NO and H_2SO_3 , and more or less NH_4OH .—19. For the reaction of $\text{H}_2\text{SO}_3\text{Aq}$ with potassium platinochloride v. PLATINO-SULPHONATES, this vol., p. 285.

Neither the amide $\text{SO}(\text{NH}_2)_2$ (v. the heading THIONAMIDE), nor the imide SO.NH , of H_2SO_3 has been isolated; and it is doubtful whether the acid SO.OH.NH_2 or $\text{SO}_2\text{NH}_2\text{H}$ is known v. THIONAMIC ACID.

Constitution of sulphurous acid. The fact that many haloid derivatives of hydrocarbons interact with NaHSO_3 to form sulphonic acids—e.g. $\text{EtI} + \text{NaHSO}_3 = \text{EtSO}_3\text{H} + \text{NaI}$ —makes it probable that the Na in NaHSO_3 is in direct union with the S, because the S in sulphonic acids is almost certainly in direct union with the hydrocarbon radicle; hence it is likely that one H atom in H_2SO_3 is directly combined with the S atom, and hence the formula for H_2SO_3 is probably $\text{H.SO}_2\text{OH}$. This view of the constitution of H_2SO_3 is insisted on, and illustrated, by Divers (*C. J.* 47, 205).

Hydrates of sulphurous acid. Colourless, ice-like crystals are obtained by passing SO_2 into water surrounded by ice, by cooling saturated SO_2Aq , or by passing moist SO_2 through a tube kept at a low temperature. After filtering quickly in a covered filter, and pressing between filter paper at 8° , the crystals have the composition $\text{H}_2\text{SO}_3 \cdot x\text{H}_2\text{O}$; Dopping (*Petersburg Acad. Bull.*, 7, 100) found $x=10$, Pierre (*A. Ch.* [3] 23, 416) found $x=8$, Schönfeld (*A.* 95, 22) found $x=14$, Roozeboom (*R. T. C.* 3, 29, 59, 75, 84; 4, 65) found $x=6$, and this was confirmed by Geuther (*A.* 224, 218). Roozeboom (*l.c.*) gives S.G. of the crystals as 1.21 (referred to water at 4°); Geuther (*l.c.*) gives 1.147 as the S.G. after melting at 14° , and 14° as the m.p. with separation of some liquid SO_2 under the layer of SO_2Aq . R. (*l.c.*) gives the following dissociation-pressures, which are independent of the quantity of the hydrate: 303 mm. at 0° , 754 mm. at 7.05° , 1177 mm. at 10° , 1773 mm. at 12.1° . According to R. the critical temperature of decomposition is 7.1° in an open vessel and 12.1° in a closed vessel.

HYPOSULPHUROUS ACID $\text{H}_2\text{S}_2\text{O}_4\text{Aq}$. This acid has not been isolated. An aqueous solution is probably formed by decomposing the Na salt by dilute $\text{H}_2\text{SO}_4\text{Aq}$ or $\text{H}_2\text{C}_2\text{O}_4\text{Aq}$, and also perhaps by digesting $\text{H}_2\text{SO}_4\text{Aq}$ with zinc clippings till the liquid is brownish red; but neither the aqueous solution of the acid, nor any of its salts, has been obtained free from impurities. For preparation of the sodium salt, and for references, v. **HYPOSULPHITES** (p. 592).

SULPHUVINURIC ACID $\text{C}_6\text{H}_4\text{N}_2\text{SO}_2$, i.e. $\text{S}-\text{C}(\text{NH}_2)_2 \gg \text{N}$ (Strände, *A.* 261, 26). Formed from di-bromo-pyruvic acid and a conc. solution of thio-urea (Nencki a. Sieber, *J. pr.* [2] 25, 74). Crystals (containing 2aq), sl. sol. cold water. Reduces Fehling's solution in the cold. FeCl_3 gives a deep violet colour.—Salts: MgA'_2 .—

ZnA'_2 : minute needles.— $\text{HA}'\text{HCl}$.— $\text{HA}'\text{HBr}$.— $\text{HA}'\text{HNO}_3$ aq: needles, sl. sol. water.

SULPHYDRO-ACETIC ACID v. **THIOGLYCOLLIC ACID**.

SULPHYDRO-ACETONE $\text{CH}_3\text{COCH}_2\text{SH}$.

Ethyl derivative $\text{EtS.CH}_2\text{Ac}$. [171°].

Formed from chloro-acetone and NaSEt (Autenrieth, *B.* 24, 165). Yields a phenyl hydrazide [57°].

Phenyl derivative $\text{PhS.CH}_2\text{Ac}$. [86°]. (266°). Formed from $\text{CH}_3\text{COCH}_2\text{Cl}$ and NaSPh in alcohol in the cold. Crystals. Yields a phenyl-hydrazide [87°] (A., cf. Delisle, *A.* 260, 250). Combines with KHSO_4 and NaHSO_4 .

SULPHYDRO-ACETOPHENONE. *Phenyl derivative* $\text{C}_6\text{H}_5\text{SO}_2\text{CH}_3$, i.e.

$\text{C}_6\text{H}_5\text{S.CH}_2\text{CO.C}_6\text{H}_5$. [53°]. Formed from ω -bromo-acetophenone and NaOPh (Delisle, *B.* 22, 309). Needles (from alcohol), v. sol. ether and acetone.

SULPHYDRO-ACETYL-PROPIONIC ETHER.

Phenyl derivative $\text{C}_6\text{H}_5\text{SO}_2\text{CH}_2\text{CH}_2\text{COEt}$, i.e.

$\text{C}_6\text{H}_5\text{S.CH}_2\text{CO.CH}_2\text{CH}_2\text{COEt}$. (197° at 15 mm.). Formed from bromo-acetyl-propionic ether and NaSPh (Delisle, *B.* 22, 309).

SULPHYDRO-ALLYL-QUINAZOLINE. *Dihydride* $\text{C}_6\text{H}_4\text{CH}_2\text{N.C}_6\text{H}_4$, [91°]. Formed from ω -oxy-tolyl-allyl-thio-urea and HClAq at 100° (Söderbaum a. Widman, *B.* 22, 1670). Needles, v. e. sol. alcohol and benzene.

Reference.—**OXY-SULPHYDRO-ALLYL-QUINAZOLINE**.

DISULPHYDRO-DI-ALLYL-TRIAZOLE

$\text{NH} \left\langle \begin{smallmatrix} \text{CS.N.C}_6\text{H}_5 \\ \text{CS.N.C}_6\text{H}_5 \end{smallmatrix} \right.$. Formed from allyl-thio-urea and HNO_2 (Hector, *J. pr.* [2] 44, 505). Oil.— $\text{B}'_2\text{H}_2\text{PtCl}_2$: crystalline pp.

***o*-SULPHYDRO-BENZOIC ACID**

$\text{C}_6\text{H}_4(\text{SH}).\text{CO}_2\text{H}$. *Thio-salicylic acid*. Formed by reducing ω -sulpho-benzoic chloride with zinc-dust and H_2SO_4 (Delisle, *B.* 22, 2206). Amorphous powder, sl. sol. hot water, v. sol. alcohol.

Not volatile with steam.— AgA' .

Thio-amide $\text{C}_6\text{H}_4(\text{SH}).\text{CS.NH}_2$. Formed by heating ω -oxy-benzamide with P_2S_5 (Spilker, *B.* 22, 2771). Minute dark-red crystals.

Phenyl derivative $\text{C}_6\text{H}_5\text{S.C}_6\text{H}_4\text{CO}_2\text{H}$. [166°]. Formed from α -diazobenzoic acid, phenyl mercaptan, and NaOHAq at 50° (Graebe a. Schultess, *A.* 263, 4). Plates (from alcohol) or needles (from HOAc); sl. sol. water.— $\text{NH}_4\text{A}'$.

— KA' : needles, v. sol. water.— EtA' . [151°].

m-Sulphydro-benzoic acid $\text{C}_6\text{H}_4(\text{SH}).\text{CO}_2\text{H}$. [147°]. Formed by the action of tin and HClAq on $\text{C}_6\text{H}_4(\text{SO}_2\text{Cl}).\text{COCl}$ (Fericichs, *B.* 7, 793). Colourless plates, m. sol. water.— BaA'_2 , 2½aq.— HgA'_2 .— $\text{PbC}_6\text{H}_4\text{SO}_2$ 3aq.— $\text{Cu}(\text{OH})\text{A}'$.— AgA' .

***α*-SULPHYDRO-BUTYRIC ACID**

$\text{OHEt}(\text{SH}).\text{CO}_2\text{H}$. Formed from α -bromo-butyric acid and alcoholic KSH (Duvillier, *Bl.* [2] 30, 507). Sol. water, alcohol, and ether.

Sulphydro-isobutyric acid $\text{HS.OMe}_2.\text{CO}_2\text{H}$. Formed from α -bromo-isobutyric ether by successive treatment with alcoholic K_2S and alcoholic KOH (Lovén, *J. pr.* [2] 33, 109). Oil.

***α*-SULPHYDRO-CINNAMIC ACID**

$\text{C}_6\text{H}_5\text{CH}:\text{C}(\text{SH}).\text{CO}_2\text{H}$. [119°]. Formed, together with sulphocyanic acid, by heating benzylidene-rhodanic acid $\text{C}_6\text{H}_5\text{CH}:\text{C}(\text{SH}).\text{CO}_2\text{S.ON}$ with baryta-water (Ginsburg a. Bondzynski, *B.* 19, 123; *M.* 8, 850). Yellowish crystals. V. sol.

alcohol, ether, benzene, and CS_2 , nearly insol. water. By treatment with iodine in alcoholic solution it is oxidised to di-sulphido-di-cinnamic acid $\text{S}_2(\text{C}_6\text{HPh.CO}_2\text{H})_2$.

Reference.—NITRO-SULPHYDRO-CINNAMIC ACID.

β -SULPHYDRO-CROTONIC ACID. *Ethyl derivative* $\text{CH}_3\text{C}(\text{SEt})\text{:CH.CO}_2\text{H}$. [113°]. Formed from β -chloro-crotonic acid [94.5°], mercaptan, and Na (Autenrieth, A. 254, 235; B. 20, 3189). Crystals, insol. water, v. sol. ether and alcohol. Gives a dark-green colour on warming with isatin and H_2SO_4 . Yields $\text{CH}_3\text{C}(\text{SEt})\text{:CH}_2$ (110°) on heating above its melting-point.— BaA'_2 , aq.— AgA' : silky needles, not decomposed by hot water. Ac_2O forms the compound $\text{CH}_3\text{C}(\text{SEt})\text{:CH.CO.OAc}$, a brownish oil.

Isomeric derivative of the ethyl derivative $\text{CH}_3\text{C}(\text{SEt})\text{:CH.CO}_2\text{H}$. [92°]. S. (alcohol) 20. Formed in like manner from the isomeric β -chloro-crotonic acid (A). Crystals, nearly insol. water. Forms a dark-green liquid on warming with isatin and H_2SO_4 . When heated alone it yields the same ethyl-sulphydro-propylene (110°) as its isomeric.— BaA'_2 , aq.: thin plates (from Aq).

Phenyl derivative v. PHENYL-SULPHYDRO-CROTONIC ACID.

SULPHYDRO-ETHYL ALCOHOL

$\text{HO.C}_2\text{H}_4\text{.SH}$. Formed from glycolic chlorhydrin and alcoholic KSH (Carius, A. 124, 258). Oil, v. e. sol. alcohol. Oxidised by HNO_3 to isethionic acid— $\text{Hg}(\text{C}_2\text{H}_4\text{OS})_2$. Needles (from warm alcohol).

SULPHYDRO - ETHYL - QUINAZOLINE.

Dihydrate $\text{C}_6\text{H}_4\text{.}\begin{smallmatrix} \text{CH}_2\text{.NEt} \\ \text{NH.CS} \end{smallmatrix}$. [103°]. Formed by warming ω -tolyl-ethyl-thio-urea with HCl (Söderbaum a. Widman, B. 22, 2936). Needles.— B'HauCl_4 . [118°].— $\text{B'H}_2\text{PtCl}_6$. [208°].

SULPHYDRO - METHANE DISULPHONIC ACID $\text{HS.CH}(\text{SO}_3\text{H})_2$. Formed by boiling the trisulphonic acid with HOAc (Albrecht, A. 161, 134). Gives a blue colour with FeCl_3 .— $\text{K}_2\text{A}''\frac{1}{2}\text{aq}$.— $\text{Ph}_2(\text{CHS.O}_3)_2$, 8aq. Small needles.

Sulphydro-methane trisulphonic acid $\text{HS.C}(\text{SO}_3\text{H})_3$. Formed by boiling CS_2 or CSCl_2 with K_2SO_4 aq.— $\text{K}_2\text{A}'''\frac{2}{3}\text{aq}$: triclinic crystals. S. 2 at 12°. Gives a blue colour with FeCl_3 .— $(\text{NH}_4)_2\text{A}'''\text{aq}$. Thin plates.

SULPHYDRO-METHENYL-AMIDO-CRESOL

$\left[\begin{smallmatrix} 1 \\ 4 \end{smallmatrix} \right] \frac{1}{2} \text{C}_6\text{H}_4\text{Me}\begin{smallmatrix} \text{O} \\ \text{N} \end{smallmatrix} \text{C.SH}$. [217°]. Formed by heating benzene-azo-*p*-cresol with CS_2 at 200° (Jacobsen a. Schenke, B. 22, 3235). Needles.

SULPHYDRO - METHENYL - AMIDO - (α) -

NAPHTHOL $\text{C}_{10}\text{H}_7\begin{smallmatrix} \text{O} \\ \text{N} \end{smallmatrix} \text{C.SH}$. [above 220°]. Formed by heating an alcoholic solution of $\text{S}_2(\text{C}_{10}\text{H}_7\text{.NH}_2[1:2])_2$ with CS_2 (Jacobson, B. 21, 2624). Needles. Oxidised by K_2FeCy_4 to a crystalline disulphide.

Sulphydro-methenyl-amido-(β)-naphthol. [249°]. Formed by heating benzene-azo-(β)-naphthol with CS_2 at 250° (Jacobson, B. 21, 414). Needles, sl. sol. benzene. HClAq at 170° yields amido-(β)-naphthol. An alcoholic solution of iodine forms crystalline $(\text{C}_{10}\text{H}_7\begin{smallmatrix} \text{O} \\ \text{N} \end{smallmatrix} \text{C})_2\text{S}_2$.

SULPHYDRO - METHENYL - α - AMIDO-

NAPHTHYL MERCAPTAN $\text{C}_{10}\text{H}_7\begin{smallmatrix} \text{O} \\ \text{N} \end{smallmatrix} \text{C.SH}$. [above 240°]. Formed by heating α -naphthyl

thiocarbimide with S at 225°, and got also by the action of CS_2 on di-amido-di-naphthyl disulphide (Jacobson, B. 21, 2625; 24, 1406). Minute rosettes, sol. alcohol. Oxidised by K_2FeCy_4 to $(\text{C}_{10}\text{H}_7\begin{smallmatrix} \text{O} \\ \text{N} \end{smallmatrix} \text{C})_2\text{S}_2\text{—B'HgCl}_2$. [210°].

Sulphydro-methenyl-amido-(β)-naphthyl mercaptan [282°]. Formed by heating (β)-naphthyl thiocarbimide with S. Minute needles. Yields a methyl ether [74°], crystallising in needles.

SULPHYDRO - METHENYL - o - AMIDO-

PHENOL $\text{C}_6\text{H}_4\begin{smallmatrix} \text{O} \\ \text{N} \end{smallmatrix} \text{C.SH}$. *Thiocarbimido-phenol*. [196°]. Formed by boiling an alcoholic solution of o-amido-phenol for several days with CS_2 in a current of H as long as H_2S is given off (Dünner, B. 9, 465). Formed also by heating oxy-phenyl-thio-urea, and by heating o-oxy-phenyl-allyl-thio-urea with HCl at 130° (Von Chelmicki, J. pr. [2] 42, 442; B. 20, 177). Obtained also by adding dilute alcohol to a mixture of potassium xanthogenate and amido-phenol hydrochloride (Kalkhoff, B. 16, 1825). Needles (from water), sl. sol. cold water. Sol. NH_4Aq , crystallising therefrom unaltered.

Reactions.—1. Converted in o-amido-phenol by HClAq at 170°, and by NH_4Aq at 200°.—

2. Ac_2O yields $\text{C}_6\text{H}_4\begin{smallmatrix} \text{O} \\ \text{N} \end{smallmatrix} \text{C.SAc}$ [120°].—3. BzCl forms benzenyl-amido-phenol and $\text{C}_6\text{H}_4(\text{NHBz}).\text{OBz}$.—4. An alcoholic solution of iodine, added to its solution in NaOHAq , forms $(\text{C}_6\text{H}_4\begin{smallmatrix} \text{O} \\ \text{N} \end{smallmatrix} \text{C})_2\text{S}_2$ [110°], which is reconverted by hot dilute NaOHAq into sulphydro-methenyl-amido-phenol.—5. Boiling methyl-aniline forms a base (? $\text{C}_6\text{H}_4\begin{smallmatrix} \text{O} \\ \text{N} \end{smallmatrix} \text{C.NPhMe}$) which yields $\text{B'H}_2\text{PtCl}_6$.

Salt.— $\text{AgC}_6\text{H}_4\text{NSO}$. Amorphous.

Ethyl ether $\text{EtC}_6\text{H}_4\text{NSO}$. (c. 267°). Solid, melting below 35°; volatile with steam.

SULPHYDRO-METHENYL-AMIDO-PHENYL-

MERCAPTAN $\text{C}_6\text{H}_4\begin{smallmatrix} \text{O} \\ \text{N} \end{smallmatrix} \text{C.SH}$. [179°] (H.); [174°] (J. a. F.).

Formation.—1. By digesting o-amido-phenol with CS_2 (Hofmann, B. 20, 1789).—2. By heating $\text{C}_6\text{H}_4\text{.N}_2\text{C}_6\text{H}_5$ with CS_2 at 265° (Jacobson a. Frankenbacher, B. 24, 1403).—3. By heating phenyl thiocarbimide with sulphur.

Properties.—Needles or plates, v. sol. alcohol and ether. Forms B'HgCl_2 . Oxidised by $\text{K}_2\text{Cr}_2\text{O}_7$ to $(\text{C}_6\text{H}_4\begin{smallmatrix} \text{O} \\ \text{N} \end{smallmatrix} \text{C})_2\text{S}_2$, which yields $\text{B'K}_2\text{Cr}_2\text{O}_7$,

[180°]. MeI yields $\text{C}_6\text{H}_4\begin{smallmatrix} \text{O} \\ \text{N} \end{smallmatrix} \text{C.SMe}$ [52°], which forms $\text{B'H}_2\text{PtCl}_6$, crystallising in plates.

SULPHYDRO - METHENYL - BENZENYL -

THIO-AMIDOXIM $\text{C}_6\text{H}_5\text{C}\begin{smallmatrix} \text{O} \\ \text{N} \end{smallmatrix} \text{C.SH}$. [162°].

Formed by the action of CS_2 on an alkaline alcoholic solution of benzenyl-amidoxim (Crayen, B. 24, 388). Needles, nearly insol. water and cold alcohol. Conc. HClAq at 150° decomposes it into benzoic acid, CO_2 , NH_3 , H_2S , and S. NaOEt and EtI yield $\text{C}_6\text{H}_5\text{C}\begin{smallmatrix} \text{O} \\ \text{N} \end{smallmatrix} \text{CEt}$ [49°],

while benzyl chloride forms, in like manner, $C_6H_5.C \begin{smallmatrix} \text{N.S} \\ \text{N} \end{smallmatrix} > C.CHPh$ [79°].

SULPHYDRO - METHENYL - p - TOLYL - METHYLENETHIO-AMIDOXIM $C_6H_5.N_2S_2$ i.e.

$C_6H_5.Me.C \begin{smallmatrix} \text{N.S} \\ \text{N} \end{smallmatrix} > C.SH$. [166°]. Formed from CS_2 and tolyl-methenyl-amidoxim (Crayen, B. 24, 391). Crystals (from alcohol acidulated with HOAc), insol. water, sl. sol. ether. Forms salts with bases. p-Tolyl-methenyl-amidine forms the salt $C_6H_5.Me.C(NH_2):NHHA'$ [172°]. Boiling EtI and NaOEt yield $C_6H_5.Me.C \begin{smallmatrix} \text{N.S} \\ \text{N} \end{smallmatrix} > C.SET$ [87°].

SULPHYDRO - METHYL - GLYOXALINE

$C_6H_5SN_2$ i.e. $\begin{smallmatrix} CH.NMe \\ CH - N \end{smallmatrix} > C.SH$. [142°]. (c. 280°). Formed by boiling $CH(OEt)_2.CH_3.NH_2$ with methyl thiocarbimide, alcohol, and dilute (30 p.c.) H_2SO_4 (Wohl a. Marckwald, B. 22, 1354). Plates, v. sol. water, sol. alcohol.— B'_2PtCl_6 .— $B'AuCl_3$.— $C_6H_5AgSN_2$.— $B'MeI$. [148°]. Needles.

Methyl derivative $\begin{smallmatrix} CH.NMe \\ CH - N \end{smallmatrix} > C.SMe$.

Methylimidazolyl methyl sulphide. (225° uncor.). Formed by treatment with MeI and alkalis. Liquid, miscible with water, alcohol, and ether. Boiling dilute HNO_3 forms $C_6H_5.NO_2SN_2$ [85°], which yields $B'_2H_2PtCl_6$ [197°]. $C_6H_5SN_2.MeI$. [173°]. Needles, v. sol. Aq.

Reference. — OXY-SULPHYDRO-DI-METHYL-GLYOXALINE.

SULPHYDRO-DI-METHYL-PYRIDINE

$CS \begin{smallmatrix} CH:CMc \\ CH:CMc \end{smallmatrix} > NH$. [210°-215°]. Formed by heating oxy-di-methyl-pyridine with P_2S_5 at about 160° (Guthzeit a. Epstein, B. 20, 2113). Needles, v. sol. hot water and alcohol.

SULPHYDRO - METHYL - QUINAZOLINE.

Dihydride $C_6H_5 \begin{smallmatrix} CH_2.NMe \\ NH.CS \end{smallmatrix}$. [139°]. Formed by warming ω -oxy-tolyl-methyl-thio-urea with $HClAq$ (Söderbaum a. Widman, B. 22, 2935). Needles.— $B'_2H_2PtCl_6$. [195°].— $B'HAuCl_3$. [153°]. Minute needles.

SULPHYDRO-METHYL-QUINOLINE

$C_{10}H_7NS$ i.e. $C_6H_5 \begin{smallmatrix} CMc:CH \\ N=C.SH \end{smallmatrix}$. [253°]. Formed by heating (Py. 3,1)-oxy-methyl-quinoline with P_2S_5 (Roos, B. 21, 625). Small brown needles (from alcohol). Tastes bitter. Insol. cold water. Does not react with hydroxylamine and phenylhydrazine. H_2O_2 forms $C_{10}H_7N_2S_2$ [167°] crystallising from benzene in plates. EtI and alcohol at 100° form $C_6H_5 \begin{smallmatrix} CMc:CH \\ N=C.SET \end{smallmatrix}$, which is oily and yields $B'HI$ [240°] and $B'_2H_2PtCl_6$ $\frac{1}{2}$ aq crystallising in reddish prisms.

Sulphydro-methyl-quinoline

$C_6H_5 \begin{smallmatrix} C(SH):CH \\ N=CMe \end{smallmatrix}$. [187°]. Got by heating (Py. 1,3)-oxy-methyl-quinoline with P_2S_5 at 150° (Roos, B. 21, 629). Yellow prisms (from water). EtI and NaOEt yield $C_{10}H_7EtNS$ [58°].— $B'HCl$. [205°-210°] (Conrad a. Limpach, B. 21, 1972).

SULPHYDRO-METHYL-THIAZOLE. Di-

hydride $CHMe.S \begin{smallmatrix} CH_2 \\ CH - N \end{smallmatrix} > C.SH$. [82°]. Formed from β -bromo-propyl-amine hydrobromide, NaOHAq, and CS_2 (Hirsch, B. 23, 968). White needles, v. sol. hot water. Yields $C_6H_5.MeNS(SMe)$

(217°), $C_6H_5.MeNS(SET)$ (229°), and the propyl ether $C_6H_5.MeNS(SC_2H_5)$ (247°).

ψ -**SULPHYDRO-(α)-NAPHTHYL-METHYL-BIAZOLE** $O \begin{smallmatrix} CMc:N \\ CS - NC_6H_5 \end{smallmatrix}$. [86°]. Formed from acetyl (α)-naphthyl-hydrazine and $CSCl_2$ in $CHCl_3$ (Preund, B. 24, 4184). Yellow needles, v. e. sol. alcohol. The isomeride from (β)-naphthyl-hydrazine melts at 109°.

SULPHYDRO-PENTHAZOLE Dihydride

$CH_2 \begin{smallmatrix} CH_2.S \\ CH - N \end{smallmatrix} > C.SH$. [132°]. Formed by shaking γ -bromo-ethylamine hydrobromide with NaOHAq and CS_2 in the cold (Gabriel a. Lauer, B. 23, 92). Crystals, v. sol. hot water and alcohol, insol. acids, sol. NaOHAq. Bromine-water at 100° produces $CH_2(NH_2).CH_2.CH_2.SO_2H$.

ψ -**SULPHYDRO-PHENYL-AMIDIO-(α)-NAPHTHYL-THIOBIAZOLE** $C_6H_5.N_3S_2$ i.e. $S \begin{smallmatrix} C(NHPh):N \\ CS.N(C_6H_5) \end{smallmatrix}$. [255°]. Formed by mixing $NHPh.CS.NH.NHC_6H_5$ with $CSCl_2$ in benzene (Preund, B. 24, 4192). Colourless crystals, v. sol. acetone, sl. sol. alcohol.

ψ -**SULPHYDRO-PHENYL-METHYL-BIAZOLE** $O \begin{smallmatrix} CS.NPh \\ CMc:N \end{smallmatrix}$. [72°]. Formed from dichloro-phenyl-methyl-biazole dihydride and alcoholic ammonium sulphide (Freund a. Kuh, B. 23, 2837). Formed also from $NHAc.NHPh$ and $CSCl_2$ (Freund a. Goldschmidt, B. 21, 2456). Prisms (from alcohol). Yields phenyl thiocarbimide on distilling with P_2S_5 .

SULPHYDRO-PHENYL-GLYOXALINE

$C_6H_5.N_2S$ i.e. $\begin{smallmatrix} CH:CH \\ N:C(SH) \end{smallmatrix} > NPh$. [181°]. Formed by boiling $NHPh.CS.NH.CH_2.CH(OEt)_2$ with dilute H_2SO_4 (Wohl a. Marckwald, B. 22, 569, 1353). Needles (from hot water), v. sol. NaOHAq, insol. NH_3 Aq.—Salts: $C_6H_5AgN_2S$.— $B'_2H_2PtCl_6$: deep-red crystals.— $B'MeI$. [152°].

Methyl derivative $\begin{smallmatrix} CH:CH \\ N=C(SMe) \end{smallmatrix} > NPh$.

[54°]. Formed by treatment with alcoholic NaOH and MeI. White needles (from alcohol), insol. water.— $B'_2C_6H_5N_2O$.— $B'HNO_3$. Needles, v. e. sol. water.— $B'MeI$. [177°]. Crystalline rosettes (from water). Oxidised by dilute HNO_3 to a nitro-compound [116°].

ψ -**SULPHYDRO-PHENYL-DI-METHYL-PYRIDINE DICARBOXYLIC ETHER**

$CS \begin{smallmatrix} CMc:C(CO_2Et) \\ CMc:C(CO_2Et) \end{smallmatrix} > NPh$. [245°]. Formed by heating $CS \begin{smallmatrix} CMc:C(CO_2Et) \\ CMc:C(CO_2Et) \end{smallmatrix} > O$ with aniline and HOAc (Guthzeit a. Epstein, B. 20, 2112). Sulphur-yellow crystals (from alcohol).

ψ -**SULPHYDRO-PHENYL-NAPHTHYL-BIAZOLE** $O \begin{smallmatrix} CS.NC_6H_5 \\ CPh:N \end{smallmatrix}$. [164°]. Formed from $NHBz.NHC_6H_5$ and $CSCl_2$ in $CHCl_3$ (Preund, B. 24, 4186). Needles, v. sol. alcohol.

SULPHYDRO-PHENYL-QUINAZOLINE.

Dihydride $C_6H_5 \begin{smallmatrix} CH_2.NPh \\ NH.CS \end{smallmatrix}$. [197°]. Formed by warming ω -oxy-tolyl-phenyl-thio-urea with conc. $HClAq$ (Söderbaum a. Widman, B. 22, 1671). Needles.— $B'_2H_2PtCl_6$. [219°].— $B'HAuCl_3$. [197°]. Needles.

Reference. — OXY-SULPHYDRO-PHENYL-QUINAZOLINE.

DI-SULPHYDRO-DI-PHENYL-THIO-UREA.

Di-methyl derivative $\text{CS}(\text{NH.C}_6\text{H}_5.\text{SMe})_2$. [162°]. Formed by boiling [1:2] $\text{NH}_2.\text{C}_6\text{H}_5.\text{SMe}$ with CS_2 and solid KOH (Hofmann, *B.* 20, 1794). Prisms, v. sl. sol. alcohol. Forms, when heated, $\text{SCN.C}_6\text{H}_5.\text{SMe}$ (c. 270°).

 β -SULPHYDRO-PROPIONIC ACID

$\text{CH}_3(\text{SH}).\text{CH}_2.\text{CO}_2\text{H}$. Formed from β -iodopropionic acid and KSH . Got also by reducing sulphido-dipropionic acid (Lovén, *J. pr.* [2] 29, 376). Liquid, miscible with water, alcohol, and ether. Easily oxidised by air. CuSO_4 gives a pale-violet pp., but if not in excess it forms a yellow pp. of $\text{CH}_3(\text{SCu}).\text{CH}_2.\text{CO}_2\text{H}$ while $\text{S}(\text{C}_2\text{H}_5.\text{CO}_2\text{H})_2$ remains dissolved. $\text{Hg}(\text{S.C}_2\text{H}_5.\text{CO}_2\text{H})_2$. Scales. $\text{—Bi}(\text{S.C}_2\text{H}_5.\text{CO}_2\text{H})_3$.

Isomeric.—**THIOLACTIC ACID.**

SULPHYDRO - PROPYL - PHTHALIMIDE

$\text{C}_6\text{H}_5\text{O}_2.\text{N}.\text{CH}_2.\text{CH}_2.\text{CH}_2.\text{SH}$. [48°]. Formed by heating γ -bromo-propyl-phthalimide with KSHAq at 100° (Gabriel a. Lauer, *B.* 23, 88). Needles (from hot ligroin). Fuming HClAq at 180° forms phthalic acid and γ -amido-propyl mercaptan.

(Py. 3)-SULPHYDRO-QUINOLINE

$\text{C}_6\text{H}_4\text{<CH:CH}>\text{N:CSEt}$ [174°]. Formed by heating (Py. 3)-oxy-quinoline with P_2S_5 at 140° (Roos, *B.* 21, 620). Yellow plates (from dilute alcohol), insol. cold water, sol. acids and alkalis. Oxidised by H_2O_2 to $\text{C}_6\text{H}_3\text{N}_2\text{S}_2$ [137°]. EtI and alcohol at 100° form $\text{C}_6\text{H}_5(\text{SEt})\text{NHI}$ [154°], which yields $(\text{C}_6\text{H}_5(\text{SEt})\text{N})_2\text{PtCl}_6\text{aq}$, melting, when anhydrous, at 190°.

SULPHYDRO - THIAZOLE. Dihydride

$\text{CH}_2\text{S}>\text{CH}_2\text{N}>\text{O.SH}$. [107°]. Formed from bromo-ethyl-amine, NaOH , CS_2 , and alcohol (Gabriel, *B.* 22, 1152). Needles, sol. alcohol and hot water. Sol. alkalis. Bromine-water yields taurine. Alcohol, KOH and MeI form oily

$\text{C}_6\text{H}_4\text{<S}>\text{C.SMe}$ (217°), insol. alkalis but sol. acids.

Reference.—**OXY-SULPHYDRO-THIAZOLE.**

SULPHYDRO-ACETONE. The compound $\text{CH}_3.\text{O}(\text{SEt}).\text{CH}_2.\text{SEt}$ (170°) is formed by passing gaseous HCl into $\text{CH}_3.\text{CO}.\text{CH}_2.\text{SEt}$ mixed with mercaptan (Autenrieth, *B.* 24, 167).

α -SULPHYDRO- α -TOLUIC ACID. Methyl derivative $\text{CH}_3(\text{SMe}).\text{O}.\text{C}_6\text{H}_4.\text{CO}_2\text{H}$. [188°]. Formed by the action of conc. HClAq at 100° on the nitrile $\text{CH}_3(\text{SMe}).\text{C}_6\text{H}_4.\text{CN}$ (278°), which is got by dissolving thio-phthalimidine in alcoholic KOH and adding MeI (Day a. Gabriel, *B.* 23, 2484). Light oil.

SULPHYDRO-ISOVALERIC ACID

$\text{CHPr}(\text{SH}).\text{CO}_2\text{H}$. Formed from α -bromo-isovaleric acid and alcoholic KSH (Duvillier, *Bl.* [2] 30, 507).

SUPER. Use of this prefix applied to inorganic compounds. The prefix *super* is sometimes employed to denote the presence in compounds of relatively more of the characteristic negative element, or elements, than is found in the normal compounds of the same form. The prefix *per* is, however, much oftener used than *super*. It has been proposed by Mendeléeff to designate the oxides that belong to the same type as H_2O_2 ,

superoxides, to distinguish them from other peroxides (v. *Oxides*, vol. iii. p. 660).

M. M. P. M.

SUPERBIN. A poisonous substance contained in the root of *Gloriosa superba* (Warden, *Ph.* [3] 11, 495).

SYCOCERYL ALCOHOL $\text{C}_{22}\text{H}_{44}\text{O}$. [114°]. Occurs as acetyl derivative in the resin of *Ficus rubiginosa* (De la Rue a. Müller, *C. J.* 5, 62; Rennie a. Goyder, *C. J.* 61, 916). Thin crystals (from alcohol), insol. water and alkalis. BzCl yields a crystalline benzoyl derivative.

Acetyl derivative $\text{C}_{22}\text{H}_{42}\text{O}_2$. [121°]. Flat six-sided tablets, v. sol. hot alcohol, ether, and chloroform.

SYLVANE $\text{C}_8\text{H}_{16}\text{O}$. (63°). S.G. .887. Got by distilling pine-wood (Atterberg, *B.* 13, 879). Liquid, readily resinified. Oxidised by KMnO_4 to acetic acid. Not attacked by Na , alkalis, or Ac_2O . HCl passed into its ethereal solution forms a small quantity of $\text{C}_{13}\text{H}_{22}\text{O}$, a liquid boiling at 240°.

SYLVANE-ACETIC ACID v. **METHYL-FURFURYL-ACETIC ACID.**

SYLVANE-CARBOXY-ACETIC ACID v. **METHYL-CARBOXY-FURFURYL-ACETIC ACID** and **METHRONIC ACID.**

SYLVESTRENE v. **TERPENES.**

SYLVIC ACID $\text{C} = 78.7$ p.c. $\text{H} = 9.7$ p.c. [c. 162°]. $[\alpha]_D = -63^\circ$. This acid is obtained from colophony by repeated crystallisation from dilute alcohol, and is perhaps identical with abietic acid (Liebermann, *B.* 17, 1884; Haller, *B.* 18, 2166). By heating with HI and P it is converted into a terpene $\text{C}_{10}\text{H}_{18}$. Sylvic acid appears also to be formed by the action of gaseous HCl on an ethereal solution of dextro-pimaric acid (Vesterberg, *B.* 19, 2173). A sylvic acid $\text{C}_{20}\text{H}_{30}\text{O}_2$ is described by Maly (*Sitz. W.* 44, 121) as formed by adding dilute H_2SO_4 or gaseous HCl to a solution of abietic acid. Duvernoy (A. 148, 147) obtained a sylvic acid [129°] by distilling pimanic acid *in vacuo*.

Isosylvic anhydride $\text{C}_{10}\text{H}_{16}\text{O}_2$. (250° at 80 mm.). $\alpha_D = +63^\circ$. Got by distilling rosin *in vacuo* (Bischoff, *B.* 23, 1921). Colourless, brittle, microcrystalline substance, insol. water, v. sol. alcohol and ether. Isosylvic acid [62°] is ppd. on adding dilute HOAc to its solution in potash.

SYLVINOLIC ACID $\text{C}_{20}\text{H}_{30}\text{O}_2$? [130°]. Formed, together with sylvic acid, by saturating an alcoholic solution of abietic acid with HCl (Maly, *Sitz. W.* [2] 44, 121). Amorphous powder, v. sol. alcohol and ether.— CaA'' .— AgA'' : pulverulent pp., insol. NH_4Aq .

SYMBOLS. Symbols are employed to express the composition, and, as far as possible, the interactions, of compounds; v. *EQUATIONS, CHEMICAL* (vol. ii. p. 433), *FORMULAE* (vol. ii. p. 572), *ISOMERISM* (vol. iii. p. 79), and *cf. OPTICAL METHODS* (this vol. p. 258). M. M. P. M.

SYNANTHRENE $\text{C}_{14}\text{H}_{10}$. *Phosena*. Occurs in crude anthracene (Zeidler, *A.* 191, 298; cf. Barbier, *A. Ch.* [5] 7, 526). Yellowish-white plates. Yields a di-bromo-derivative $\text{C}_{14}\text{H}_8\text{Br}_2$ [175°], crystallising in minute yellow needles, sol. alcohol (difference from di-bromo-anthracene). Di-bromo-synanthrene is oxidised by CrO_3 and HOAc to a quinone (?) [240°–250°].

SYNANTHERIN v. **INULIN.**

SYNTHESIS. The building up of compounds from their elements, or from groups of elements.

SYNTONIN v. **PROTEIDS**.

SYRINGIN $C_{11}H_{16}O_6$. [191°]. *Dimethoxyconiferin*. Occurs in the bark of the lilac (*Syringa vulgaris*) and of the privet (*Ligustrum vulgare*) (Bernays, *J. pr.* 25, 121; Kromayer, *Ar. Ph.* [2] 108, 7; 109, 18, 216; 113, 19; Körner, *G.* 18, 215). White needles (containing aq.), v. sl. sol. cold water, v. sol. alcohol, insol. ether. Its aqueous solution is slightly bitter, is laevorotatory, and does not ppt. metallic salts. Conc. HNO_3 gives a blood-red solution. Conc. HCl aq. forms a colourless solution, turning blue, and finally giving a blue pp. Conc. H_2SO_4 gives a yellowish-green colour, changing to violet-brown and, on pouring into water, giving a bright-blue solution, which soon deposits an azure powder. Does not reduce Fehling's solution. Decomposed by emulsin into glucose and syringenin. $KMnO_4$ yields glucosyringic acid. CrO_3 forms glucosyringic aldehyde.

Syringenin $C_{11}H_{14}O_6$, *is.* [5:8:4:1]?

$C_6H_2(OMe)_2(OH).C_5H_8.OH$. Formed as above. Resembles coniferyl alcohol.

Glucosyringic acid $C_{13}H_{20}O_{10}$. [208°]. Formed as above. Needles or prisms (containing 2aq), sl. sol. cold water. Decomposed by dilute H_2SO_4 into syringic acid and glucose.

Syringic acid $C_7H_6(OH)(OMe)_2.CO_2H$. *Dimethyl derivative of gallic acid*. [202°]. Decomposes at 230° into CO_2 and the di-methyl derivative of pyrogallol.— BaA' , 3aq: four-sided tables.— MeA' aq. • [83°5']. Crystals, sol. Aq.

Methyl derivative $C_7H_6(OMe)_3.CO_2H$. [168°]. Needles. Yields $C_6H_3(OMe)_3$, when distilled with lime. Identical with the tri-methyl derivative of gallic acid.— MeA' . [82°5']. Needles.

Glycosyringic aldehyde $C_{13}H_{20}O_8$. [162°]. Colourless, silky needles. Decomposed by emulsin or dilute H_2SO_4 into glucose and syringic aldehyde. Yields a phenyl-hydrazide [156°] and a crystalline oxim.

Syringic aldehyde $C_7H_6O_4$, *is.* $C_6H_2(OH)(OMe)_2.CHO$. [111°5']. Small needles, smelling like vanillin. Turns brown in air. Reacts with phenyl-hydrazine, and combines with $NaHSO_3$.

T

TAIGUIC ACID v. **LAPACHIC ACID**.

TALOMUCIC ACID $C_8H_{10}O_8$. [168°]. $[\alpha]_D = +29.4^\circ$ at 20°. Formed from talonic acid and HNO_3 . (S.G. 1.15) (Fischer, *B.* 24, 3625). Minute plates, v. e. sol. cold water and warm alcohol; v. sl. sol. ether. Converted by HCl and HBr at 150° into dehydromucic acid. Yields a phenyl-hydrazide [185°–190°]. Pyridine at 150° forms mucic acid.— CaA' : crystalline powder.

TALONIC ACID $C_8H_{10}O_8$. Formed by heating galactonic acid with pyridine at 150° (Fischer, *B.* 24, 3622). Purified by means of its brucine salt. Syrup, very soluble hot alcohol. Laevorotatory. Yields a phenyl-hydrazide $C_8H_{10}O_8(N.H.Ph)$ [c. 155°].— CdA' aq. Needles (from alcohol), v. e. sol. water.—Brucine salt. [130°–133°]. Crystals, v. sol. water.

TAMPICIN $C_8H_{10}O_{11}$. [130°]. A neutral substance resembling convolvulin, occurring in *Tampica Jalap* (Spirigatis, *N. R. P.* 19, 452). Resin, v. sol. alcohol and ether. Converted by hot baryta-water into amorphous tampicic acid $C_8H_{10}O_{11}$. Boiling dilute acids resolve tampicin into glucose (3 mols.) and tampicolic acid $C_6H_{12}O_8$, which crystallises from dilute alcohol in minute needles and forms NaA' and EtA' , both being crystalline.

TANACETIN $C_{11}H_{16}O_6$. A bitter substance obtained from the leaves and flowers of the tansy (*Tanacetum vulgare*) (Leroy, *J. Chim. Med.* 21, 357; Leppig, *J.* 1882, 1175). Amorphous, sol. water and alcohol.

TANACETOGENIC ACID $C_6H_8O_8$. (114° at 15 mm.). Formed by the action of Br and (4 p.c.) $NaOHAq$ on tanaacetone (Semmler, *B.* 25, 3846). Oil, solidified below 0°.— AgA' .

TANACETONE $C_8H_{10}O$. (84°5' at 13 mm.). Occurs in oil of absinth, thuja, and sage, con-

stituting the chief part of absinthol, salviol, and (β)-thujol (Semmler, *B.* 25, 3343, 3350). Got from ethereal oil of *Tanacetum vulgare* by shaking with $NaHSO_3$, decomposing the crystalline product with Na_2CO_3 , and distilling with steam. Oil, v. sol. alcohol and ether. Does not reduce ammoniacal $AgNO_3$. Dextrorotatory; $\alpha = 38.5^\circ$ in a 20 cm. tube. S.G. 22 .913. $\mu_D = 1.450$.

Reactions.—1. Br and $KOHAq$ yield bromoform, hence it probably contains $CO.CH_3$.—2. Reduced in alcoholic solution by Na to tanaacetyl alcohol $C_{10}H_{16}O$ (93° at 13 mm.), S.G. 22 .925, $\mu_D = 1.4635$. This body does not combine with Br . With PCl_5 it yields tanaacetyl chloride (72° at 10 mm.).—3. Oxidised by $KMnO_4$ to Tanaacetketocarboxylic acid $C_{10}H_{14}O_6$. Needles [78°] (from ligroin) or plates [74°5'] (from water). Yields AgA' . Hydroxylamine yields $C_{10}H_{16}O_2(NOH)$ [103] when prepared from the needles and [169°] when got from the plates. The ketonic acid is oxidised by Br and $NaOH$ to tanaacetogen dicarboxylic acid $C_{10}H_{14}O_8$ [142°]. Plates (from water). This acid yields AgA'' while AqO yields the anhydride $C_{10}H_{12}O_8$ [55°], which gives isopropyl succinic acid [114°] when fused with potash.

Oxim $C_{10}H_{16}O_2.NOH$. [52°]. (186° at 20 mm.). Reduced in alcoholic solution by Na to tanaacetylamine $C_{10}H_{17}NH_2$ (80°5' at 14 mm.), S.G. 22 .874, $\mu_D = 1.462$, which yields $BHCl$, which when heated gives tanaacetene $C_{10}H_{16}$ (68° at 14 mm.), S.G. 22 .841, $\mu_D = 1.476$. Tanaacetone oxim may be converted by warming with alcohol and dilute sulphuric acid into the cymidine $C_6H_4(C_2H_5)(NH_2)Me$ [1:3:4], whence nitrous acid forms carvacrol.

TANACETOPHORONE $C_8H_{10}O$. (90° at 13 mm.). S.G. 22 .938. $\mu_D = 1.482$. Got by distilling tanaacetogen dicarboxylic acid with soda-lime

(Semmler, *B.* 25, 3850). An oil, smelling like camphor-phorone. Reacts with hydroxyl-amine.

TANGHININ $C_{27}H_{40}O_8$, 2aq. [182°].

$[\alpha]_D^{20} = -67^\circ$. Obtained from the kernels of *Tanghinia venenifera* of Madagascar (Arnaud, *C. R.* 108, 1255; 109, 701). Crystals (from alcohol), v. sl. sol. water, sl. sol. ether. Cardiac poison. Resinified by dilute acids. Baryta-water at 180° forms $C_{27}H_{40}O_{10}$.

TANNIN. TANNIC ACIDS. Under the above names are included a large series of compounds, occurring in the vegetable kingdom, of different constitutions, many of which have been very imperfectly studied. Their chief characteristics are their astringent taste and property of giving a dark-blue or green colouration with iron salts and a precipitate with a solution of gelatin. They all reduce solutions of the noble metals, and absorb oxygen in presence of alkalis. They are all aromatic derivatives, and yield on fusion with potash either pyrogallol or pyrocatechin. In some cases they have been synthetically prepared from these phenols and their derivatives, but in many cases the tannin appears to exist in the plant as a glucoside and attempts at a synthetic production have proved futile. Schiff (*B.* 15, 2590) prepared some of the tannins synthetically, and concluded that they were anhydro-compounds of gallic and protocatechuic acids respectively. Etti (*A.* 186, 332) and others have also, for example, synthetically prepared catechutannic acid by heating pyrocatechin with water or alkalis. Gallotannic acid was formerly believed to be a glucoside, but subsequent investigation showed that the amount of sugar present was variable, and Schiff (*A.* 170, 43) finally proved that, although existing in the plant as a very unstable glucoside, when it was isolated it had the constitution of an anhydro-acid formed by the removal of one molecule of water from two molecules of a tri-oxo-benzoic acid. He considered that in gallotannic acid the anhydroide was formed thus:— $C_6H_4(OH)_2.CO.O.C_6H_3(OH)_2.COOH$, whilst C. Etti, who has similarly investigated the tannins of the formulae $C_{12}H_{14}O_6$ and $C_{20}H_{22}O_8$, has proved that they also are not glucosides, and regards them as derivatives of a ketonic acid of the formula $C_6H_3(OH)_2.CO.C_6H_3(OH)_2.COOH$. It would appear, then, possible to define the tannic acids as mono-carboxyl acids formed by condensation from two molecules of poly-oxo-benzoic acids and which exist as unstable glucosides in plants. The ease with which gallotannic acid is hydrolysed renders it probable that the difference in constitution between Schiff's and Etti's formulæ does actually exist, and renders it possible to subdivide the tannins into these two groups so soon as the different tannins have been re-examined from this point of view. The ketonic character of the tannins was established by Etti through noting that they reacted with phenyl-hydrazine and hydroxylamine.

The origin of tannin in plants has given rise to much debate. According to Waage (*Ph.* 1890; *Phar. Centr.* 1891, 247) its formation is similar to that of the conversion of glucose into starch. The plant removes one molecule H_2O from glucose for reserve purposes, and if under favourable circumstances three molecules H_2O can be removed, a body having the composition

of a triketo-hexamethylene would be produced

$CH_2.COCH_2.COCH_2.CO$. This constitution corresponds to the secondary form of phloroglucin. It is probable that the phloroglucin combines with the CO_2 in the nascent state produced by the respiration of the plant, and is thus converted into a carboxylic acid (gallic acid); two molecules of this acid by the removal of another molecule of water would then form tannin. Light and chlorophyll are necessary for the production of tannin.

Westermaier (*B. B.* 1887, 127–143) showed that with experiments made with *Quercus pedunculata* the tannin migrates downwards through the bark and the pith. Starch is always present, and it is probable that the starch only migrates in the form of tannin. The leaves of *Rumex patens* and *Rheum raphaniticum* give both the starch and the tannin reactions. Schultz (*A. a.* 14, 525–526; *B. C.* 18, 137), by micro-chemical observations, also supports the view of Sachs and Heberland that the leaves of evergreens contain tannin as a winter reserve material. Tannin and starch only rarely occur simultaneously in the same cells. When the cells are rich in starch they contain a smaller amount of tannin, and *vice versa*.

In the case of leaves containing fatty oils and tannin, the cells which contain the oil are free from tannin, and cells containing no oil are free from starch. Kraus (*B. C.* 330–334) also notes that the formation of tannin in leaves depends on the presence of light and CO_2 , but believes that it acts more as a protecting agent either to prevent the plant from being eaten or rotting than as a reserve material. He points out that as fallen leaves contain as much tannin as they did during their best time of growth, the leaf tannin is of no value to the plant. Heckel a. Schlagdenhauffen (*Ph.* July 1892) note that the protecting leaf buds of certain species of gardenia contain a resinous substance which on analysis gives figures resembling cinchotannic acid. Both the gardenias and the cinchonas belong to the same order of plants (*cf.* Cross a. Bevan, *C. J.* 41, 106; Gardiner, *Ph.* [3] 14, 588; Braemer, *Les Tannoïdes*, Toulouse, 1890; Büsgen, *C. C.* 1890, 397).

Classification.—No satisfactory classification of these bodies exists. Wagner (*Fr.* 5, 1) divides them into pathological and physiological tannins. The former are chiefly glucosides, and precipitate gelatin, yield gallic acid when hydrolysed with dense sulphuric acid, and when heated alone form pyrogallol. The physiological tannins, on the other hand, form leather, and on distillation yield pyrocatechin. The old classification into iron-blueing and iron-greening tannins is found now to be untenable, as the presence of acids and salts modifies the colour which the tannins produce with $FeCl_3$, and the purity of many of the tannins examined by the earlier investigators cannot be guaranteed.

Reactions.—The oxidation of gallic and tannin acids by nitric acid of moderate dilution yields oxalic acid and two acids, probably tri-oxo-glutaric and tri-oxo-butyric. The acetyl-o-querctannic acid yields the same acids on oxidation (Böttger, *A.* 257, 248–252). Metallic Na does not reduce gallic acid in absolute alcohol,

but tannic acid similarly treated undergoes simple hydrolysis, the yield of gallic acid amounting to 60 p.c. of the weight of tannin. No reduction products could be prepared (Böttger, *A.* 258, 252-260). Ammonia and zinc dust at 60° convert both acids into benzoic acid. Dilute H_2SO_4 and Zn also form benzoic from gallic acid (Guignet, *C. R.* 113, 200-201).

The action of heat. Most tannins begin to blacken at 120°, and at 160° decomposition into metagallic acid, and either pyrogallol or pyrocatechin, takes place. Those which yield pyrogallol usually also form a 'bloom' on leather, and give a blue colour with FeCl_3 . This class includes galls, sumac, chestnut, and oak bark. The pyrocatechin-yielding tannins do not form a 'bloom' on leather, give green compounds with FeCl_3 , and include hemlock, catechu, rhatany, and mangrove (Trimble, *The Tannins*, 1892).

The products of the action of heat on the tannins are best obtained by allowing the heating to take place on the material suspended in glycerin (1 g. in 5 c.c. glycerin). After heating to 200° for 30 minutes, dilute with water, and extract with ether. The ethereal extract contains either pyrogallol or pyrocatechin. The tannin must be freed from gallic acid and catechin before subjecting it to this test by previous ether extraction of the aqueous solution.

The action of dilute acids. 2 p.c. absolute HCl at 100° in sealed tubes decomposes the tannins; insoluble ellagic acid, anhydrides, or phlobaphenes separate, and the filtrate contains gallic acid, glucose, and unaltered tannin. Glucose should be removed from the tannin by repeated lead acetate precipitation before this treatment, or the amount of glucose before and after hydrolysis may be determined by Fehling's solution (Wehmer a. Tollens, *A.* 243, 327).

The action of alkalis. The pyrocatechin-yielding tannins on heating with alkali yield protocatechuic acid, and either phloroglucin or acetic acid. The pyrogallol-yielding tannins form gallic and ellagic acids (20 g. with 150 c.c. of KHO solution, sp.gr. 1.2 for 3 hours are convenient quantities (Trimble, *The Tannins*)).

The tannins in the bark of oak, chestnut, horsechestnut, fir, &c., are precipitated in brominated condition by bromine water; tannin, sumach tannin, and oak wood tannin are not so precipitated (Böttger, *A.* 240, 330). From oak tannin, Böttger, by treating with acetic anhydride, has formed an acetyl-o-compound of the formula $\text{C}_{11}\text{H}_7\text{Ac}_2\text{O}_6$, and from it two bromo-derivatives $\text{C}_{11}\text{H}_5\text{BrAcO}_6$ and $\text{C}_{11}\text{H}_5\text{Br}_2\text{AcO}_6$ (*B.* 20, 761-766). A benzoyl-o-derivative has also been obtained from tannin by treatment with conc. NaOHAq and benzoyl chloride (Böttger, *A.* 254, 370). The same author has attempted to prepare cyanhydrins, but without success. Well-dried tannic acid heated with anhydrous HCN in sealed tubes yielded only an amide of gallic acid. Treated with hydroxylamine no oxim was formed, but only gallic acid (*A.* 259, 182-186). With pure tannin phenyl-hydrazine, however, forms derivatives which do not crystallise, CO_2 and N being evolved at the same time. The tannins experimented upon were extracts of sumach, divi divi, oak wood, oak bark and pine bark; the dry precipitates contained phenyl-hydrazine derivatives of tannic

and gallic acids, osazones of dextrose and levulose, and caramel (*A.* 259, 125-132; *A.* 258, 342).

Tannin solutions are very unstable, undergoing hydrolysis into gallic acid on standing. The hydrolysis into gallic acid is almost quantitative when the acid is dissolved in conc. H_2SO_4 and then water added (Böttger, *A.* 254, 373). When heated with KHSO_4 and glycerin to 119°-200° and the melt extracted with water, a residue is left soluble in absolute alcohol which contains two new acids of the composition $\text{C}_{11}\text{H}_7\text{O}_6\text{Ag}$ and called hydrotannic and isotannic acids respectively. The former, which is the less soluble in alcohol, forms with Ac_2O a tetra-acetyl-compound while the iso-acid forms a brown tri-acetyl-compound (*C. J.* 1892, 181).

Preparation of tannic acid for pharmaceutical purposes. Pelouze in 1834 first suggested the extraction of tannic acid from galls by percolation with ether, and this method is still in use. The powdered galls are placed in a closed percolator with commercial ether containing alcohol and water. The ethereal layer contains gallic and ellagic acids, together with resins and fats and a small portion of the tannic acid; the lower aqueous solution contains nearly pure tannic acid. The percolation is stopped when the lower layer ceases to increase in volume. The B. P. method consists in taking the damp galls, macerating with commercial ether, and expressing through muslin (Leconnet a. Dominé). The purest acid is obtained when 10 pts. powdered galls are allowed to stand two days covered in a percolator with a mixture of 12 pts. ether and 3 pts. alcohol. At the end of this time the percolation is commenced until 10 pts. are obtained. One-third its volume of water is then added, and the mixture well agitated. The aqueous layer contains nearly pure tannic acid, and is evaporated rapidly *in vacuo*. The commercial acid is known under the names of ether-tannin, alcohol-tannin, or water-tannin, according to the method of extraction adopted on a large scale.

Purification.—Petroleum ether percolation removes fat, wax, and some of the colouring matter. Solution in water removes resin, and, after decantation, sodium chloride precipitates the acid. Trimble adds lead acetate to the aqueous solution to precipitate colouring matter, filters, and extracts with acetic ether. The acid is re-dissolved in water, and extracted with ether to remove the last traces of gallic acid, and the aqueous solution finally dried *in vacuo*.

Detection.—1. Dilute H_2SO_4 or HCl precipitates conc. solutions.—2. FeCl_3 , a blue or green precipitate destroyed by long boiling, sol. weak mineral acids.—3. Lime-water precipitates the Ca salt. 4. Cinchonine sulphate precipitates white cinchonine tannate.—5. Gelatin forms leather and albumen also gives a precipitate. Alum and NH_4Cl render the precipitation more complete. 6. An alcoholic solution of thymol, followed by conc. H_2SO_4 , yields a rose-coloured turbid solution (pyrogallol violet; gallic acid gives no colour; Saul, *Ph.* [3] 17, 387).—7. Iodine in presence of neutral salts gives a purple colouration (Nasser). 8. Acetate of lead acidulated with acetic acid ppts. tannic and not gallic acid (Guyard, *Bl.* 2, 41, 336).—9. NH_4Cl and NH_3 give a white precipitate rapidly becoming red, gallic acid a red coloura-

tion only.—10. Cl water and NH_3 give a red colouration both with gallic and tannic acids.—11. K_2FeCy_4 gives a similar reaction (Rawson, *C. N.* 59, 52-53).—12. In plants, Moll (*A. a.* 12, 496) detects tannins micro-chemically by treatment with 7 p.c. copper acetate for some days, then cuts sections, treats with a drop of 0.05 p.c. ferric acetate, washes with water and then alcohol to remove chlorophyll, and mounts in glycerin and looks for blue or green stain.—13. KCN gives a green colouration with tannin and none with gallic acid.—14. $\text{K}_2\text{Cr}_2\text{O}_7$ gives a brown pp. with most tannins.—15. Saturated solutions of NaCl, CaCl_2 , KOAc, and a number of other salts ppt. tannins from solution.—16. Conc. H_2SO_4 dissolves the dry tannins with a yellow colour, and on heating forms dark-red rufigallic acid and then black metagallic acid.—17. HNO_3 forms a yellow colour, and finally oxidises them to oxalic acid.—18. As_2O_3 heated with the dry tannins converts most into ellagic acid.—19. Most tannins are ppd. by the alkaloids.

Estimation of tannic acid. The methods devised for the estimation of tannic acid in vegetable extracts are very numerous, and may be grouped under the following heads:—

1. Gelatin or hide-powder absorption.
2. Titration with permanganate.
3. Precipitation with metallic salts.
4. Methods not included in the above.

For details of these various processes, *vide* Proctor, *Textbook of Tanning*; Trimble, *The Tannins*; Thorpe's *DICTIONARY OF APPLIED CHEMISTRY*, and Rideal, *Chemical Notes on Modern Tanning*; *The Assay of Tanning Materials*; *Industries*, vol. xi. pp. 19, 139, 451. The two methods most generally employed are the hide-powder method and Löwenthal's permanganate process.

The hide-powder method is conducted as follows. A weighed quantity of the material is extracted with water and made up to a known volume. 100 c.c. of this solution is then evaporated, dried, and weighed to give the total solids present in the extract. Another portion of the same solution is agitated with, aspirated, or filtered through hide powder, and the total solids left in 100 c.c. of the solution again determined. The difference gives the quantity of tannic acid or matter which combines with gelatin per 100 c.c. of the solution (*Fr.* 24, 271).

The modified Löwenthal's process, which is now official in Germany, requires a standard solution of permanganate whose indigo value is known. A measured volume of the tannin solution, together with a known volume of indigo solution, is then titrated with the permanganate solution. Another equal volume of the tannin solution is then agitated with hide powder or shaken with a gelatin and alum solution and filtered, and the filtrate, after indigo solution of known amount has been added, is titrated with the permanganate solution. The difference in the quantity of permanganate consumed is a measure of the tannic acid present. The various tannins of commerce have different permanganate values; it is, therefore, necessary to standardise the permanganate for different tannin materials (Löwenthal, *Fr.* 16, 83; Kathreiner, *Fr.* 18, 118; Simaud, *Fr.* 22, 595; Schroeder, *Fr.* 25, 121).

Gallotannic acid $\text{C}_{12}\text{H}_{10}\text{O}_6$. Occurs in gall nuts and sumach.

Constitution.—

$\text{C}_6\text{H}_3(\text{OH})_2\text{CO}_2\text{O.C}_6\text{H}_3(\text{OH})_2\text{COOH}$ (Schiff, *A.* 170, 43; Paul & Kingzett, *C. J.* 33, 217).

Solubility.—Sol. acetone, glycerin, and oils; insol. CS_2 , CHCl_3 , petroleum, and C_6H_6 .

Compounds.—With gelatin contains 16.5 p.c. nitrogen = 84 p.c. tannin (Bötttinger, *A.* 244, 227). (For other nitrogen values of gelatin-tannin compounds in leather, *v.* Rideal & Trotter, *S. C. I.* 1891.) Penta-acetyl-compound $\text{C}_{30}\text{H}_{12}(\text{OAc})_5\text{CO}_2\text{O.C}_{30}\text{H}_{12}(\text{OAc})_5\text{COOH}$ [137°] (Bötttinger, *B.* 17, 1504).

Action of heat.—At 215° it forms pyrogallol, CO_2 , and a trace of metagallic acid $\text{C}_6\text{H}_3\text{O}_5$. Strong heating at 240°–250° forms chiefly metagallic acid (Pelouze, *A.* 10, 159). Cold HNO_3 forms oxalic, trioxylglutaric, and trioxylbutyric acids (Bötttinger, *A.* 257, 248). Boiling with KHO forms tannomelanic acid $\text{C}_{12}\text{H}_4\text{O}_5$; cold KHO and air form tannoxylic acid $\text{C}_{12}\text{H}_4\text{O}_6$ (Büchner, *A.* 53, 378). Hydrolysed by dil. H_2SO_4 to gallic acid. Ferments also form gallic acid (van Tieghem, *C. R.* 65, 1092).

Oak bark. Tannic acid $\text{C}_{12}\text{H}_{10}\text{O}_6$.

Preparation.—The bark is extracted with alcohol, and the extract agitated with acetic ether and ether. Evaporate off ether, separate the precipitate of ellagic acid, and from residue separate gallic acid from the tannic acid by acetic ether and ether.

Properties.—Reddish-white powder. Sol. alcohol and acetic ether. Sl. sol. ether and water. Heated to 130°–140°C. it forms an anhydride $\text{C}_{12}\text{H}_8\text{O}_5$, which is sl. sol. water; sol. alcohol and alkalis, and with conc. H_2SO_4 gives a second anhydride $\text{C}_{12}\text{H}_6\text{O}_{10}$. Heated with conc. HCl it evolves CH_3Cl , gives also the iodoform reaction. On dry distillation it forms pyrocatechin. Fused with KOH yields protocathecuic acid, pyrocatechol, and traces of phloroglucin (Etti, *M.* 1880, 262-278). When boiled with ether the above anhydrides form a third anhydride $\text{C}_{12}\text{H}_4\text{O}_{12}$ (*M.* 1883, 512). Other anhydrides analysed by Etti are $\text{C}_{10}\text{H}_{12}\text{O}_{11}$, $\text{C}_{10}\text{H}_{10}\text{O}_{10}$, $\text{C}_{10}\text{H}_8\text{O}_{13}$, and $\text{C}_{10}\text{H}_{12}\text{O}_{14}$. Forms two hydrates (Löwe, *C. J.* 40, 901).

Salts. With Ca, Ba, and Pb; analysed by Etti and Löwe (*l.c.*).

Derivatives.—Oak-red $\text{C}_{12}\text{H}_{10}\text{O}_6\frac{1}{2}\text{aq}$ (Grabowski, *A.* 145, 2); $\text{C}_{12}\text{H}_8\text{O}_5$ (Bötttinger, *A.* 240, 341). Bötttinger has prepared various bromo-, acetyl-, and benzoyl-derivatives (*l.c.*) (Rochleder, *A.* 63, 205; Bötttinger, *A.* 202, 270; *B.* 14, 1598; Löwe, *Fr.* 20, 210; Etti, *M.* 4, 514; Grabowski, *A.* 145, 2).

Frazitannic acid $\text{C}_{28}\text{H}_{22}\text{O}_{14}$. In ash-leaves. Forms an anhydride $\text{C}_{28}\text{H}_{18}\text{O}_{13}$, a benzoyl-compound $\text{C}_{28}\text{H}_{22}\text{O}_{13}(\text{OBz})_4$, an acetyl-compound $\text{C}_{28}\text{H}_{22}(\text{OAc})_4\text{O}_{13}$, a bromoacetyl-compound $\text{C}_{28}\text{H}_{22}(\text{OAc})_4\text{Br}_2\text{O}_{13}$, and a similar nitro-compound. On heating with $\text{Ba}(\text{OH})_2$ it forms protocathecuic acid and other products. On heating to 100° it loses 1 mol. H_2O , forming an anhydride $\text{C}_{28}\text{H}_{20}\text{O}_{13}$ (Gintl & Reinitzer, *M.* 3, 745 *et seq.*).

The following table gives the source of the principal tannins which have been investigated, and references to the papers in which a description will be found.

Plant	Part	Name	Formula	Per cent.	References
<i>Æsculus Hippocastanum</i>	Nearly all parts	Horsechestnut tannin	$C_{28}H_{24}O_{12}$	—	Rochleder, <i>Sitz. B.</i> 53 [2] 473; 54 [2] 609
<i>Æsculus Hippocastanum</i>	Juice of berries	Rhamnotannic acid	$C_{28}H_{24}O_{12} \cdot H_2O$	—	Rochleder, <i>Z.</i> 1867, 84

S. R.

TANSY OIL. The essential oil, obtained by distillation of the tansy (*Tanacetum vulgare*), contains 1 p.c. of a terpene $C_{10}H_{16}$ (155° – 160°), 26 p.c. of an alcohol $C_{10}H_{18}O$, and 70 p.c. of 'tanacetyl hydride' $C_{10}H_{16}O$ (Bruylants, *J. Ph.* [4] 28, 893; B. 11, 449; cf. Persoz, *C. R.* 8, 433). Tanacetyl hydride $C_{10}H_{16}O$ (195° – 196°), S.G. 4.918, V.D. 5.1, is converted by H_2SO_4 into cymene. It reduces ammoniacal $AgNO_3$, forming a mirror. $NaHSO_4$ forms crystalline $C_{10}H_{16}NaSO_4$. Split up by water into the parent substances.

TANTALATES v. TANTALUM, ACIDS OF, AND THEIR SALTS. p. 639.

TANTALUM. Ta. At. w. c. 182 (exact value not known). Mol. w. not known. Ta has not been isolated.

Occurrence.—Tantalates occur in a few rare minerals, generally associated with niobates; *tantalite* contains from 85 to 75 p.c. Ta_2O_5 , *columbite* from 13 to 86 p.c., *ytrotantalite* from 6 to 47 p.c., and a mineral from Western Australia, recently analysed and called *stibio-tantalite*, c. 52 p.c. Ta_2O_5 (Goyder, *C. J.* 68, 1076).

History.—A short account of the researches that led to the identification of two distinct oxides in *tantalite* is given in the article Niobium (vol. iii. p. 505). Marignac (*C. R.* 60, 234, 1355) gave the formula Ta_2O_5 to oxide of Ta, which had been represented by Rose as TaO_2 . Deville determined the V.D. of the chloride, and deduced the molecular formula $TaCl_5$ (*C. R.* 56, 891). By heating Na_2TaF_6 with Na, H. Rose (*P.* 99, 69) obtained a black powder, probably a mixture of Ta and oxides of Ta. Berzelius (*P.* 4, 6) also obtained very impure Ta; Marignac (*Ar. Sc.* 1868) failed to isolate approximately pure metal.

Preparation of impure Ta.—Very finely-powdered *tantalite* is fused with three times its weight of $KHSO_4$ in an iron or platinum crucible, until completely dissolved. After cooling, the fused substance is powdered and treated with boiling water, whereby sulphates of K, Fe, and Mn are dissolved out; the insoluble portion is washed, and then digested with yellow ammonium sulphide, whereby sulphides of Sn and W are dissolved, and FeS remains mixed with Ta_2O_5 and Nb_2O_5 . The residue is washed thoroughly, and digested with $HClAq$ to remove FeS, and the portion insoluble in $HClAq$ is thoroughly washed with boiling water until it is white. The mixture of Ta_2O_5 and Nb_2O_5 thus obtained is dissolved in $HFAq$ in a platinum dish, the solution is heated to boiling, and a quantity of KHF_4 is added equal to one-fourth of the weight of mixed Ta_2O_5 and Nb_2O_5 used; the liquid is evaporated until 1 g. of the mixed oxides is present in about 7 c.c. and allowed to cool; the prismatic crystals of K_2TaF_7 , that separate are washed with cold water until the washings give a yellow pp., without any shade of red, after standing for two hours with tincture of galls. The K_2TaF_7 thus obtained is heated, in a platinum dish, with rather more than its weight of pure conc. H_2SO_4 , whereby $KHSO_4$, HF, and Ta_2O_5 are formed; the HF is removed by heat, and the $KHSO_4$ by repeated washing with water (Berzelius, *P.* 4, 6; cf. H. Rose, *P.* 144, 64, 72).

Lawrence Smith (*Am.* 5, 44) recommends to warm 5 g. of very finely powdered *tantalite*, dried at 150° , in a platinum basin with a little water and 8 to 10 c.c. very conc. $HFAq$, to filter when reaction is completed, add a little water to the filtrate and evaporate nearly to dryness, to warm with excess of conc. pure H_2SO_4 , and, after the acid has been almost wholly removed by heating, to place the residue in c. 500 c.c. dilute HNO_3Aq (*L. M.*, *C. N.* 51, 289, 304), and boil until Ta_2O_5 and Nb_2O_5 are ppd. By dissolving in $HFAq$, adding KHF_4 , and proceeding as described above, Ta_2O_5 is obtained free from Nb_2O_5 .

The pure Ta_2O_5 obtained by one of the preceding methods is dissolved in $HFAq$, in a platinum vessel, the solution is heated to boiling, and 70.8 pts. by weight of KHF_4 are added for 100 pts. Ta_2O_5 used. The solution is evaporated and allowed to cool; the crystals of K_2TaF_7 are washed with a little cold water, dried, mixed with c. half their weight of potassium, and heated in an iron crucible, the mixture of K_2TaF_7 and K being covered with KCl. The contents of the crucible, after cooling, are added, little by little, to water; the black powder that separates is washed with water, and then with dilute alcohol and dried (Berzelius, *P.* 4, 6). The black powder is probably a mixture of Ta and oxides of the metal. Berzelius found that 100 pts. took up 17 pts. O when heated in air, 100 pts. pure Ta require 22 pts. O to form Ta_2O_5 . H. Rose (*P.* 99, 69) obtained a black powder—probably Ta mixed with oxides—by reducing Na_2TaF_6 by heating with sodium.

Properties and Reactions.—The black powder obtained by Rose was a good conductor of electricity; it glowed when heated in the air, and slowly formed Ta_2O_5 ; it was insoluble in acids, except in $HFAq$, by which it was slowly dissolved; heated in a stream of Cl it burnt to $TaCl_5$. Oxidation was effected by molten alkalis or alkali carbonates. The S.G. of a specimen containing c. 40 p.c. acid sodium tantalate was c. 10.8.

The at. w. of Ta was determined by Marignac (*A.* 140, 153; *Suppl.* 4, 351 [1865]) by decomposing K_2TaF_7 and $(NH_4)_2TaF_7$ by H_2SO_4 , and determining the quantities of Ta_2O_5 and K_2SO_4 produced. The values obtained varied from 180.1 to 185.2. H. Rose in 1856 (*P.* 99, 80) analysed $TaCl_5$ by decomposing by water, ppg. $Ta_2O_5 \cdot xH_2O$ by NH_3Aq , and estimating Cl in the filtrate. His results showed marked discrepancies.

Ta is metallic in its physical properties, so far as may be judged from the impure specimens that have been prepared. Ta_2O_5 dissolves in $HFAq$, probably forming TaF_5 . No salts are known to be formed by replacing the H of an oxyacid by Ta. In all the salts of Ta that have been isolated, other than the haloid compounds, Ta forms part of the negative radicle. Ta is the fifth member of the even-series family of Group V; it is closely related to Nb, and less closely to N, P, V, As, Sb, Bi, Er, and Bi. The only compound of Ta whose V.D. has been determined is $TaCl_5$; in this molecule the atom of Ta is pentavalent (v. NITROGEN GROUP OF ELEMENTS, vol. iii. p. 571).

Detection and Estimation.—Tantalum com-

pounds form potassium tantalate when fused with KOH, and the fused mass dissolves in water. The product obtained by fusion with NaOH dissolves in water to a clear liquid only after NaOH has been removed by washing, as sodium tantalate is insoluble in much NaOH.Aq. Addition of acid to an aqueous solution of an alkali tantalate, followed by boiling, ppt. $Ta_2O_5 \cdot xH_2O$ more or less completely. By adding HCl.Aq to a solution of an alkali tantalate, and placing zinc in the solution, no blue colour is produced (cf. NIONIUM, DETECTION OF, vol. iii. p. 506). According to Levy (C. R. 103, 1074), an amethyst colour, is produced by adding a very small quantity of Ta_2O_5 to a solution of resorcin in H_2SO_4 .Aq. Ta is estimated as Ta_2O_5 ; the process is sufficiently indicated under *Preparation*.

Tantalum, acids of, and their Salts. Ta_2O_5 reacts with molten alkalis, and alkali carbonates, to form salts which may be regarded as derived from various hydrates of Ta_2O_5 . Two hydrates are obtained, $Ta_2O_5 \cdot 2H_2O$ and $2Ta_2O_5 \cdot 3H_2O$, by decomposing $TaCl_5$ by a little water, and by fusing Ta_2O_5 with $KHSO_4$ and washing with water (v. TANTALUM, OXIDES AND HYDRATED OXIDES OF, p. 640). The first of these hydrates may be called *pyrotantallic acid* $H_4Ta_2O_9$, corresponding with $H_3P_4O_{13}$; and the second may be formulated $H_5Ta_2O_{10}$. The tantalates that have been examined do not seem to be derived from either of these compounds, but from the hypothetical acids $HTaO_3$, corresponding with HPO_3 and HNO_3 , and $H_2Ta_2O_{10}$ ($= 3Ta_2O_5 \cdot 4H_2O$). Tantalates are not produced by neutralising $Ta_2O_5 \cdot xH_2O$, but by fusing Ta_2O_5 with alkalis, or by double decomposition from alkali salts.

TANTALATES. The tantalates belong to the form $\alpha Ta_2O_5 \cdot yMO$, where $M = (NH_4)_2, Mg, Hg, K, Ag, \text{ or } Na$; of those that have been fairly fully examined, some correspond with the metaphosphates and meta-niobates MXO_3 , and others belong to the more complex form $M'_2Ta_2O_{10}$. Some of the alkali tantalates dissolve slightly in water, the other tantalates are insoluble. *Fluotantalates* and *fluoxytantalates* are also known (v. *infra*). The tantalates have been investigated chiefly by H. Rose (P. 100, 417) and Marignac (Bl. [2] 6, 111, 118).

Ammonium tantalate. A pp. is obtained by adding NH_4Cl to solution of $Na_2Ta_2O_{10} \cdot xH_2O$, but the composition of the pp. is not known with certainty.

Magnesium tantalate. By adding $MgSO_4$.Aq to solution of $Na_2Ta_2O_{10} \cdot xH_2O$ a crystalline pp. was obtained which, after drying at 100° , had the composition $Mg_2Ta_2O_{10} \cdot 9H_2O$. A crystalline Mg tantalate was obtained by Joly (C. R. 81, 266, 1266) by fusing Ta_2O_5 with $MgCl_2$.

Mercurous tantalate. A brown, amorphous compound, perhaps $Hg_2Ta_2O_{10} \cdot xH_2O$, is formed by adding $HgNO_3$.Aq to solution in water of $Na_2Ta_2O_{10} \cdot xH_2O$.

Potassium tantalates. (1) $K_2Ta_2O_{10} \cdot 16H_2O$; this salt is obtained by fusing Ta_2O_5 with KOH, dissolving in water, and crystallising. (2) $KTaO_3$: this salt, *potassium metatantalate*, is formed by heating the other tantalate, alone or with $(NH_4)_2CO_3$, and then treating with water.

Silver tantalate. The yellowish white pp.

obtained by adding solution of a salt of Ag to solution of $Na_2Ta_2O_{10} \cdot xH_2O$, and drying at 100° , has the composition $Ag_2Ta_2O_{10} \cdot 3H_2O$.

Sodium tantalates. The *meta-salt* $NaTaO_3$ is obtained by fusing Ta_2O_5 with Na_2CO_3 , and washing with water. A salt of the composition $Na_2Ta_2O_{10} \cdot xH_2O$ ($x = 25$ and 30) is prepared by fusing Ta_2O_5 with NaOH, dissolving in water, and crystallising.

FLUOTANTALATES. (*Tantalifluorides*.) These salts may be regarded as compounds of TaF_5 with metallic fluorides, or as metallic derivatives of the hypothetical acid H_2TaF_4 ; they are prepared by dissolving Ta_2O_5 in HFAq, adding metallic fluorides, and crystallising; some of them are formed by dissolving Ta_2O_5 and a metallic oxide in HFAq (Marignac, A. Ch. [4] 9, 276; Berzelius, P. 4, 6).

Ammonium fluotantalate $(NH_4)_2TaF_6$, is obtained by evaporating a solution of NH_4F in solution of TaF_5 in HFAq, and evaporating; the salt is crystalline and easily soluble in water.

Copper fluotantalate $CuTaF_6$, forms blue, deliquescent, rhombic prisms; it is prepared by dissolving CuO and Ta_2O_5 in excess of HFAq, and evaporating.

Potassium fluotantalate K_2TaF_6 , forms white needles by dissolving KHF_4 in solution of Ta_2O_5 in HFAq, evaporating, and crystallising from hot water. The salt is very slightly soluble in cold water, but dissolves easily in hot water. On long boiling, K_2TaF_6 .Aq gives a white pp., probably having the composition $K_2Ta_2O_{10}F_{14}$ ($= 2TaF_5 \cdot Ta_2O_5 \cdot 4KF$). By dissolving K_2TaF_6 in warm 4 p.c. H_2O .Aq with a little HFAq and allowing to cool, Piccini (Zeit. für anorg. Chemie, 2, 21) obtained crystals of the *fluoxytantalate* $K_2TaO_5F_3 \cdot H_2O$ ($= TaO_5F_3 \cdot 2KF \cdot H_2O$).

Sodium fluotantalate $Na_2TaF_6 \cdot H_2O$; obtained, as white crystals, by dissolving $Na_2Ta_2O_{10}$ in HFAq, evaporating, and drying at 100° the salt that separates.

Zinc fluotantalate $ZnTaF_6 \cdot 7H_2O$; a deliquescent salt, obtained by dissolving ZnO and Ta_2O_5 in excess of HFAq and crystallising.

Tantalum, alloys of. By heating K_2TaF_6 with Al, and washing with HCl.Aq, Marignac (P. 100, 145) obtained a grey powder, S.G. 7.02. By heating to whiteness, in a carbon crucible, a mixture of Ta_2O_5 and iron filings, an alloy of Ta and Fe was obtained resembling pig iron (Gahn, Berzelius A. Eggertz, S. 16, 437).

Tantalum, bromide of, $TaBr_5$. A yellowish, crystalline compound, obtained by heating a mixture of dry Ta_2O_5 and Cl in vapour of Br, and removing excess of Br by a long-continued stream of dry CO_2 ; decomposed by water to HBr .Aq and $Ta_2O_5 \cdot xH_2O$ (H. Rose, P. 90, 456; 99, 76). The conditions of preparation are similar to those in making $TaCl_5$ (q. v.).

Tantalum, carbide of. By heating TaN (v. TANTALUM NITRIDE) with C to the melting-point of steel, N is given off and the nitride is partly converted into brass-yellow coloured TaC_2 (Joly, Bl. [2] 25, 206).

Tantalum, carbonitride of. Joly (Bl. [2] 25, 206) obtained a substance, to which he gave the formula $10TaC.TaN$, by very strongly heating a mixture of Ta_2O_5 with C and soda.

Tantalum, chloride of, $TaCl_5$. Mol. w. c. 359 (not determined with great accuracy, as at. w. of Ta is doubtful). V.D. 185 at 360° (Deville a. Troost, *C. R.* 64, 294). Melts at 211° , and boils at 242° at 753 mm. pressure (D. a. T., *l.c.*). Only one chloride of Ta has been isolated.

Preparation.—About 5 g. pure dry Ta_2O_5 is mixed with a considerable excess of dry sugar or starch, and the mixture is completely charred by heating in a closed crucible; the charred mass is broken into small pieces, which are heated to redness and placed, while red hot, in a rather wide tube of hard glass that is quickly heated to redness while a stream of thoroughly dried CO_2 is passed through it as long as any trace of moisture is given off from the contents of the tube; the tube is then allowed to cool, the current of dry CO_2 being maintained; when the tube is cold a stream of dry Cl is passed through it, and when every part of the apparatus is filled with Cl (but not until then) the contents of the tube are heated. $TaCl_5$ forms immediately behind the carbonaceous matter, as a pale-yellow solid; when the reaction has entirely ceased and CO is no longer evolved, the $TaCl_5$ may be sublimed into another part of the tube, a plentiful stream of dry Cl being maintained during the process. If sublimation is attempted before the whole of the Ta_2O_5 has been chlorinated, a part of the $TaCl_5$ is decomposed by the CO, with re-formation of Ta_2O_5 . If there should be any air in the tube during the process a white sublimate is formed which is probably an oxychloride (H. Rose, *P.* 90, 456; 99, 75). Should the Ta_2O_5 used contain any WO_3 , the sublimate obtained is reddish; by gently heating, the greater part of the red $WOCl_3$ may be removed, as it is more volatile than $TaCl_5$.

Demarçay obtained $TaCl_5$ by passing vapour of CCl_4 over Ta_2O_5 heated to redness (*C. R.* 104, 11).

Properties and Reactions.—Pale-yellow prismatic needles, melting at 211° , and boiling at 242° under the pressure of 753 mm.; begins to vaporise at 144° ; V.D. 185 at 360° (Deville a. Troost, *C. R.* 64, 294). Decomposes in ordinary air, giving off HCl and becoming covered with a crust of crystalline Ta_2O_5 . Decomposed entirely by water to $HClAq$ and $Ta_2O_5 \cdot xH_2O$. Conc. H_2SO_4 causes evolution of HCl, and forms a somewhat turbid solution from which $Ta_2O_5 \cdot xH_2O$ separates on boiling; by adding water to this solution, and boiling, the whole of the Ta is precipitated as $Ta_2O_5 \cdot xH_2O$. Conc. $HClAq$ reacts similarly to H_2SO_4 , but only a portion of the $Ta_2O_5 \cdot xH_2O$ is pptd. on adding water and boiling. $TaCl_5$ is partly dissolved by heating with $KOHAq$. $TaCl_5$ is soluble in absolute alcohol; H_2SO_4Aq does not ppt. $Ta_2O_5 \cdot xH_2O$ from this solution.

No double compounds of $TaCl_5$ with KCl or NaCl—similar to those of TaF_5 —have been obtained.

Tantalum, fluoride of. $Ta_2O_5 \cdot xH_2O$ dissolves in $HFAq$; neither boiling, nor adding H_2SO_4Aq to the solution, ppts. Ta_2O_5 . The solution in $HFAq$ gives off vapours on evaporation that probably contain TaF_5 ; by evaporating at a low temperature, Rose obtained crystals that dissolved easily in water, and were partly vaporised when heated, leaving some Ta_2O_5 (*P.* 90, 456;

99, 75). By evaporating *in vacuo* a solution of $Ta_2O_5 \cdot xH_2O$ in $HFAq$, Marignac obtained a white amorphous mass—probably an oxyfluoride—and then small crystals that were likely TaF_5 .

TaF_5 combines with some metallic fluorides, forming *fluotantalates* (*q.v.*, p. 639).

Tantalum, haloid compounds of. The only haloid compounds of Ta that have been isolated are $TaCl_5$ and $TaBr_5$. The former has been gasified, and the formula is molecular. TaF_5 also probably exists in solution of $Ta_2O_5 \cdot xH_2O$ in $HFAq$. There is no reaction between I and Ta_2O_5 mixed with C even at a very high temperature. $TaCl_5$ and $TaBr_5$ are readily decomposed by water, with formation of $Ta_2O_5 \cdot xH_2O$ and $HXAq$. Double compounds of TaF_5 with some metallic fluorides are known; they belong to the form M_2TaF_7 (*v.* FLUOTANTALATES). Oxyhaloid compounds probably exist, but none has been isolated with certainty.

Tantalum, nitrides of. $TaCl_5$ absorbs NH_3 at the ordinary temperature; by heating the product in NH_3 , Joly (*Bl.* [2] 25, 206) obtained an amorphous, yellow solid, to which he gave the formula Ta_3N_5 . By heating this yellow solid to redness in very dry NH_3 , a black solid was obtained which, after washing with water and drying, had the composition TaN . This black solid conducts electricity; heated in air it burns to Ta_2O_5 ; NH_3 is given off by the action of molten KOH; it is insoluble in acids, except in a mixture of $HFAq$ and HNO_3Aq (Joly, *l.c.*; cf. H. Rose, *P.* 100, 166).

Tantalum, nitrocarbide of; v. TANTALUM CARBONITRIDE, p. 639.

Tantalum, oxides and hydrated oxides of. The oxide Ta_2O_5 has been isolated, and also a hydrate of this oxide $Ta_2O_5 \cdot 2H_2O$, and probably also another hydrate $2Ta_2O_5 \cdot 3H_2O$. The existence of another oxide, TaO_3 , is doubtful.

TANTALUM PENTOXIDE Ta_2O_5 . (*Tantallic anhydride. Tantallic oxide.*) The preparation of this compound from *tantalite* is described at the beginning of this article under *Preparation of tantalum* (p. 638). Ta_2O_5 is also obtained by decomposing $TaCl_5$ by water, or by adding H_2SO_4Aq to solution of a tantalate and boiling, and then heating the $Ta_2O_5 \cdot xH_2O$ thus pptd. Ta_2O_5 is a white powder; it has not been fused; by heating with boric acid or microcosmic salt in a porcelain oven it is obtained in rhombic prisms (Ebelmen, *A. Ch.* [3] 33, 34; Nordenskjöld a. Chydenius, *J.* 1860. 145). S.G. c. 7.6 (Marignac, *Ar. Sc.* 1868; Deville, *C. R.* 56, 894). Ta_2O_5 is insoluble in acids except $HFAq$; after being very strongly heated, it is insoluble in $HFAq$. Ta_2O_5 dissolves in molten alkalis, also in molten $KHSO_4$ (*v.* TANTALATES, p. 639).

HYDRATES OF TANTALUM PENTOXIDE. By decomposing $TaCl_5$ by water, $Ta_2O_5 \cdot xH_2O$ is obtained, which, after very thorough washing with water, then with NH_3Aq to remove adhering HCl, and finally with water, and drying at 100° , gives off from 6 to 7.8 p.c. water when heated to redness. The formula $2Ta_2O_5 \cdot 3H_2O$ requires 5.7 p.c. H_2O , and the formula $Ta_2O_5 \cdot H_2O$ requires 7.5 p.c. H_2O . It is doubtful whether one or more than one definite hydrate exists in this pp. When SO_3 is passed into a solution of $Na_2Ta_2O_7$, a pp. of $Ta_2O_5 \cdot xH_2O$ is obtained, which, when

thoroughly washed and dried at 100°, is said to be $\text{Ta}_2\text{O}_5 \cdot 2\text{H}_2\text{O} = \text{H}_2\text{Ta}_2\text{O}_7$ (H. Rose, P. 100, 417). Strong acids, such as H_2SO_4 , HNO_3 , and HCl , ppt. $\text{Ta}_2\text{O}_5 \cdot x\text{H}_2\text{O}$ apparently in combination with the acid used as precipitant from solutions of alkali tantalates; weak acids ppt. insoluble alkali tantalates.

TANTALUM DIOXIDE Ta_2O_5 . (*Tantalum tetroxide* [Ta_2O_5].) The isolation of this oxide is doubtful. Berzelius obtained a brown powder by heating Ta_2O_5 to redness in a carbon crucible; it was not dissolved by any acids, not even by a mixture of HNO_3 and HFAg ; when strongly heated in air it gave Ta_2O_5 (P. 4, 20).

Tantalum, oxyfluoride of. The white powder formed by decomposing K_2TaF_6 by boiling water may be an oxyfluoride, according to Marignac (A. Ch. [4] 9, 276).

Tantalum, salts of. No salt has been isolated by replacing the H of acids, except HCl and HF , by Ta. When alkali tantalates are decomposed by strong acids such as HCl , HNO_3 , or H_2SO_4 , the ppd. $\text{Ta}_2\text{O}_5 \cdot x\text{H}_2\text{O}$ retains some of the acid used as precipitant; compounds of Ta_2O_5 with these acids are perhaps formed.

Tantalum, sulphide of. By strongly heating Ta_2O_5 in CS_2 vapour, also by heating to redness a mixture of vapour of TaCl_5 and H_2S , a yellowish black solid is obtained, which has the composition Ta_2S_5 , according to Berzelius (P. 4, 6; v. also H. Rose, P. 99, 575). Roasted in air, this solid gives Ta_2O_5 ; heated in Cl_2 it produces TaCl_5 and S_2Cl_2 ; conc. HNO_3 oxidises it to $\text{Ta}_2\text{O}_5 \cdot x\text{H}_2\text{O}$ and H_2SO_4 to Ta_2O_5 . Ta_2S_5 does not combine with alkali sulphides (R., l.c.); fused with KOH , it forms K_2S and potassium tantalates. M. M. P. M.

TARCHONYL ALCOHOL $\text{C}_{20}\text{H}_{40}\text{O}$ (?). Obtained from the leaves of *Tarchonanthus camphoratus* by extracting with alcohol (Canzoneri a. Spica, G. 12, 227). Silvery scales, insol. water and ether. Converted by PCl_5 into a chloride [70°] crystallising in small plates (from alcohol).

TARCONINE v. vol. iii. p. 496.

TARNINE v. vol. iii. p. 497.

TARTARIC ACID $\text{C}_4\text{H}_4\text{O}_6$, i.e.

$\text{CO}_2\text{H}.\text{CH}(\text{OH}).\text{CH}(\text{OH}).\text{CO}_2\text{H}$. *Dextro-tartaric acid*. *Di-oxy-succinic acid*. [185°]. S.G. 1.764 (Schiff, A. 113, 189); 1.74 (Buignet, J. 1861, 15); 1.7594 (Perkin). S. 115 at 0°; 132 at 15°; 343 at 100° (Leidie, Fr. 22, 269; O. R. 95, 87; cf. Schiff, J. 1859, 41; Maisch, J. 1865, 892). S. (alcohol) 25.6 at 15°. S. (ether) 4 at 15° (Bourgoin, Bl. [2] 29, 244; A. Ch. [5] 13, 400). $[\alpha]_D = 15.06 - 131p$ in a p per cent. solution (Landolt, B. 6, 1075; Lippmann, B. 24, 3300). H.F. 372,000 (Von Rechenberg). Heat of solution: -3454 at 9° (Pickering, O. J. 51, 376).

Occurs free or as K or Ca salt in grape-juice, tamarinds, unripe mountain-ash berries, madder-root, potatoes, Jerusalem artichokes, sorrel, gherkins, mulberries, pine-apples, black pepper, the leaves of *Chelidonium majus*, the bulbs of *Scilla maritima*, in beet-juice, and in many other plants.

Formation.—1. Mostly together with racemic acid, by oxidation of saccharic acid, dextrose, cane-sugar, milk-sugar, starch, gum arabic, and sorbin by nitric acid (Dessaignes, A. Suppl. 2, 242; Hornemann, J. 1863, 331; Kiliani, A. 205, 175).—2. By the action of sodium-amalgam on

an alcoholic solution of oxalic ether (Debus, A. 166, 124; O. J. 24, 376). The product is probably inactive tartaric acid.

Preparation.—Powdered chalk is added to a boiling solution of cream of tartar; the filtrate is ppd. by calcium chloride, and both ppas decomposed by the proper quantity of boiling dilute H_2SO_4 . The filtrate from CaSO_4 is evaporated to crystallisation. It may be purified by saturating with CaCO_3 , digesting with ZnCl_2 , and decomposing the zinc salt by H_2S (Ficinus, Ar. Ph. [8] 14, 310).

Properties.—Monoclinic prisms, with hemihedral facets; $a:b:c = .785:1: .805$; $\beta = 79^\circ 48'$. Dextrorotatory, the rotation being dependent on the concentration of the solution, and being also greatly affected by the presence of alcohols, acids, and other substances in the solution (Landolt, B. 13, 2329; Biot, J. 1850, 169; Pribram, M. 9, 485; B. 22, 6; Long, Am. S. 86, 351; Thomsen, J. pr. [2] 35, 145). Sodium molybdate in the proportion of Na_2MoO_4 to $2\text{C}_4\text{H}_4\text{O}_6$ increases the rotation 37 times, while ammonium molybdate (1 mol.) increases the rotation of tartaric acid (3 mols.) 56 times (Gernez, C. R. 104, 783; 105, 803). Lithium and magnesium molybdate also increase the rotation. Sodium tungstate also increases the rotation, the maximum effect being 22 times (Gernez, C. R. 106, 1527; 108, 942). Crystals of tartaric acid are strongly pyro-electric. An aqueous solution of tartaric acid is ppd. by baryta, lime, and lead acetate. Potassium salts, when the solution is not too dilute, form a crystalline pp. of $\text{KOC}_4\text{H}_4\text{O}_6$; the formation of the pp. being promoted by rubbing the sides of the vessel with a glass rod and by the addition of alcohol. CaCl_2 ppds. CaA' , from neutral solutions of tartrates; the ppn. is hindered by ammonium salts. Calcium tartrate dissolves in KOHAq and is re-ppd. in gelatinous form on boiling. Reduces ammoniacal AgNO_3 , forming a mirror; the solution then contains oxalic acid (Claus, B. 8, 950). Tartaric acid prevents the ppn. by alkalis of the oxides of Al, Bi, Ni, Co, Cr, Cu, Fe, Pb, Pt, and Zn, even on boiling (Aubel a. Ramdohr, A. 103, 33; Grothe, J. pr. 92, 175). 1 mol. acid prevents the ppn. of 1 mol. $\text{Cu}(\text{OH})_2$. A solution of tartaric acid, coloured by a drop of K_2CrO_7 , gradually becomes colourless (difference from citric acid) (Salzer, B. 21, 1910). A saturated solution of potassium bichromate is slowly turned coffee-brown by tartaric (but not by citric) acid (Cailletet, C. C. 1879, 14). Boiling alkaline KMnO_4 is turned green, and finally brown, by tartaric acid, but only green by citric acid. Decolourises KMnO_4 in acid solution. When H_2SO_4 is present, twice as much KMnO_4 must be added to produce a permanent red colour as when it is absent, for in the latter case $\text{Mn}_2\text{C}_4\text{H}_4\text{O}_6$ is formed (Fleischer, B. 5, 350). Tartaric acid gives an odour of burnt sugar when heated till carbonised. A crystal added to conc. H_2SO_4 , containing 1 p.c. resorcin gives a red colour on warming (difference from citric and maleic acids) (Mohler, Bl. [3] 4, 728).

To detect small quantities of tartaric acid in presence of citric acid. Add about 1 g. citric acid to a 20 p.c. solution of molybdate of ammonia (1 c.c.), then two or three drops of a dilute solution of H_2O_2 , and heat for three minutes on the water-bath. If the citric acid is pure the

solution remains yellow. If 0.1 p.c. or more of tartaric acid is present, the liquid become blue (Crismer, *Bl.* [3] 6, 23).

Reactions.—1. Melts at 135°, changing to the isomeric metatartaric acid. The metatartaric acid may be reconverted into tartaric acid by boiling with water (Grosjean, *C. J.* 43, 334).—2. At 140°–150° water is eliminated and ditartronic acid $C_6H_{10}O_{11}$ is formed. On further heating soluble tartaric anhydride (tartrelic acid), and then insoluble tartaric anhydride, are formed. On further heating the products of distillation (from 250 g.) are pyruvic acid (9 g.), pyrotartaric acid (2 g.), formic acid (4 g.), resins, aldehydes and volatile acids (2 g.), and tarry bodies (3 g.) (P. Liebermann, *B.* 15, 428).—3. Dipyrrotracetone $C_6H_{12}O_2$ (230°), a colourless liquid, with aromatic odour, is among the products of the distillation of tartaric acid. It combines with bromine (Bourgoin, *C. R.* 86, 674).—8. By heating tartaric acid (10 pts.) with water (1 pt.) at 175° it is converted into racemic acid and inactive tartaric acid. At 165° there is a greater yield of the inactive acid (Jungfleisch, *J.* 1872, 615). Heated with more water at 150° it yields CO_2 and pyrotartaric acid (Wedard, *C. C.* 1888, 889).—4. *Potash-fusion* yields acetic and oxalic acids.—5. *Oxidation* by CrO_3 , $KMnO_4$, PbO_2 or MnO_2 , and H_2SO_4 yields CO_2 and formic acid. The rate of oxidation has been studied by Krutwig (*Z. P. C.* 2, 787). By slow oxidation by HNO_3 tartaric acid may be obtained.—6. Reduced by HI and P to malic and succinic acids.—7. PCl_5 forms chloro-fumaric chloride.—8. $FeSO_4$ at 100° yields iso-arabic acid $C_6H_{10}O_8$, a thick dextrorotatory syrup, $[\alpha]_D^{20} = 20^\circ$, yielding the salts CaA' , 9aq, Ca_2OA' , 8aq, PbA' , and $Pb_2A'_2O_2$ (Ballo, *B.* 22, 750).—9. *Chloral* forms $C_6H_7ClO_6$ (124°), crystallising from chloroform in small needles, insol. water, sol. warm alcohol and ether (Wallach, *A.* 193, 46).—10. On submitting tartaric acid to *electrolysis* and treating the syrupy mass with phenyl-hydrazine, glyoxal-osazone [160°] and glyoxal-carboxylic osazone [218°] are obtained (Friedel, *A. Combes*, *Bl.* [3] 8, 770).—11. On adding powdered tartaric acid to fused glucose tartaric glucoside is obtained (Guyard, *Bl.* [2] 41, 291; *cf.* Berthelot, *A. Ch.* [3] 54, 78).—12. *m-Amido-benzoic acid* at 160° forms 'tartrylo-dibenzamic' acid $C_{18}H_{16}N_2O_8$, i.e. $(CO_2H.O_2H.NH.CO)_2C_2H_4(OH)_2$, a colourless powder, insol. water, sol. hot alcohol. Its alkaline salts form yellow solutions in which $Cu(OAc)$ ppts. $C_{18}H_{14}(CuOH)_2N_2O_8$. On heating to 190° it yields the anhydride $C_{18}H_{14}N_2O_6$, a greenish-yellow powder, converted by an alcoholic solution of aniline into tartranil dibenzamic acid

[200°] (Schiff, *A.* 282, 156; *G.* 16, 28). Another product of the action of tartaric acid on *m*-amido-benzoic acid is 'tartryl-benzamic' acid

which crystallises from water in pale-yellow aggregates, yields an acetyl derivative and an anhydride 'tartranbenzamic' acid $C_{11}H_8NO_6$, crystallising from water in green plates, forming $C_{11}H_7BaNO_6$ and $C_{11}H_7CuNO_6$, and converted at 210° in 'benzamtartaric' acid by dehydration. A warm alcoholic solution of aniline converts 'tartranbenzamic' acid into 'tartranilbenzamic'

acid [245°], which yields an acetyl derivative [198°]. 'Tartryl-benzamic' acid heated with dry amido-benzamide at 140° forms the compound $C_{12}H_8(OH)_2(CO.NH.C_6H_4.CONH_2)_2$, a white powder, insol. water, sl. sol. alcohol, and yielding $C_{12}H_{14}CuN_2O_7$ aq.—13. *Glycerin* at 100° yields the compounds $C_8H_8(OH)_2.O.C_2H_5O_2$ and $C_8H_8(OH)(OC_2H_5O)_2$ (Desplats, *J.* 1859, 500). Glycerin at 140° gives $C_{11}H_{11}O_{12}$ and $C_8H_8O_{12}$.—14. *Erythrite* at 100° forms $C_{12}H_{18}O_{11}$, which gives $Ca_3(C_{12}H_{18}O_{11})_2$ 3aq (Berthelot, *A. Ch.* [3] 54, 84).—15. *Quercite* at 120° forms $C_{22}H_{32}O_7$, which gives $Ca_3C_{22}H_{32}O_7$ 2aq.—16. *Pinite* at 120° forms $C_{30}H_{36}O_{15}$, which gives $Ca_3C_{30}H_{36}O_{15}$.—17. *Mannite* at 120° forms $C_{30}H_{40}O_{15}$, which yields $Mg_2O(C_{30}H_{40}O_{15})_2$ 30aq and $Ca_3C_{30}H_{40}O_{15}$ 6aq.—18. *Dulcitol* forms $C_{12}H_{20}O_{11}$, which gives $Ca(C_{12}H_{20}O_{11})_2$ 4aq.—19. *Phenyl hydrazine* (2 mols.) at 140° forms $C_{10}H_{18}N_4O_4$, i.e. $C_2H_4O_2(CO.N_2H_2Ph)_2$ [226°] (Bülow, *A.* 236, 196); [c. 240°] (Fischer, *A.* Passmore, *B.* 22, 2734), crystallising from alcohol in plates.

Estimation.—Methods for estimating tartaric acid have been described by Scheurer-Kestner, *C. R.* 86, 1024; Berthelot, *Fr.* 3, 216; Vogel a. Braun, *Fr.* 7, 149; Kissel, *Fr.* 8, 409; Fleischer, *Fr.* 12, 328; Oliveri, *G.* 14, 453; Piccard, *Fr.* 21, 424; C. Schmitt a. Hiepe, *Fr.* 21, 539; Anthor, *Fr.* 21, 195; Nessler a. Barth, *Fr.* 21, 60; 22, 159; Kayser, *Fr.* 22, 123; 23, 29; Musset, *Fr.* 24, 279; Ferrari, *Fr.* 24, 279; Warrington, *C. J.* 28, 25; Grosjean, *C. J.* 35, 841; Klein, *Fr.* 24, 379; Bronträger, *Fr.* 25, 327; 26, 699; Gantter, *Fr.* 26, 714; Von Lorenz, *Fr.* 27, 8; Philips, *Fr.* 29, 577; Goldenberg, *Fr.* 22, 270; Heidenhain, *Fr.* 27, 681; Weigert, *Fr.* 23, 357; Haas, *C. C.* 1888, 1045; Ward, *Ph.* [3] 19, 880.

Salts (Berzelius, *P.* 19, 305; 36, 4; *A. Ch.* [2] 67, 303; Werther, *J.* pr. 22, 383; Dumas a. Piria, *A. Ch.* [3] 5, 353; De la Provostaye, *A. Ch.* [3] 8, 129).— $(NH_4)_2A''$. $[\alpha]_D = 33.7^\circ$ in a 1.2 p.c. solution (Sonnenthal, *M.* 12, 603). Efflorescent monoclinic prisms, v. sol. water; $a:b:c = .868:1.1:244$ $\alpha = 88^\circ 9'$. Give off NH_3 in air. Yield succinic acid on fermentation (Koenig, *G.* 11, 180).— $(NH_4)HA''$. $[\alpha]_D = 25.7^\circ$ (Landolt). Minute laminae, sl. sol. cold water. Forms with ammonium malate $(NH_4)HA''(NH_4)C_4H_4O_6$, crystallising in prisms, *S.* 9 (Pasteur, *J.* 1853, 415).— K_2A'' ½ aq. $[\alpha]_D = 25.5^\circ$ in a 2 p.c. solution. *S.* 133 at 2°; 158 at 28° (Osann). V. sl. sol. hot alcohol. Monoclinic crystals; $a:b:c = .402:1.1:109$; $\alpha = 75^\circ 12'$.— KHA'' . *Cream of tartar*. $[\alpha]_D = 22^\circ$ in a .4 p.c. solution. 100 g. solution contain .369 + .000569 g. grammes at t° (Blarez, *C. R.* 112, 434, 808). *S.* .25 at 0°; .4 at 10°; .55 at 20°; 1.18 at 40° (Chancel, *C. R.* 60, 408; *cf.* Alluard, *C. R.* 59, 500). Obtained by crystallisation of argol, which is deposited during vinous fermentation. Trimetric crystals; $a:b:c = .712:1:737$. Insol. alcohol.— Na_2A'' 2aq. $[\alpha]_D = 81^\circ$ in a 1 p.c. solution (Sonnenthal; *cf.* Thomsen, *J. pr.* [2] 34, 80; 35, 145). *S.* 29 at 6°; 44 at 24°; 66 at 42.5° (Osann). Trimetric prisms; $a:b:c = .770:1.1:337$. V. sol. hot water, insol. alcohol.— $NaHA''$. $[\alpha]_D = 24.8^\circ$ in a 1.3 p.c. solution (*S.*).— $NaHA''$ aq (Dumas a. Piria, *A.* 44, 80). *S.* 11 in the cold; 55 at 100°. Minute crystals, with hemihedral facets. Insol. alcohol.— Li_2A'' . $[\alpha]_D = 37.5^\circ$ in a .7 p.c. solution (*S.*). Deliques-

cent.—LiHA'' 1½aq. Small crystals, v. sol. water (Dulk, *Schw.* J. 64, 180, 193; A. 2, 47).—LiHA''aq.—Li₂H₂A''TeO 2aq. Needles (Klein, A. Ch. [6] 10, 118; C. J. 51, 351). Large trimetric prisms, with hemihedral facets. Melts at 70°–80° in its water of crystallisation, and becomes anhydrous at 215° (Fresenius, A. 53, 234). [*a*]_D = 29.7° (L.). *Molecular rotation*: Long, *Am. S.* 36, 351.—K₂A''TeO (dried at 100°).—RbHA''. Trimetric prisms, isomorphous with the caesium salt; *a:b:c* = 726:1:695 (J. P. Cooke, *Am. S.* [2] 37, 70). S. 1.18 at 25°; 11.7 at 100° (Allen, *Am. S.* [2] 34, 367).—NaRbA'' 4aq. Isomorphous with Rochelle salt (Piccard, J. 1862, 125).—Cs₂A''. Trimetric prisms. S. 10 at 25°; 100 at 100°.—TLiA''½aq. [*a*] = 4.8° in a 5 p.c. solution at 20°. Sl. sol. water and alcohol.—TlHA''. [*a*] = 12° in a 1 p.c. solution at 20°. Small flat prisms (De la Provostaye, A. Ch. [3] 3, 129; Kuhlmann, J. 1862, 188).—TlNaA'' 4aq. At 20° [*a*] = 0° in a 5 p.c. solution and 6.5° in a 20 p.c. solution.—TlLiA''aq. [*a*] = 9.5° in a 5 p.c. solution at 20°.—TlKA''. [*a*] = 10° in a 5 p.c. solution at 20°.—Tl(NH₄)A''. [*a*] = 10° in a 5 p.c. solution at 20°.—BaA''. White amorphous pp., becoming crystalline. S.G. $\frac{214}{4}$ 2.973 (Clarke, *Am. S.* 2, 174).—BaA''aq (Dulk). S. (amorphous) 1.2; (crystalline) .077 (Vogel a. Reischauer, J. 1859, 288). K₂BaA'' 2aq. Powder, sl. sol. water.—Na₂BaA'' 2aq. Needles, sl. sol. water, more soluble in a solution of Rochelle salt. Ppd. on mixing a solution of Rochelle salt with BaCl₂.—BaA''TeO (dried at 100°).—SrA'' 4aq. Monoclinic prisms. S. 7 at 16°. S.G. $\frac{198}{4}$ 1.966 (Clarke).—SrA'' 3aq (Marignac, *Ann. M.* [5] 15, 280).—(NH₄)₂SrA'' 12aq. Thin plates.—K₂SrA'' 2aq.—Na₂SrA'' 2aq.—CaH₂A''. S. 71 at 15.6°. Trimetric crystals.—CaA'' 4aq. Occurs in grapes. Ppd. as white crystalline powder on adding CaCl₂ to a solution of K₂A''. Small trimetric prisms. *a:b:c* = 872:1:908 (Anschütz, A. 226, 191). S. .016 at 15°; .3 at 100° (Mohr, J. 1865, 393). Forms, with calcium malate, the double salt CaA''CaH₂O₆ 6aq, crystallising in needles, S. 1.25 at 17° (Ordonneau, *Bl.* [3] 6, 262).—MgA'' 4aq. S. .8 at 16°. [*a*]_D = 36°.—Mg₂C₂H₂O₆ 3aq. S. .024. Ppd. by adding NH₃ to a solution of MgA'' (Mayer, A. 101, 166).—MgNa₂A'' 10aq.—MgK₂A'' 8aq.—MgH₂A''. S. 2 at 16°.—BaA'' 3aq (Atterberg, *Bl.* [2] 21, 162).—BeK₂C₂H₂O₆ 3aq. Prisms (Toczynski, Z. 1871, 277).—K(SbO)A''½aq. *Tartar emetic*. Prepared by boiling Sb₂O₃ (3 pts.) with cream of tartar (4 pts.) and water. Octahedra; *a:b:c* = 956:1:1.054. [*a*] = 141° in a 4 p.c. solution at 20°. S.G. 2.6. Efflorescent. At 200° it becomes K(SbO)C₂H₂O₆. S. 5 at 8°; 8 at 21°; 52

at 100°. .05 to .1g. produce vomiting. Its solution reddens litmus, and gives a crystalline pp. of K(SbO)A'' with alcohol. Its solution is ppd. by mineral acids, by alkalis, and by H₂S. HgCl₂ is reduced by it to calomel. Heat of formation: Guntz, C. R. 104, 699. Volumetric estimation of Sb in tartar emetic (Dunstan a. Boole, *Ph.* [3] 19, 385).—K(SbO)A''H₂A'' 2½aq. Efflorescent prisms. Alcohol added to its aqueous solution ppts. tartar-emic, leaving tartaric acid in solution (Knapp, A. 32, 76).—K(SbO)A''3KHA''. Mammellated groups of needles, v. sol. water.—(K(SbO)A'')₂NaNO₃ (Martenson, J. 1869, 539).—Na(SbO)A''½aq. Trimetric, hygroscopic prisms; *a:b:c* = 922:1:1.08. —(NaA'')₂Sb(OH)₃ 8aq. Amorphous, v. sol. water (Clarke a. Evans, B. 16, 2385).—NH₄(SbO)A''½aq.—NH₄(SbO)A''2½aq (Berlin, A. 64, 359).—Rb(SbO)A''½aq. Isomorphous with tartar-emic (Grandeau, A. Ch. [3] 67, 155).—Tl(SbO)C₂H₂O₆ aq. [*a*] = 100° in a 2 p.c. solution at 20° (Long, *Am. S.* [3] 38, 264).—Ag(SbO)A''½aq. Crystals (J. P. Cooke, *Am. S.* [3] 19, 393).—Ba(SbO)A''½aq.—Cd(SbO)A''2½aq. Converted at 200° into Cd(SbOC₂H₂O₆)₂ (Schiff, A. 104, 328).—(Ca(SbO)A'')₂Ca(NO₃)₂ 24aq. Crystallises from a solution of tartar-emic mixed with calcium nitrate in trimetric forms (Marignac, *Ann. M.* [5] 15, 280).—Sr(SbO)A''½aq. Hexagonal crystals.—Sr₂(SbO)A''(NO₃)₂ 12aq. Very soluble crystals (Kessler, P. 75, 410).—Pb(SbO)A''½aq. —Be₂Sb₂(C₂H₂O₆)₂—Sb(HA'')₂ 4aq. Needles, v. sol. water (C. a. E.).—Sb₂A'' 6aq.—(SbO)HA''aq (Clarke a. Stallo, B. 13, 1788).—(SbO)HA'' (Guntz, C. R. 104, 850).—C₂H₂O₆Sb₂O₆ aq. White granular pp., formed by adding alcohol to a solution of Sb₂O₃ in aqueous tartaric acid (Berzelius). Converted by heat into SbOC₂H₂O₆—(C₂H₂O₆)₂Sb₂O₆ 6aq (Péligot, A. Ch. [3] 20, 289).—(C₂H₂O₆)₂Sb₂O₆ (dried) (P.).—(C₂H₂O₆)₂Sb₂O₆H₂O. Crystals (Guntz, A. Ch. [6] 13, 396).—Berberine salt C₂₀H₁₁NO₄(SbO)A'' (Stenhouse, J. 1863, 452).—Brucine salt C₂₀H₁₁N₂O(SbO)A''.—Quinine salt C₂₀H₂₁N₂O₂(SbO)A'' (Clarke, B. 15, 1540).—Atropine salt C₁₇H₁₉NO₃(SbO)A'' 2aq.—Aniline salt C₈H₉N(SbO)A''. Long white prisms. S.G. 1.89 at 11°.—NH₄(AsO)A''½aq. Large efflorescent trimetric crystals; *a:b:c* = 876:1:694. Got by dissolving As₂O₃ in NH₄HA'' (Mitscherlich; Werther, J. pr. 32, 409).—K(AsO)A'' 2½aq. Got by dissolving arsenic acid in a solution of cream of tartar (Pelouze, A. Ch. [3] 6, 63).—(Sr(AsO)A'')₂NH₄NO₃ 12aq. Large trimetric crystals (Marignac).—Bi₂A'' 6aq. Small crystals, decomposed by water (Schneider, P. 88, 55).—K(BiO)C₂H₂O₆ (Schwarzenberg, A. 61, 244).—Bi₂K(BiO)C₂H₂O₆ (Frisch, J. 1866, 401).—K(BO)A'' (dried at 100°). *Potassium borotartarate*. Amorphous mass, v. sol. water, insol. alcohol. At 100° it becomes K(BO)C₂H₂O₆. Purgative. [*a*] = 58° in a 20 p.c. solution at 20°.—K₂(BO)C₂H₂O₆—K₂(BO)C₂H₂O₆—Na(BO)A''.—Na₂(BO)C₂H₂O₆—Na₂(BO)C₂H₂O₆ (Duve, J. 1869, 540).—K₂(BO)C₂H₂O₆Na(BO)A''.—Ba(BO)C₂H₂O₆—Ba(BO)C₂H₂O₆—PbA''. S.G. $\frac{172}{4}$ 4.012 (Clarke, *Am. S.* 2, 174). White crystalline pp., v. sol. HNO₃.—Pb₂C₂H₂O₆ aq (Erdmann, A. 21, 14). Insol. water, v. sol. KOHAq.—Pb₂(C₂H₂O₆)₂—Ce₂A'' 9aq (?).—Th₂KA''.—CuA'' 3aq. S. .06 in the cold; .3 at 100°. Light-

green powder.— $\text{CuA}''4\text{NH}_3$ (Schiff, *A.* 123, 46).— $(\text{H}(\text{NH}_4)\text{A}')_2(\text{HgO})_3\text{H}_2\text{O}$ (Harff, *Brandes' Arch.* 5, 259; Burokhardt, *ibid.* [2] 11, 257).— $(\text{KHA}')_2\text{HgCl}_2 \cdot 6\text{aq.}$ — $\text{K}_2\text{NIA}''_2$ (dried at 110°). Efflorescent, apple-green crystalline powder (Fabian, *A.* 103, 248).— $\text{CoCl}(\text{HA}')_2 \cdot 5\text{NH}_3 \cdot 2\frac{1}{2}\text{aq}$ (Jørgensen, *J. pr.* [2] 18, 239).— $\text{ZnA}''2\text{aq}$ (Schiff, *A.* 125, 146).— $\text{Zn}_3\text{C}_2\text{H}_2\text{O}_8 \cdot \frac{1}{2}\text{aq.}$ Powder, insol. water.— $\text{Cr}(\text{OH})\text{A}''$. Violet flakes, turning dark-blue over H_2SO_4 (Schiff, *A.* 125, 145). At 220° it yields $\text{CrO}_3 \cdot \text{H}_2\text{O}$.— $\text{K}(\text{CrO})\text{A}''3\frac{1}{2}\text{aq}$ (Malaguti, *C. R.* 16, 457).— $(\text{UO}_2)\text{A}''3\text{aq}$ (Péligot, *A.* 56, 231).— $\text{K}_2(\text{UO}_2)\text{A}''_2$ (dried at 200°).— $(\text{SbO})_2(\text{UO}_2)\text{A}''_2 \cdot 8\text{aq.}$ — SnA'' . Minute crystals.— $\text{K}(\text{FeO})\text{A}''4$ or 5aq. Prepared by digesting cream of tartar with water and $\text{Fe}(\text{OH})_3$. Brown scales, red by transmitted light. Acids ppt. from its solutions a basic salt, sol. excess.— $\text{NH}_4(\text{FeO})\text{A}''4$ (or 5) aq.— $\text{Fe}_2\text{A}''_3$.— FeA'' . Formed by boiling tartaric acid with water and iron wire (Méhu, *N. J. P.* 40, 257). Minute crystalline powder. *S.* $\cdot 877$ at 15.6° (Dulk, *A.* 2, 62).— $\text{K}(\text{MnO})\text{A}''4\text{aq}$ (Descamps, *J.* 1870, 317).— $\text{Ag}_2\text{A}''$. Amorphous curdy pp. got by adding AgNO_3 to a cold solution of Rochelle salt. Crystallises from a warm solution in white scales. Nearly insol. water. Its ammoniacal solution deposits Ag on warming (Liebig a. Redtenbacher, *A.* 38, 132; Erdmann, *J. pr.* 25, 504).— AgHA'' (Perkin, *C. J.* 51, 869). Monoclinic tables.

Ethylene-diamine salt

$\text{C}_2\text{H}_4\text{O}(\text{N}_2\text{H}_4\text{C}_2\text{H}_4)_2$. Dextrorotatory. Leaflets, v. sol. water. The acid salt is sl. sol. water, *S.* 8 at 15° , and the solution is dextrorotatory (Colson, *Bl.* [3] 7, 808).

Mono-methylether MeHA''. Formed by boiling tartaric acid with MeOH (Guérin, *A.* 22, 248). Prisms.— KMeA'' .— $\text{BaMe}_2\text{A}''_2$ aq (Dumas a. Péligot, *A. Ch.* [2] 61, 200; [3] 5, 373).

Di-methyl ether Me_2A''. [48°]. (280° i.v.). *S.G.* (liquid) $\frac{12}{13.40}$. [α_D] = 2.454 at 18° (Anschütz a. Pictet, *B.* 13, 1176; 18, 1399); = 2.14 (Phillips a. Guye, *C. R.* 110, 714). Yields an acetyl derivative [103°] [α_D] = -14° and a dibenzoyl derivative [α_D] = -88.6° .

Mono-ethyl ether EtHA''. [90°]. Formed by dissolving tartaric acid in boiling alcohol (G.; Marian, *N. J. T.* 13, 2, 43; Trommsdorff, *N. J. T.* 24, 1, 11; Guérin, *A. Ch.* [2] 62, 57). Very deliquescent prisms.— NaEtA'' . Powder, sl. sol. alcohol (Mulder, *B.* 8, 370).— KEtA'' . *S.* 106° at 29.5° . Colourless trimetric prisms; *abc*:*c* = $288:1:417$.— $\text{Ca}(\text{EtA}')_2 \cdot 5\text{aq.}$ — $\text{Ba}(\text{EtA}')_2 \cdot 2\text{aq.}$ *S.* 38 at 23° ; 128 at 100° .— $\text{Pb}(\text{EtA}')_2$.— $\text{Cu}(\text{EtA}')_2 \cdot 6\text{aq.}$ Blue silky efflorescent needles.— AgHA'' . Prisms.

Di-ethyl ether Et_2A''. (280° i.v.). (233° cor. at 197mm.). *S.G.* $\frac{12}{13}$ 1.2097 ; $\frac{22}{23}$ 1.2019 . [α_D] = 9 at 18° (Anschütz a. Pictet, *B.* 13, 1176); 7.22 at 12° ; 8.02 at 20° (Perkin, *C. J.* 51, 863). *M.M.* 8.766 at 14.8° . Liquid miscible with water (Demondésir, *A.* 80, 301). Sodium forms $\text{CO}_2\text{Et} \cdot \text{CH}(\text{ONa}) \cdot \text{CH}(\text{OH}) \cdot \text{CO}_2\text{Et}$ and $\text{CO}_2\text{Et} \cdot \text{CH}(\text{ONa}) \cdot \text{CO}_2\text{Et}$, the latter being converted by EtCl into a deposit and a liquid, part of which is soluble in alcohol and ether and part insoluble in alcohol and ether (Mulder, *R. T. C.* 8, 375; 9, 238; 10, 171; cf. Cohn, *B.* 20, 2003). The soluble product mixed with alcoholic CuCl_2 and poured into water forms

a pp. crystallising in light-green needles, sol. alcohol and ether, insol. water and $\text{CuCl}_2 \cdot \text{H}_2\text{O}$. Tartaric ether is converted by treatment with gaseous HCyO into allophanyl-tartaric ether $\text{NH}_2 \cdot \text{CO} \cdot \text{NH} \cdot \text{CO} \cdot \text{O}(\text{C}_2\text{H}_4\text{Et})_2$ [188°], which is m. sol. hot water and alcohol.

Acetyl derivative of the ether $\text{CO}_2\text{Et} \cdot \text{CH}(\text{OAc}) \cdot \text{CH}(\text{OH}) \cdot \text{CO}_2\text{Et}$. Formed from the ether and AcCl , the mixture becoming hot (Perkin, *C. J.* 20, 145). Heavy oil, sl. sol. water, insol. saline solutions. Neutral to litmus.

Di-acetyl derivative of the ether $\text{CO}_2\text{Et} \cdot \text{CH}(\text{OAc}) \cdot \text{CH}(\text{OAc}) \cdot \text{CO}_2\text{Et}$. [67°]. (292°) (Pictet, *B.* 14, 2790); (230° at 100mm.). Formed by heating tartaric ether with AcCl at 100° (Perkin; Wislicenus, *A.* 129, 187). Prisms (from water), v. sl. sol. water. Slowly saponified by KOH aq.

Acetyl-benzoyl derivative of the ether $\text{CO}_2\text{Et} \cdot \text{CH}(\text{OAc}) \cdot \text{CH}(\text{OBz}) \cdot \text{CO}_2\text{Et}$. Formed by heating the mono-benzoyl derivative of the ether with AcCl at 150° (Perkin). Heavy oil.

Mono-benzoyl derivative of the ether $\text{CO}_2\text{Et} \cdot \text{CH}(\text{OH}) \cdot \text{CH}(\text{OBz}) \cdot \text{CO}_2\text{Et}$. [64°]. Formed by heating the ether with BzCl at 100° . Prisms, sl. sol. hot aq. Saponified by alcoholic potash yielding $\text{C}_2\text{H}_5(\text{OH})(\text{OBz})(\text{CO}_2\text{Et}) \cdot \text{CO}_2\text{K}$, $\text{C}_2\text{H}_5(\text{OH})(\text{OBz})(\text{CO}_2\text{K})$, and finally, potassium tartrate. $\text{C}_2\text{H}_5(\text{OH})(\text{OBz})(\text{CO}_2\text{Et}) \cdot \text{CO}_2\text{H}$ forms tufts of needles, sl. sol. water.

Di-benzoyl derivative of the ether [α_D] = -60° (Phillips a. Guye, *C. R.* 110, 716).

Di-n-propyl ether Pr_2A''. (303° i.v.). *S.G.* $\frac{12}{13.92}$. [α_D] = 13.77 at 18° (A. a. P.); = 12.44 (P. a. G.).

Di-isopropyl ether Pr_2A''. (275°). *S.G.* $\frac{22}{1.130}$. [α_D] = 14.89 at 20° (Pictet, *J.* 1882, 856). Liquid.

Di-isobutyl ether (Pr.CH_3)_2A''. [68°]. (324°). *S.G.* $\frac{122}{1.015}$. [α_D] = 19.9° (P.). Yields a dibenzoyl derivative [α_D] = -42° .

Isoamyl ether (C_4H_9)_2A''. Formed by digesting tartaric acid (150 pts.) with isoamyl alcohol (88 pts.) at 130° (Balard, *A. Ch.* [3] 12, 309; Breunlin, *A.* 91, 814). Nodular mass, with very bitter taste.— $\text{KC}_2\text{H}_{11}\text{A}''$ aq. Crystalline.— $\text{NaC}_4\text{H}_9\text{A}''$. Nodules.— $\text{Ba}(\text{C}_4\text{H}_9\text{A}')_2 \cdot 2\text{aq.}$ pearly plates (from water).— $\text{Pb}(\text{C}_4\text{H}_9\text{A}')_2$.— $\text{Ca}(\text{C}_4\text{H}_9\text{A}')_2$.— $\text{AgC}_4\text{H}_9\text{A}''$. Tufts of needles.

Di-acetyl derivative $\text{C}_6\text{H}_5\text{O} \cdot \text{i.e.}$ $\text{CO}_2\text{H} \cdot \text{CH}(\text{OAc}) \cdot \text{CH}(\text{OAc}) \cdot \text{CO}_2\text{H}$. [α_D] = -23.14 (Phillips a. Guye, *C. R.* 110, 716). Formed slowly from the anhydride by the action of water. Hard deliquescent crystals (containing 3aq), melting at 58° . V. sol. water, alcohol, and ether, sl. sol. benzene. Lævorotatory. Its salts form lævorotatory solutions (Colson, *Bl.* [3] 7, 806; *C. R.* 114, 417). Converted into tartaric acid by hot KOH aq. — KHA'' : crystalline powder.— BaA'' : slender deliquescent needles.— CaA'' .— CuA'' .— AgA'' : white crystalline mass.—Ethylene-diamine salt $\text{C}_6\text{H}_5\text{O}(\text{N}_2\text{H}_4\text{C}_2\text{H}_4)_2$. Lævorotatory. V. sol. water.

Anhydride of the di-acetyl derivative $\text{C}_6\text{H}_5\text{O} \cdot$ [127°]. Formed by heating tartaric acid with AcCl (Ballik, *Sitz.* W. 29, 26; Pilz, *Sitz. W.* 44 [2] 7; Perkin, *C. J.* 20, 149). Slender needles (from benzene). Dextrorotatory.

Benzoyl derivative $\text{C}_6\text{H}_5\text{O} \cdot \text{i.e.}$ $\text{CO}_2\text{H} \cdot \text{CH}(\text{OH}) \cdot \text{CH}(\text{OBz}) \cdot \text{CO}_2\text{H}$. Formed by heating tartaric acid with benzoic acid at 150°

(Dessaigues, *J. Ph.* [3] 82, 47). Minute crystals, v. sol. water, sl. sol. alcohol.— $\text{Ag}_2\text{A}'$: white pp.

Di-benzoyl derivative $\text{C}_{18}\text{H}_{14}\text{O}_6$, i.e. $\text{CO}_2\text{H}.\text{CH}(\text{OBz}).\text{CH}(\text{OBz}).\text{CO}_2\text{H}$. [90°].

$[\alpha]_D = -116^\circ$ in alcohol. Formed by dissolving its anhydride in hot water. Needles (containing aq.). Converted by heat into a crystalline substance melting at 132° .

Anhydride $\text{C}_4\text{H}_2\text{O}_5$. [174°]. $[\alpha]_D = 143^\circ$ in acetone at 18° . Formed by heating tartaric acid with BzCl . Small needles, insol. cold water, sol. alcohol, benzene, and alkalis. Dextro-rotatory.

Di-nitroxy- derivative

$\text{CO}_2\text{H}.\text{CH}(\text{NO}_2).\text{CH}(\text{NO}_2).\text{CO}_2\text{H}$. *Nitrotartaric acid*. Formed by dissolving tartaric acid (1 pt.) in HNO_3 (4½ pts.), and stirring with an equal volume of H_2SO_4 (Dessaigues, *A.* 82, 362; 89, 339). The crystals are dried and crystallised from ether (Kekulé, *A.* 221, 245). Silky prisms, decomposed by hot water, forming oxalic and tartaric acids, CO_2 , and NO . Alcohol containing HNO_3 forms di-oxy-tartaric acid. Ammonium sulphide reduces it to tartaric acid.— $(\text{NH}_4)\text{HA}'$.— $\text{Ag}_2\text{A}''$ aq. V. sol. water.— $\text{Et}_2\text{A}''$. [46°]. S.G. 1.278. Formed by dissolving tartaric ether in a mixture of HNO_3 and H_2SO_4 and ppg. with water.

Amide $\text{C}_4\text{H}_4\text{O}_4(\text{CO.NH}_2)_2$. Formed by passing NH_3 into an alcoholic solution of the ether, or of its di-acetyl derivative (Demondesir, *A.* 80, 303; Pasteur, *C. R.* 35, 176; Grote, *A.* 130, 202; Ruhemann, *B.* 20, 3366). Trimetric crystals (from water), v. e. sol. water. Dextro-rotatory.

Amic acid $\text{C}_4\text{H}_4\text{NO}_4$, i.e.

$\text{CO}_2\text{H}.\text{CH}(\text{OH}).\text{CH}(\text{OH}).\text{CO.NH}_2$. Formed by passing NH_3 over tartaric anhydride moistened with alcohol (Laurent, *Compt. Chim.* 1846, 153). Formed also, together with tartaric acid, by heating tartaric ether with NH_4Aq at 100° (Grote). Syrup.— CaA_2 6aq; tetrahedra, v. sol. water.— $\text{Pb}_2(\text{C}_4\text{H}_4\text{NO}_4)_2$.— BaA' , 8aq.— EtA' .

Anilide $\text{C}_8\text{H}_6\text{O}_4(\text{CO.NHPh})_2$. [250°]. Formed by boiling aniline with tartaric acid (Polikier, *B.* 24, 2959). Pearly scales, insol. water, sl. sol. other solvents. Yields mono-, di-, and tri-acetyl derivatives, melting at 227° , 216° , and 137° respectively.

Phenyl-amic acid $\text{C}_{10}\text{H}_{11}\text{NO}_4$, i.e.

$\text{CO}_2\text{H}.\text{CH}(\text{OH}).\text{CH}(\text{OH}).\text{CO.NHPh}$. [180°]. Formed by boiling the phenylimide with NH_4Aq (Arppe, *A.* 93, 352). Plates, v. sol. water and alcohol.— BaA'_2 : spangles, m. sol. hot water.— AgA' : white powder, v. sl. sol. water.

Phenylimide $\text{C}_{10}\text{H}_9\text{NO}_4$, i.e.

$\text{CH}(\text{OH}).\text{CO} > \text{NPh}$. [230°]. Formed, together with the anilide, by heating tartaric acid with aniline at 150° . Pearly plates, v. sol. water.

Di-o-toluide $\text{C}_{12}\text{H}_{11}\text{O}_4(\text{CO.NH.C}_6\text{H}_4\text{Me})_2$. [183°]. White plates, insol. water (Bischoff, *B.* 23, 2049). Ac_2O at 140° yields a di-acetyl compound [222°].

Di-p-toluide $\text{C}_{12}\text{H}_{11}\text{O}_4(\text{CO.NH.C}_6\text{H}_4\text{Me})_2$. [264°]. Got by heating *p*-toluidine with tartaric acid at 185° . Silky needles (from alcohol). Converted by Ac_2O into a di-acetyl derivative [202°].

Hydrazide $\text{C}_4\text{H}_4(\text{OH})_2(\text{CO.NH.NH}_2)_2$. [188°]. Formed from tartaric ether and hydra-

zine hydrate (Von Rothenburg, *B.* 26, 2057). Needles, sl. sol. alcohol. Converted by benzoic aldehyde into $\text{C}_6\text{H}_5(\text{OH})_2(\text{CO.N}_2\text{H}:\text{CHPh})_2$ [225°], crystallising in yellowish plates (from alcohol).

Lævo- tartaric acid

$\text{CO}_2\text{H}.\text{CH}(\text{OH}).\text{CH}(\text{OH}).\text{CO}_2\text{H}$. *Anti-tartaric acid*. [170°]. When a solution of racemic acid is divided into two equal parts and one is neutralised by ammonia and the other by soda, and the solutions mixed and allowed to evaporate, hemihedral crystals of $\text{Na}(\text{NH}_4)\text{C}_4\text{H}_4\text{O}_6$ are obtained. Half of these crystals have the hemihedral faces oppositely situated to those of the other half; and on carefully selecting the two kinds of crystals (the solutions of which exhibit equal and opposite action on polarised light), ppg. their solutions by lead nitrate, and decomposing the lead salts by H_2S or H_2SO_4 , solutions are obtained which on evaporation yield crystals, the one of dextro- and the other of lævo- tartaric acid (Pasteur, *A. Ch.* [3] 28, 56). If in a solution of sodium ammonium racemate of S.G. 1.26 a crystal of the dextro- salt be put on one side and one of the lævo- salt be put on the other side of the vessel, the two salts will crystallise separately (Jungfleisch, *J. Ph.* [5] 5, 346). The separation of sodium ammonium racemate into the dextro- and lævo- tartrates does not take place if the solution is heated to 118° in a sealed tube and allowed to crystallise without access of air (Bichat, *Bl.* [2] 46, 54). According to Wyruboff (*C. R.* 102, 627), the splitting up of the sodium ammonium racemate depends upon strength of solution and temperature only.

Lævo-tartaric acid is exactly like dextro tartaric acid in solubility and S.G. Its crystals are like the reflection of those of the dextro-acid. The two acids are oppositely pyro-electric. Solutions of the lævo- acid exhibit an effect on light equal and opposite to that produced by solutions of the dextro- acid of like strength. When conc. solutions of equal quantities of the dextro- and lævo- acids are mixed, heat is given out and racemic acid separates. The salts of the lævo-tartaric acid have the same amount of water of crystallisation, and the same crystalline form as the salts of dextro-tartaric acid. They exhibit opposite hemihedry, opposite rotation, and are oppositely pyro-electric. Differences are observed between the compounds of the two acids with optically active substances. Acid ammonium (active) malate combines with acid ammonium dextro- (but not lævo-) tartrate. Cinchonine lævo- tartrate $\text{C}_{19}\text{H}_{22}\text{N}_2\text{O}_6\text{H}_2\text{O}_6$ contains aq, while the dextro-tartrate contains 4aq.

Di-methyl-ether $\text{Me}_2\text{A}'$. [48°]. (160° at 16 mm.). Lævorotatory (Anschtütz, *B.* 18, 1398; *A.* 247, 112).

Di-acetyl derivative of the di-methyl ether

$\text{CO}_2\text{Me}.\text{CH}(\text{OAc}).\text{CH}(\text{OAc}).\text{CO}_2\text{Me}$. [103°]. $[\alpha]_D = -1.3$ (in a 3.6 p.c. solution in alcohol of S.G. 826). Formed by heating $\text{Me}_2\text{A}'$ with AcCl . Monoclinic plates (from benzene); $a:b:c = 1.052:1.1007$; $\beta = 87^\circ 54'$. On mixing with the corresponding dextro-compound it forms the isomeric racemic compound [86°].

Amide $\text{C}_4\text{H}_4\text{O}_4(\text{NH}_2)_2$. Combines with the amide of active malic acid, forming needles, 5. more than 55.

Racemic acid $C_4H_4O_6$. *Paratartaric acid*. [206°] (Bischoff, *B.* 22, 1812). S.G. (of H_2A'') 1.778; (of H_2A'' aq) 1.687 (Perkin, *C. J.* 51, 866). S. (of H_2A'') 8.16 at 0°; 18 at 20°; 187.8 at 100°. S. (of H_2A'' aq) 9.23 at 0°; 20.6 at 20°; 184.9 at 100° (Liedie, *C. R.* 95, 87). Heat of solution at 9°: -5675 (for H_2A''); -7065 (for H_2A'' aq) (Pickering, *C. J.* 51, 367). H.C. (for H_2A'') 1,851,190 (Ossipoff, *C. R.* 108, 1105). H.F. (for H_2A'' aq) 278,400. Acid potassium racemate either occurs sometimes in crude argol, or is produced therefrom in the purification processes (Kestner; Jungfleisch, *C. R.* 85, 805). On crystallisation of cream of tartar, acid potassium racemate remains in the mother-liquor.

Constitution.—Assuming racemic acid to be a compound of the dextro- and lævo-tartaric acids, its formula must be at least $(C_4H_4O_6)_2$.

Formation.—1. By mixing solutions of dextro- and lævo-tartaric acids.—2. By heating tartaric acid (30 g.) with water (4 c.c.) for 30 hours at 175° (Jungfleisch, *Bl.* [2] 18, 203).—3. By heating the dextro- or lævo-tartrate of quinine or cinchonine at 170° (Pasteur, *A.* 72, 164; 84, 157; 88, 211).—4. By heating tartaric ether.—5. By heating inactive tartaric acid at 200° or by boiling it with HCl aq (Dessaingnes, *Bl.* 1865, i. 34).—6. By oxidation of fumaric acid by aqueous $KMnO_4$ (Kekulé a. Anschütz, *B.* 18, 2150; *A.* 226, 191; cf. Tanatar, *B.* 12, 2293). 7. By the action of HNO_3 on lævulose, mucic acid, and inulin; and, together with tartaric acid, by the action of HNO_3 on milk sugar, cane sugar, saccharic acid, dulcitol, and mannitol (Carlet, *Rép. Chim. pure*, 2, 345; 4, 17; Hornemann, *J. pr.* 89, 283).—8. Together with inactive tartaric acid by boiling silver di-bromo-succinate with water (Perkin a. Duppa, *C. J.* 13, 102; Pasteur, *A. Suppl.* 2, 242; Jungfleisch, *Bl.* [2] 19, 193).—9. By boiling silver iso-di-bromo-succinate with water (Demuth a. Meyer, *B.* 21, 268). 10. By boiling glyoxal with dilute HCl and HCl (Schäyen, *A.* 132, 168; Strecker, *Z.* [2] 4, 216).—11. By the action of zinc-dust (2 mols.) and dilute $HOAc$ (3 mols.) on glyoxylic acid (1 mol.) at 100° (Geniviesse, *Bl.* [3] 7, 225; *C. R.* 114, 555).—12. From piperic acid, sorbic acid, and $CHO.CH:CH.CH:CH.CO_2H$ by careful oxidation with dilute $KMnO_4$ below 4° (Debnar, *B.* 23, 2374).—13. By heating a solution of desoxalic acid (Löwig, *J.* 1861, 605; Klein, *J. pr.* [2] 20, 157).

Preparation.—Sodium ammonium racemate, got from the mother-liquor from which cream of tartar has separated, is treated exactly in the same way as cream of tartar in the preparation of tartaric acid. The small opaque needles of racemic acid can be separated by handpicking from the large transparent crystals of tartaric acid.

Properties.—Triclinic crystals (containing aq); $a:b:c = .484:1:806$; $\alpha = 120^\circ$; $\beta = 96^\circ 13'$; $\gamma = 76^\circ 5'$ (De la Provostaye, *A. Ch.* [3] 3, 181). Slightly efflorescent. Gives off aq at 100°. Less soluble than tartaric acid. In dilute solutions of racemic acid the lowering of the freezing-point is the same as with an equal weight of tartaric acid (Raoult, *Z. Ph.* 2, 186). Absorption of a solution of racemic acid by filter paper does not separate the dextro- and lævo-acids (March-

lewski, *B.* 26, 983). A solution of racemic acid is ppd. by $CaSO_4$ (unlike tartaric acid). Calcium racemate is insol. acetic acid (unlike calcium tartrate). NH_4Cl does not hinder the ppn. of calcium racemate. When heated above 200° racemic acid yields the same products as tartaric acid. By various ferments (e.g. *Penicillium glaucum*) racemic acid, when fresh or as acid ammonium salt, is converted into tartaric acid (Pasteur; cf. E. Mulder, *R. T. C.* 1, 231). A solution in HNO_3 (S.G. 1.52) poured into half its volume of H_2SO_4 deposits the crystalline $C_2H_2(O.NO)_2(CO_2H)_2$ (Dessaingnes, *J. Ph.* [3] 32, 46). $AcCl$ converts racemic acid into di-acetyl-racemic anhydride $C_2H_2(OAc)_2C_2O_3$ [123°]. Racemic acid and its salts are inactive to light.

Salts (Fresenius, *A.* 41, 1; 53, 230).— $(NH_4)_2A''$. Trimetric prisms; $a:b:c = .509:1:847$. V. sol. water, nearly insol. alcohol. Give off NH_3 in air.— $(NH_4)HA''$. S. 1 at 20°; less sol. boiling water. Monoclinic prisms. Reddens litmus.— K_2A'' 2aq. Six-sided tables. S. 103 at 25°. Nearly insol. alcohol.— KHA'' . S. .55 at 19°; .7 at 100°. Insol. alcohol.— $K(NH_4)A''$. Striated prisms.— Na_2A'' . S. 38 at 25°. Trimetric prisms. Insol. alcohol.— $NaHA''$ aq. S. 9 at 19°. Monoclinic prisms (from water). Ppd. from aqueous solution by addition of alcohol.— $Na(NH_4)A''$ aq. S.G. 1.740 (Wyruboff, *A. Ch.* [6] 9, 229).— $NaKA''$ 4aq. S. 47 at 6° (Fresenius, *A.* 53, 230).— $NaKA''$ 3aq. Monoclinic crystals (Wyruboff, *A. Ch.* [6] 9, 232).— RbA'' .— CaA'' 4aq. Acicular prisms (Anschütz, *A.* 226, 191).— BaA'' 2½aq. S. .05. Crystalline pp.— SrA'' 4aq.— TlA'' (De la Provostaye, *A.* 126, 79).— $LiTlA''$ 2aq (Wyruboff).— $NaTlA''$ 2aq. S. 25 at 25°.— MgA'' 5aq. S. .85 at 19°.— CdA'' (Schiff, *A.* 104, 326).— PbA'' (dried at 100°).— $Pb_2C_4H_4O_6$ (Krug, *J.* 1861, 367).— CuA'' 2aq. Pale-blue needles, sol. alkalis and solution of Na_2CO_3 .— $Na_2CuC_4H_4O_6$ 4aq.— MnA'' aq.— NiA'' aq.— $NH_4(AsO)_2A''$ ½aq. S. 9.4 at 15°. Efflorescent crystals.— $K(AsO)_2A''$ 1½aq. S. 13 at 16°. Decomposed by hot water with liberation of As_2O_3 .— $Na(AsO)_2A''$ 2½aq. S. 7 at 19°. Non-efflorescent white crystals (Werther, *J. pr.* 32, 385).— $K(SbO)_2A''$ ½aq. Monoclinic prisms.— Ag_2A'' . Shining scales, less sol. aq than silver tartrate.

Mono-methyl ether $MeHA''$. Formed by evaporating racemic acid with $MeOH$ (Guérin-Varry, *A. Ch.* [2] 62, 77; *A.* 22, 252). Rectangular prisms, v. e. sol. cold water. Decomposed by hot water into the parent substances.— $KMeA''$ ½aq. Prisms.— $Ba(MeA'')_2$ 4aq. Monoclinic prisms.— $AgMeA''$. Pp.

Di-methyl ether Me_2A'' . [85°]. (282° i.v.). Formed by methylation of racemic acid, and also by mixing equal weights of the di-methyl ethers of the lævo- and dextro-tartaric acids (Anschütz a. Pictet, *B.* 18, 1178; 18, 1897; *A.* 247, 116). Monoclinic crystals; optically inactive. Yields a di-acetyl derivative $C_2H_2(OAc)_2(CO_2Me)_2$ [86°] in trimetric crystals; $a:b:c = .8095:1:6728$. This compound, examined by Raoult's method, has the same molecular weight as the di-acetyl derivative of di-methyl tartrate.

Mono-ethyl ether $EtHA''$. Deliquescent prisms, v. sol. alcohol. Inactive to light.— $KEtA''$ aq.— $Ba(EtA'')_2$ 2aq.— $AgEtA''$. Prisms.

Di-ethyl ether Et₂A". (238° cor. at 197 mm.) S.G. $\frac{1}{4}$ 1.2098; $\frac{3}{4}$ 1.2021. M.M. 8.759 at 15.5° (Perkin, C. J. 51, 364). Yields an oily acetyl derivative and a di-acetyl derivative C₂H₅(OAc)₂(CO₂Et)₂. [51°] (230° at 100 mm.). BzCl forms C₂H₅(OH)(OBz)(CO₂Et)₂ [57°]. The compound C₂H₅(OEt)₂(CO₂Et)₂ (147° at 15 mm.) is formed from di-bromo-succinic ether [58°] and NaOEt (Michael, J. pr. [2] 46, 234). — Ag₂A". — AgHA". Monoclinic, *a*:*b*:*c* = 721:1:869; β = 70° 10'.

Inactive tartaric acid
CO₂H.CH(OH).CH(OH).CO₂H. *Mesotartaric acid*. [140°–143°]. S. 125 at 15°.

Formation.—1. By heating cinchonine tartrate or racemate for several hours at 170° (Pasteur, A. 88, 212). The product is mixed with CaCl₂, which ppt. calcium racemate, and the filtrate slowly deposits calcium inactive tartrate.—2. By boiling tartaric or racemic acid for 400 hours with HClAq (Dessaignes; Pasteur, Bl. 1862, 107).—3. By heating tartaric acid (30 g.) or racemic acid with water (4 c.c.) for 2 days at 165°. Separated by means of its very soluble acid K salt (Jungfleisch, Bl. [2] 19, 101).—4. A product of the action of HNO₃ on sorbin (Dessaignes, C. R. 55, 769), erythrite (Przybytek, B. 17, 1412; Bl. [2] 43, 126) and glycerin.—5. By oxidation of lævulose (Kiliani, B. 14, 2530).—6. By oxidation of phenol by alkaline KMnO₄ at 0° (Doebner, B. 24, 1755).—7. A product of the action of moist Ag₂O on di-bromo-succinic acid. 8. By the action of nitrous acid on di-amido-succinic acid (Lehrfeld, B. 14, 1819).—9. By oxidation of maleic acid by alkaline KMnO₄ (Kekulé a. Anschütz, B. 14, 713).

Properties.—Prisms (containing aq). Loses its aq at 100°; at 200° it yields pyrotartaric and racemic acids. Prolonged boiling with HCl aq converts it into racemic acid (Dessaignes). The conversion is also effected by heating the acid with a little water at 175°. The ether is converted by AcCl into C₂H₅(OAc)₂(CO₂Et)₂ [48°], crystallising in silky needles.

Salts KHA". Needles. S. 12.5 at 19°. — RbHA" $\frac{1}{2}$ aq. — Rb₂A" aq. — RbNaA" 2 $\frac{1}{2}$ aq. — CaA" 3 aq. S. 17 at 100°. S. (HOAc) 0.28 at 18°; 0.85 at 100°. — PbA" aq: amorphous pp. — ZnA" 2 aq (dried at 110°). — TIHA". — TIA". — NaTIA" 2 $\frac{1}{2}$ aq. — Ag₂A" aq: white pp.

Metatartaric acid (C₂H₃O₆)₂. A deliquescent, glassy mass, v. sol. water, obtained by melting tartaric acid (Braconnot, A. Ch. [2] 68, 299; Erdmann, A. 21, 9; Laurent a. Gerhardt, A. 70, 848). It is sometimes formed when a solution of tartaric acid is evaporated over a water-bath (Grosjean, C. J. 43, 354). Converted by boiling water into tartaric acid.

Salts.—(NH₄)HA". Minute needles. More soluble than the acid ammonium tartrate. Its solution is ppd. by CaCl₂ and NH₄Aq only when highly concentrated. CaA" 4 aq. Minute lenticular grains, sol. dil. HClAq, converted by boiling water into calcium tartrate.

Ditartaric acid C₂H₂O₁₁. An anhydride of tartaric acid, got by heating tartaric acid at 170° till it is no longer ppd. by lime-water (Fremy, A. 19, 197; 29, 142; 78, 297). Amorphous and very deliquescent. Sol. alcohol, insol. ether. Its salts are amorphous, v. sol. water, and ppd.

by alcohol. They are converted into meta-tartrates, and finally into tartrates, by boiling water.—CaA". — BaA". — PbA". — CuA". — Ag₂A". V. sol. water (Schiff, A. 125, 129).

Ethyl ether Et₂A". Fat-like solid.

Tartrellic acid C₂H₂O₈. *Soluble tartaric anhydride*. Formed by quickly heating small quantities of tartaric acid till the fused mass swells up. Yellowish deliquescent mass, sol. water, forming an acid solution, from which CaCl₂ ppts. CaA', as an amorphous mass, which becomes crystalline on adding alcohol. Tartrellic acid is converted into tartaric acid by boiling water.

Insoluble tartaric anhydride C₂H₂O₈. Formed by heating tartaric acid for some time at 150° and exhausting the product with cold water. Powder, insol. water, alcohol, and ether. Converted by hot water into tartaric acid.

TARTRONIC ACID C₂H₂O₈, *i.e.* CH(OH)(CO₂H)₂. *Oxy-malonic acid*. Mol. w. 120. [187°]. Heat of solution — 4331 (Gal a. Werner, Bl. [2] 46, 808).

Formation.—1. By spontaneous decomposition of nitro-tartaric acid in aqueous solution (Dessaignes, C. R. 34, 731; 38, 44).—2. By the reduction of mesoxalic acid by sodium-amalgam (Baeyer, J. 1864, 641).—3. By the action of Ag₂O on bromo-malonic acid (Petrieft, B. 11, 414).—4. By boiling chloro-malonic ether with KOHAq, the yield being 25 p.c. of the theoretical amount (Conrad a. Bischoff, A. 209, 222).—5. From di-bromo-pyruvic acid and baryta-water at 40° (Grimaux, B. 10, 903).—6. From glyoxylic acid by treatment with KCy, the resulting nitrile being saponified (Böttiger, B. 14, 729).—7. A product of the action of alkaline cupric solution on glucose (Claus, Z. [2] 5, 152; A. 147, 114).—8. By slow oxidation of glycerin (Sadtler, B. 8, 1456; Campani a. Bizzari, G. 12, 1).—9. By heating sodium carboxy-tartronate (Gruber, B. 12, 514).

Preparation.—1. By boiling the di-nitrate of tartaric acid (20 g.) with alcohol (60 g. of S.G. .925) (Demole, B. 10, 1778).—2. By warming tri-chloro-lactic ether CCl₃CH(OH).CO₂Et with a 10 p.c. solution of NaOHAq (5 mols.), neutralising with HOAc and ppg. with BaCl₂ (Pinner B. 18, 752, 2852).

Properties.—Prisms (containing $\frac{1}{2}$ aq), v. sol. water and alcohol, sl. sol. ether. After drying at 100° it loses its water of crystallisation and becomes v. sol. ether. Massol (C. R. 114, 422) obtained anhydrous crystals [155°]. Decomposed by fusion, yielding CO₂ and glycolide C₂H₂O₄. Reduced by HIAq to malonic acid.

Salts.—Na₂A" (dried at 100°). V. sol. water. — K₂A" aq. — (NH₄)₂A". Needles. — (NH₄)HA". Yields glycollic amide on heating. — BaA" 2 aq. Micro-crystalline powder, v. sl. sol. water (Pinner). — BaA" aq (G.). — CaA" 2 $\frac{1}{2}$ aq (P.). — CaA" aq (C. a. B.). — CdA". — PbA" (dried at 120°). — MnA". — Ag₂A". Needles (from hot Aq).

Ethyl ether Et₂A". (c. 224°). Heavy oil (Freund, B. 17, 786; Pinner).

The acetyl derivative CH(OAc)(CO₂Et)₂ (c. 161° at 60 mm.), S.G. $\frac{15}{16}$ 1.131, is formed from bromo-malonic ether and KOAc in EtOH at 50° (Conrad a. Brückner, B. 24, 2997). Br converts it into mesoxalic ether C(OH)₂(CO₂Et)₂ [57°].

Amide $\text{CH}(\text{OH})(\text{CO.NH}_2)_2$. [196°]. Six-sided plates, m. sol. hot water.

Amic acid $\text{CO}_2\text{H.CH}(\text{OH}).\text{CO.NH}_2$. [160°]. Formed by boiling sodium dialurate with water (Menschutkin, *A.* 182, 82). Needles, sl. sol. cold water. Converted by nitrous acid into glycollic acid.— KA' aq.— BAa' aq.— PbA'_2 aq. Needles, v. sol. hot water.— AgA' . Needles.

Phenyl derivative $\text{CH}(\text{OPh})(\text{CO}_2\text{H})_2$. Formed by saponification of its ether $\text{CH}(\text{OPh})(\text{CO}_2\text{Et})_2$ (230°–240° at 60 mm.), which is got from bromo-malonic ether, phenol, and NaOEt (C. a. B.). At 196° it forms $\text{CH}_2(\text{OPh}).\text{CO}_2\text{H}$.

TARTRONYL-UREA v. DIALURIC ACID.

TAURINE $\text{C}_2\text{H}_7\text{NSO}_3$, i.e.

$\text{CH}_2(\text{NH}_2).\text{CH}_2.\text{SO}_3\text{H}$. *Amido-ethane sulphonic acid*. Mol. w. 125. S. 6.5 at 12°. H.F. 185,700 (Berthelot a. Matignon, *A. Ch.* [6] 22, 182). Obtained by the action of acids and alkalis on taurocholic acid (Gmelin, *Tiedemann a. Gmelin's Die Verdauung*, 1, 43; Demarçay, *A.* 27, 286; Dumas a. Pelouze, *A.* 27, 292; Redtenbacher, *A.* 57, 170; Strecker, *A.* 65, 132; 67, 34; 91, 101). Occurs in the free state in putrid bile and in the muscles of the oyster, in shark's blood, in the liver, spleen, and kidneys of the ray, and in the lungs of oxen (Valenciennes a. Fremy, *C. R.* 41, 735; Städeler a. Frerichs; Clöetza, *A.* 99, 289). Formed also by heating β -chloro-ethane sulphonic acid with NH_3 aq at 100° (Kolbe, *A.* 122, 33), and by the action of SO_2 on vinylamine (Gabriel, *B.* 21, 2667). Prepared by evaporating ox-bile with dilute HCl at 100°, decanting from a resin, allowing to crystallise, and re-crystallising from water. It may be purified by means of the lead salt.

Properties.—Transparent crystals, m. sol. water, insol. alcohol. Neutral to litmus. Not melted below 240°. Converted by nitrous acid into isethionic acid (Gibbs, *Am. S.* [2] 25, 30). Decomposed by potash-fusion.

Salts.— NaA' . Very deliquescent (Lang, *Bl.* [2] 25, 180).— CaA'_2 . Slender needles, v. e. sol. water.— PbA'_2 . Needles, v. e. sol. water.— $\text{PbA}'_2(\text{OH})_2$.— CdA'_2 .— HgA'_2 .— $\text{Hg}_2\text{A}'_2\text{O}$ (Engel, *Bl.* [2] 28, 532).— AgA' .

Benzoyl derivative $\text{NHBz.C}_2\text{H}_4.\text{SO}_3\text{H}$. Formed by heating μ -phenyl-thiazole tetrahydride with HCl and bromine-water (Gabriel a. Heymann, *B.* 23, 159). Syrup.— AgA' . Spherical groups of plates.

Phthalyl derivative $(\text{C}_6\text{H}_4\text{O})_2\text{N.CH}_2\text{CH}_2.\text{SO}_3\text{H}$. Got by oxidising di-phthalimido-di-ethyl-disulphide with HNO_3 (S.G. 1.25) (Gabriel, *B.* 24, 1116). Crystals (containing $1\frac{1}{2}$ aq), sol. EtOAc . Tastes bitter.

Imide $\text{C}_2\text{H}_4\text{SO}_2$. [45°–50°]. Prepared from β -chloro-ethane-sulphonic chloride $\text{CH}_2\text{Cl.CH}_2.\text{SO}_2\text{Cl}$ by treatment with ammonia (James, *C. J.* 49, 491). Solid, resembling gum arabic; bitter in taste. V. sl. sol. cold, v. sol. hot, water, insol. alcohol and ether. Ppd. HgO appears to form the compound $(\text{C}_2\text{H}_4\text{SO}_2\text{N})_2\text{Hg}$.

Ethyl-taurine v. ETHYL-AMIDO-ETHANE SULPHONIC ACID.

Methyl-taurine v. METHYL-AMIDO-ETHANE SULPHONIC ACID.

TAUROCHENOCHOLIC ACID $\text{C}_{26}\text{H}_{47}\text{NSO}_6$. Occurs as K and Na salts in goose-bile (Heintz

a. Wislicenus, *P.* 108, 547; Otto, *A.* 149, 192). Amorphous, sol. water and alcohol. Decomposed by boiling with baryta or potash into taurine and chenocholic acid.— NaA' aq (dried at 110°). Small tables. Its aqueous solution gives pps. with CaCl_2 , AgNO_3 , and lead subacetate, but not with lead acetate.

TAUROCHOLIC ACID $\text{C}_{26}\text{H}_{47}\text{NSO}_6$. Occurs as Na salt in the bile of most animals (Strecker, *A.* 67, 80; 70, 169; Hüfner, *J. pr.* [2] 19, 302; Copeman a. Winston, *J. Physiol.* 10, 213). Obtained by ppg. with lead acetate, filtering from lead glycocholate, and ppg. lead taurocholate by lead subacetate. Deliquescent silky needles, v. sol. water and alcohol, m. sol. ether. Dextrorotatory, $[\alpha]_D = 25^\circ$ (Hoppe-Seyler, *Arch. Path. Anat.* 15, 126). Boiling water splits it up into taurine and cholic acid. Antiseptic, and ppts. albumen completely from its solutions (Maly, *M.* 4, 89).

Salts.— NaA' (dried at 120°). Ppd. by alcohol in an amorphous state, rendered crystalline by ether.— KA' . Needles, resembling wavellite.

TAUROCYAMINE $\text{C}_{26}\text{H}_{47}\text{N}_2\text{SO}_6$, i.e. $\text{NH}_2(\text{CNH}_2).\text{NH.CH}_2\text{CH}_2.\text{SO}_3\text{H}$. [226°]. S. 4 at 21°. Formed by heating taurine with cyanamide (1 mol.) and water at 110° (Engel, *B.* 8, 1597; Dittrich, *J. pr.* [2] 18, 63). Small white prisms, v. sol. water, insol. alcohol and ether. From cold water it crystallises with aq.

TAXINE $\text{C}_{26}\text{H}_{47}\text{NO}_{10}$. [82°]. Obtained from the leaves, twigs, and fruit of the yew (*Taxus baccata*) by extracting with ether (Lucas, *Ar. Ph.* [2] 85, 145; Van der Harst, *R. T. C.* 3, 279; Marmé, *Bl.* [2] 26, 417; Hilger a. Brande, *B.* 23, 464). The ethereal solution is quickly shaken with acidulated water, and the solution ppd. by NH_3 aq. Crystalline. Gives off aromatic fumes on melting. V. sl. sol. water, v. sol. alcohol and ether, insol. benzene. Conc. H_2SO_4 gives a deep purple; Fröhde's reagent a reddish-violet colour. Gives yellow pps. with sodium phosphomolybdate, I in KI, and potassium bismuth iodide. Insol. alkalis. The salts crystallise with difficulty.—Salts: $\text{B}'\text{HCl}$.— $\text{B}'_2\text{H}_2\text{SO}_4$.— $\text{B}'_2\text{H}_2\text{PtCl}_6$.— $\text{B}'\text{HAuCl}_4$.— $\text{B}'\text{EtI}$.

TECTOQUINONE. [171°]. Obtained from teak resin or by the distillation of teak wood (Romanis, *C. J. Proc.* 4, 116). Amber-yellow crystals, sol. alcohol. Reduced by zinc-dust and HOAc to $\text{C}_{16}\text{H}_{22}$. Yields a nitro-derivative and a bromo-derivative [165°].

TELLURATES. Salts of telluric acid, H_2TeO_4 (g.v., p. 649). The normal tellurates of monovalent metals have the composition $\text{M}_2\text{TeO}_4.x\text{H}_2\text{O}$; there are also acid tellurates $\text{MHTeO}_4.x\text{H}_2\text{O}$; and two classes of tetratellurates, (1) $\text{M}_2\text{Te}_4\text{O}_{13}.x\text{H}_2\text{O}$, which are soluble in water when M is an alkali metal, and (2) $\text{M}_2\text{Te}_4\text{O}_{13}$, which are insoluble in water. The hydrated tetratellurates may be represented as acid ditellurates derived from the hypothetical acid $\text{H}_2\text{Te}_4\text{O}_{13}$; thus $\text{K}_2\text{Te}_4\text{O}_{13}.4\text{H}_2\text{O} = 2\text{KHTe}_4\text{O}_{13}.3\text{H}_2\text{O}$. Some acid salts may be represented as derived from hypothetical ditelluric acid, e.g.

$\text{PbTe}_4\text{O}_{13}$ (= $\text{PbTeO}_4.\text{TeO}_2$).

The normal alkali tellurates are obtained by saturating H_2TeO_4 with MOHAq or $\text{M}_2\text{CO}_3\text{Aq}$ and crystallising. Alkali acid tellurates, and hydrated tetratellurates, are obtained by inter-actions of acids with the normal tellurates; anhydrous (insoluble) tetratellurates of the alkali

metals are formed by heating the acid tellurates; thus $6\text{KHTeO}_4 = \text{K}_2\text{Te}_2\text{O}_7 + 2\text{K}_2\text{TeO}_4 + 3\text{H}_2\text{O}$. Most of the other tellurates are obtained from the alkali salts by double decomposition.

The alkali tellurates, other than those of the form $\text{M}_2\text{Te}_2\text{O}_7$, are soluble in water; most of the other tellurates are insoluble or sparingly soluble in water. Tellurates generally dissolve easily in HClAq ; the solutions are not ppd. by water, but on boiling the solutions become yellow, give off Cl , and then yield a pp. of H_2TeO_4 on addition of water. Acidulated solutions of tellurates are slowly decomposed by H_2S , probably with ppn. of TeS_2 (*v. TELLURIUM SULPHIDES*, p. 655). Solutions of tellurates are slowly reduced by SO_2 , more quickly on heating, with separation of Te . When tellurates are heated to redness they give off O and form tellurites; heated with K_2CO_3 and charcoal, they give K_2Te .

The tellurates have been examined chiefly by Berzelius (*P.* 82, 577); and some of them also by Oppenheim (*J. pr.* 71, 267).

Potassium tellurates. The normal salt K_2TeO_4 , 5aq is obtained by dissolving H_2TeO_4 and K_2CO_3 in the ratio $\text{H}_2\text{TeO}_4:\text{K}_2\text{CO}_3$ in hot water and crystallising; also by dissolving H_2TeO_4 in excess of KOH , heating, and allowing to cool slowly. Crystallises in rhombic prisms, isomorphous with K_2SO_4 (Handl, *J.* 1861, 266). The crystals become moist in air and form KHTeO_4 , 3aq and K_2CO_3 . The acid salt 2KHTeO_4 , 3aq separates on adding to K_2TeO_4 , 5aq sufficient H_2SO_4 , or other strong acid, to remove half the potassium; the salt is crystallised from hot water. This salt is slightly soluble in cold water, but much more soluble in hot water; when heated it is converted into K_2TeO_4 and $\text{K}_2\text{TeO}_{13}$. The tetratellurate $\text{K}_4\text{Te}_4\text{O}_{13}$ is obtained, as a yellow powder, by heating 2KHTeO_4 , 3aq below redness and washing out K_2TeO_4 in water. $\text{K}_4\text{Te}_4\text{O}_{13}$ is insoluble in water, also in HClAq or HNO_3Aq except after prolonged boiling. The hydrated tetratellurate $\text{K}_4\text{Te}_4\text{O}_{13}\cdot 4\text{H}_2\text{O}$ —which may also be regarded as an acid ditellurate $2\text{KHTeO}_4\cdot 3\text{H}_2\text{O}$ —is formed by adding $\text{H}_2\text{SO}_4\text{Aq}$, or another strong acid, to $\text{K}_2\text{TeO}_4\text{Aq}$ in quantity to remove 6K from $4\text{K}_2\text{TeO}_4$ ($4\text{K}_2\text{TeO}_4\text{Aq} + 3\text{H}_2\text{SO}_4\text{Aq} = \text{K}_4\text{Te}_4\text{O}_{13}\text{Aq} + 3\text{H}_2\text{O} + 3\text{K}_2\text{SO}_4\text{Aq}$), and crystallising. The salt is fairly soluble in cold water; it is partly decomposed to KHTeO_4 and $\text{H}_2\text{TeO}_4\text{Aq}$ by repeatedly crystallising in aqueous solution.

The following tellurates have been described (Berzelius, *l.c.*; Oppenheim, *l.c.*): **Ammonium salts** $(\text{NH}_4)_2\text{TeO}_7$, $(\text{NH}_4)_2\text{Te}_2\text{O}_7$, $(\text{NH}_4)_4\text{Te}_4\text{O}_{13}$, obtained by ppg. solutions of the corresponding salts of K or Na with NH_4Cl . **Barium salts** BaTeO_4 , 3aq, $\text{BaH}_2(\text{TeO}_4)_2$, 2aq, BaTe_2O_7 , obtained by ppn. **Cadmium salt** CdTeO_4 , obtained by ppn. **Calcium salt** CaTeO_4 , obtained by ppn. **Lead salts** PbTeO_4 , PbTe_2O_7 , $\text{PbTe}_4\text{O}_{13}$, by ppn; a basic salt is also said to exist. **Silver salts** Ag_2TeO_4 , and several basic salts $x\text{Ag}_2\text{O}\cdot y\text{TeO}_2$. **Sodium salts** Na_2TeO_4 , 3aq, NaHTeO_4 , 3aq, NaH_2TeO_4 , 3aq, and $\text{Na}_2\text{Te}_2\text{O}_7$, obtained similarly to the potassium salts. Tellurates of Al , Cr , Co , Cu , Fe , Li , Mg , Mn , Hg , Ni , and Sr have also been described, but only very superficially.

M. M. P. M.

TELLURHYDRIC ACID H_2Te ; *v. HYDROGEN TELLURIDE*, vol. ii. p. 727.

TELLURIC ACID H_2TeO_4 ; crystallises from solutions as $\text{H}_2\text{TeO}_4\cdot 2\text{H}_2\text{O}$.

Formation.—1. By oxidising Te by *aqua regia*.—2. K_2TeO_4 is formed by the interaction of Cl with $\text{K}_2\text{TeO}_4\text{Aq}$, also by fusing TeO_2 with KNO_3 or KClO_4 .

Preparation.—1. A mixture of TeO_2 , KClO_4 , and KOH , in the ratio $\text{TeO}_2:2\text{KClO}_4:2\text{KOH}$ is thoroughly fused; the fused mass is dissolved in water and BaCl_2Aq is added; the pp. of BaTeO_4 is purified by recrystallisation from hot water, and is then dried at 100° ; the dry BaTeO_4 is mixed with its own weight of water and one-fourth its weight of conc. H_2SO_4 , and heated till decomposition is complete, when BaSO_4 is removed by filtration, and the filtrate is evaporated at 100° to the crystallising point; the crystals that separate are dried, powdered, washed repeatedly with alcohol to remove H_2SO_4 , and recrystallised from water (Oppenheim, *J. pr.* 71, 267). Berzelius (*P.* 28, 392; 32, 1) fused TeO_2 with an equal weight of K_2CO_3 or Na_2CO_3 , dissolved in water, added KOH equal to the weight of TeO_2 used, passed in Cl until the liquid smelt strongly thereof, ppd. by BaCl_2Aq , and proceeded as described above.—2. TeO_2 is dissolved in HNO_3Aq , the solution is boiled with PbO , and filtered, Pb is ppd. from the filtrate by $\text{H}_2\text{SO}_4\text{Aq}$, the filtrate from PbSO_4 is evaporated to dryness at 100° , the residue is digested with alcohol and ether to remove H_2SO_4 , and is then crystallised from hot water *in vacuo* (Becker, *A.* 180, 257).

Properties and Reactions.— $\text{H}_2\text{TeO}_4\cdot 2\text{H}_2\text{O}$ is obtained by slow crystallisation in white, monoclinic crystals, resembling gypsum, S.G. 2.9999 at 25.5° (Clarke, *Am. S.* [3] 16, 401). When obtained by rapid evaporation $\text{H}_2\text{TeO}_4\cdot 2\text{H}_2\text{O}$ appears as a glassy solid. Heated to $c. 130^\circ$ H_2TeO_4 is obtained; decomposition begins at a little above 160° to TeO_2 and H_2O , and at $c. 180^\circ$ TeO_2 begins to decompose to TeO and O , this decomposition being complete at $c. 350^\circ$ (Wills, *C. J.* 35, 704). H_2TeO_4 has S.G. 3.425 at 18.8° (Clarke, *l.c.*). $\text{H}_2\text{TeO}_4\cdot 2\text{H}_2\text{O}$ is slightly soluble in cold water; it is dissolved fairly easily by boiling water; soluble in acid and alkali solutions; almost, if not quite, insoluble in alcohol. H_2TeO_4 dissolves very slowly in boiling water. Aqueous solutions of H_2TeO_4 have a metallic, not a sour, taste; they very slightly redden litmus. Thomsen (*Th.* 2, 277) gives the following H.F.: [TeO_4Aq] = 98,380; [TeO_4AqO] = 21,200. H_2TeO_4 dissolves gradually in hot, fairly conc. HClAq , with evolution of Cl and formation of $\text{H}_2\text{TeO}_4\text{Aq}$. $\text{H}_2\text{TeO}_4\text{Aq}$ is not reduced by passing H_2S into it, but if the solution is saturated with H_2S and kept in a warm place, in a closed flask, for some time, the liquid becomes brown, and flakes, probably of TeS_2 (*v. TELLURIUM SULPHIDES*, p. 655), are deposited.

$\text{H}_2\text{TeO}_4\text{Aq}$ reacts with alkalis to form salts M_2TeO_4 and MHTeO_4 ; salts of the forms MHTe_2O_7 and $\text{M}_2\text{Te}_2\text{O}_7$ are also known (*v. TELLURATES*, p. 648).

M. M. P. M.

TELLURIDES. Any compound of Te with a single element more positive than itself is called a telluride. Tellurides of the heavier metals are generally formed by melting the metals with Te , also by passing H_2Te into solutions of salts of the metals; tellurides of K and Na are formed

by heating TeO_2 with K_2CO_3 or Na_2CO_3 and charcoal; many tellurites and tellurates give tellurides when heated in a current of H. Te ppts. tellurides of Cu, Ag, and some other metals, by boiling solutions of salts of these metals with Te (Parkmann, *C. C.* 1862, 814). Tellurides of K and Na dissolve in water with a red colour; this colour is due either to polytellurides or to the presence of traces of oxides according to Demarçay (*Bl.* [2] 40, 99). Berthelot a. Fabre (*C. R.* 105, 92) obtained colourless solutions of alkali tellurides by passing pure H_2Te into solutions of alkalis; a trace of O produced a red colour and separated Te. Tellurides react with HClAq giving off H_2Te ; they are oxidised to tellurites by HNO_3Aq , and to tellurates and tellurates by *aqua regia*. Warmed in Cl tellurides give metallic chlorides and TeCl_4 .

Tellurides of Sb, As, Bi, Au, Fe, K, Ag, and Na are mentioned under these metals (*cf.* Brauner, *C. J.* 55, 388). M. M. P. M.

TELLURITES. Salts of tellurous acid H_2TeO_3 (*q. v.*, p. 656). The normal and acid tellurites of monovalent metals belong to the forms M_2TeO_3 and MHTeO_3 . Some salts are also known containing relatively more of the acidic radicle; these may be formulated as $\text{M}_2\text{O} \cdot x\text{TeO}_3$, where x is 2 and 4; or they may be regarded as $\text{M}_2\text{TeO}_3 \cdot x\text{TeO}_3$, where x is 1 and 3; or finally these hyperacid salts may be looked on as $\text{M}_2\text{Te}_2\text{O}_5$ and $\text{M}_2\text{Te}_3\text{O}_7$ —that is, as derivatives of the hypothetical acids $\text{H}_2\text{Te}_2\text{O}_5$ and $\text{H}_2\text{Te}_3\text{O}_7$.

Tellurites are generally formed by heating together basic oxides and TeO_2 in the proper proportions; some tellurites of the heavier metals are obtained by ppn. from solutions of alkali tellurites. Tellurites of the alkali metals dissolve readily in water; those of the alkaline earth metals are less soluble; the others are insoluble in water. Most tellurites dissolve in HClAq , forming yellow solutions which do not give off Cl on heating; this reaction distinguishes them from tellurates (*v. p.* 649). Solutions of tellurites in a little HClAq deposit H_2TeO_3 on dilution. Most tellurites are fusible, and crystallise on cooling; the hyperacid alkali tellurites form colourless glass-like solids after fusion. By strongly heating with charcoal and K_2CO_3 , most tellurites give K_2Te .

Tellurites of potassium. The normal salt K_2TeO_3 , and the acid salt $\text{K}_2\text{TeO}_3 \cdot \text{TeO}_2$ ($= \text{K}_2\text{Te}_2\text{O}_5$ or $\text{K}_2\text{O} \cdot 2\text{TeO}_3$) are prepared by fusing TeO_2 with K_2CO_3 in the proper proportions. K_2TeO_3 melts at a red heat; dissolves slowly in cold water, more quickly in boiling water; the aqueous solution has an alkaline taste and reaction, and is decomposed by the CO_2 in the air. $\text{K}_2\text{O} \cdot 2\text{TeO}_3$ melts below redness, and solidifies again to a transparent, colourless, crystalline mass; dissolved by boiling water, and the solution on cooling deposits $\text{K}_2\text{O} \cdot 4\text{TeO}_3$. The *tetratellurite* or *hyperacid tellurite* $\text{K}_2\text{O} \cdot 4\text{TeO}_3 \cdot 4\text{H}_2\text{O}$ ($= \text{K}_2\text{Te}_5\text{O}_{13} \cdot 3\text{H}_2\text{O}$ or $\text{K}_2\text{Te}_5\text{O}_{13} \cdot 4\text{H}_2\text{O}$) is prepared by boiling $\text{H}_2\text{TeO}_3\text{Aq}$ with K_2CO_3 and filtering at 100° ; the salt is deposited on cooling in microscopic six-sided prisms and tablets. This salt reacts with cold water to give a solution of K_2TeO_3 and $\text{K}_2\text{Te}_2\text{O}_5$, and a gelatinous pp. of H_2TeO_3 ; when heated $4\text{H}_2\text{O}$ is given off, and $\text{K}_2\text{O} \cdot 4\text{TeO}_3$ remains as a salt which melts at a

moderate red heat and solidifies on cooling to a colourless glass.

The tellurites have been examined chiefly by Berzelius (*P.* 32, 577; *v. also* Oppenheim, *J. pr.* 71, 267). Salts of the following metals have been isolated, but many have been studied in a very superficial way: Al, NH_3 , Ba, Cd, Ca, Cr, Co, Cu, Fe, Pb, Li, Mg, Mn, Hg, Ni, Ag, Na, Sr, and Zn. M. M. P. M.

TELLURIUM. Te. At. w. c. 125 (*v. infra*). Mol. w. c. 250 (*v. infra*). Melts at $c. 455^\circ$ (Carnelley a. Williams, *C. J.* 37, 125). Boils at $c. 1390^\circ$ (Deville a. Troost, *C. R.* 91, 83). S.G. $6 \cdot 2549$ at 0° (after compression); $6 \cdot 2322$ at 0° (uncompressed) (Spring, *B. B.* 5, 854); $6 \cdot 2549$ at $18 \cdot 2^\circ$ (after melting in H) (Pfiwoznik, *C. C.* 1892. ii. 962; for further data *v. Clarke's Table of Specific Gravities* [2nd ed.] 10). V.D. at $c. 1390^\circ$ to $c. 1440^\circ = 130$ (Deville a. Troost, *C. R.* 56, 891). S.H. (21° to 51° , crystalline) $\cdot 0475$ (Kopp, *T.* 1865, 71); (at 98° , crystalline) $\cdot 0483$; (at 98° , after distillation in SO_2) $\cdot 0518$ (Fabre, *A. Ch.* [6] 14, 101). C.E. (linear, at 0°) $\cdot 00001675$ (Pizeau, *C. R.* 68, 1125). E.C. $\cdot 000777$ at $19 \cdot 6^\circ$ (Ag at $0^\circ = 100$) (Matthiesen, *P.* 103, 428); conductivity increases slightly when light falls on Te; the increase is very much less than in the case of Se (*v. Adams a. Day, Pr.* 24, 163; 25, 113). E.C. decreases slightly to $c. 100^\circ$ – 140° , and then increases to 200° ; on cooling after fusion E.C. decreases regularly and markedly; the following values are given by Exner (*P.* 158, 625) $\cdot 0035$ at 200° , $\cdot 00286$ at 20° (after fusion), $\cdot 000435$ at 20° (after very slow cooling from fusion). Te crystallises in rhombohedra; $a:c = 1:1 \cdot 3298$; it is isomorphous with S and Se (*v. Muthmann, Z. P. C.* 8, 396). For emission-spectrum *v. Plücker a. Hittorf (Pr.* 13, 153); Thalen; Salet (*A. Ch.* [4] 28, 51); Ditte (*C. R.* 73, 622); Hartley a. Adeney (*T.* 1884 [1] 117). For absorption-spectrum of vapour of Te *v. Gernz (C. R.* 74, 1190). H.C. [TeO_3Aq] = $98,880$ (*Th.* 2, 278).

Historical.—Examining a mineral containing gold from the Seven Mountains in 1782 Müller von Reichenstein suspected the presence of a new metal (*Abhand. einer Privatgesellschaft in Böhmen*). He sent a specimen of the mineral to Bergmann, who said that it contained a metal which was not the same as that in blende. In 1798 Klaproth received some of the mineral from M. von R., and isolated the characteristic element, to which he gave the name tellurium (from *tellus* = the earth) (*K., Beiträge zur chem. Kenntniss der Mineralkörper*, 3, 1; *cf. Crell's Ann.* 1798, 91; and *G. A.* 12, 246). The compounds of Te were more fully examined by Berzelius (*S.* 6, 311; 34, 78; *P.* 8, 411; 28, 392; 32, 1, 577).

Occurrence.—Te is found native, in small quantities, and in a few localities—chiefly in Hungary and Transylvania, and in Virginia, U.S.; it generally accompanies Au and Ag; specimens have been obtained with 97–98 p.c. Te. Tellurides are also found in small quantities in Hungary, Mexico, California, Bolivia, and some other places; in considerable quantities in Colorado; these are generally compounds of Te with Bi, Ag, Pb, Bi and S, Ag and Au, Au, Pb and Sb; *tellurite* (or *tellurium-ochre*) containing TeO_3 is found in small quantities in the Seven Mountains (*v. G. Rose, P.*

18, 64; Rammelsberg, *J. M.* 1874. 80; Burkart, *J. M.* 1878. 476; Silliman & Marvine, *Am. S.* [8] 8, 25; Mathewson, *J. M.* 1866. 93; Genth, *J. M.* 1875. 188, 314).

Formation.—1. By passing SO_2 into $\text{H}_2\text{TeO}_3\text{Aq}$; $\text{H}_2\text{TeO}_3\text{Aq} + 2\text{SO}_2 + \text{H}_2\text{O} = 2\text{H}_2\text{SO}_4\text{Aq} + \text{Te}$. Also by ppg. solution of TeCl_4 in dilute HClAq , or of a Te compound in $\text{H}_2\text{SO}_4\text{Aq}$, by an alkali sulphite. 2. By reducing a boiling solution of $(\text{NH}_4)_2\text{TeO}_4\text{Aq}$ by grape sugar (Stolba, *J.* 1873. 214).—3. By decomposing K_2TeAq by air or oxygen (*v.* Oppenheim, *J. pr.* 71, 267; 81, 308; Himly, *J.* 1877. 213).—4. By ppn, by means of zinc, from solutions of Te compounds in $\text{H}_2\text{SO}_4\text{Aq}$ (*v.* Löwe, *J. pr.* 60, 163).

Preparation.—There are several methods of preparing crude Te from the minerals that contain it. Native bismuth telluride is made into a paste with oil and K_2CO_3 , and gradually heated to whiteness in a covered crucible; K_2Te is extracted from the fused mass by boiling water, and the solution deposits Te on standing in air. Or the mineral containing Te is powdered and treated with dilute HClAq ; the insoluble matter is gradually added to three times its weight of conc. H_2SO_4 , and heating is continued until SO_2 ceases to be given off; the solid that forms on cooling is dissolved in water containing a little HCl ; the solution is filtered from AgCl , Te is ppd. from the filtrate by zinc, and undissolved zinc is removed by digestion with dilute HClAq . For details and other methods *v.* Berzelius (*P.* 8, 411; 28, 392); Löwe (*J. pr.* 60, 163); Wöhler (*A.* 84, 69); Oppenheim (*J. pr.* 81, 308); Schnitzer (*D. P. J.* 211, 484, 492); Schwarz (*D. P. J.* 186, 29).

To prepare pure Te , Brauner (*C. J.* 55, 382; *cf. M.* 10, 411) recommends to digest the crude material with HClAq in a large flask, and to oxidise by HNO_3Aq added little by little till the solid matter becomes white, to evaporate several times with conc. HClAq (to remove HNO_3), and then to dilute cautiously with water, taking care not to add enough water to ppt. H_2TeO_3 along with any PbCl_2 which may come down. He then adds some saturated SO_4Aq , warms to $60^\circ\text{--}70^\circ$, and ppts. Te by passing SO_2 into the warm solution. The Te thus obtained generally contains a little copper and lead selenides. The pp. is dried and fused in small portions with KCy ; the fused mass, which contains K_2Te , is dissolved in water, from which air has been removed, in a stoppered flask; the liquid is allowed to clear (there is generally a small pp. of tellurides of heavy metals mixed with a trace of Te) and is then poured off, and a current of air is passed through it, whereby Te is ppd. The Te is dried, placed in a porcelain boat, which is introduced into a wide tube of hard glass surrounded by wire gauze, and distilled in a current of pure dry H . (For a method of purification based on the ppn. of Te from $(\text{NH}_4)_2\text{TeO}_4\text{Aq}$ by grape sugar, *v.* Stolba, *J.* 1873. 214).

Properties.—As prepared by sublimation in H , tellurium is a white, shining, crystalline, very brittle solid, unchanged by exposure to air. During distillation in H , Brauner (*l.c.*) noticed that some H_2Te was formed, and was decomposed with deposition of needle-shaped crystals of Te , some of which were 1 centim. in length. The crystals of Te are hexagonal rhombohedra, iso-

morphous with S and Se (*v.* Muthmann, *Z. P. C.* 8, 396). By allowing K_2TeAq to decompose in air, H. Rose obtained six-sided prisms with rhombohedral summits (*P.* 21, 443; *cf.* Fabre & Berthelot, *C. R.* 104, 1405). Amorphous Te is obtained as a brown powder by ppg. $\text{H}_2\text{TeO}_3\text{Aq}$ by SO_2 ; on warming, the amorphous variety changes to the crystalline, giving off a large quantity of heat (*F. A. B., l.c.*). Te that has been melted and cooled quickly seems to contain both the crystalline and the amorphous varieties. According to Fabre (*A. Ch.* [6] 14, 100), both varieties have practically the same S.H. at $c. 100^\circ$. Te melts at $c. 455^\circ$ and boils at $c. 1390^\circ$; the vapour is golden yellow. Heated in air it burns with a brilliant blue-green flame to white clouds of TeO_2 , which are poisonous; the smell, like that of decaying radishes, that is noticed on burning impure Te is due to the oxidation products of Se , which is commonly present in specimens of crude Te . Te dissolves in very conc. boiling KOH Aq , forming a red liquid that contains K_2TeO_3 and K_2Te ; on allowing to cool, or on adding water, the whole of the Te separates. HCl Aq is without action on Te ; conc. hot H_2SO_4 dissolves it slightly, but the Te separates on dilution; when heated strongly with conc. H_2SO_4 , Te dissolves to H_2TeO_3 with evolution of SO_2 . Te dissolves in SO_3 , forming TeSO_3 . Conc. HNO_3Aq forms a solution of H_2TeO_3 ; *aqua regia* forms H_2TeO_3 and some H_2TeO_4 . Molten KNO_3 produces K_2TeO_4 .

In its physical properties Te approaches the metals, and especially resembles Sb . In its chemical properties Te is, on the whole, non-metallic; but the oxide TeO_2 combines with certain anhydrides of strong acids to form salt-like compounds, and the oxide TeO is said to dissolve in $\text{H}_2\text{SO}_4\text{Aq}$, forming $\text{Te}(\text{SO}_4)_2$. Te is closely related to Se , and less closely to S ; it shows distinct analogies with Cr , Mo , W , and U (*v.* OXYGEN GROUP OF ELEMENTS, vol. iii. p. 705, and CHROMIUM GROUP OF ELEMENTS, vol. ii. p. 168). The atom of Te is divalent in the gaseous molecules TeH_2 and TeCl_2 , and tetravalent in the gaseous molecule TeCl_4 .

Atomic weight of tellurium. The at. w. of Te was determined by Berzelius in 1812, 1818, and 1832 by oxidising Te by HNO_3Aq and weighing the TeO_2 produced; he obtained values varying from 127.9 to 128.5 (*P.* 8, 24; 28, 395; 32, 16). In 1857 von Hauer analysed K_2TeBr_6 , and obtained values from 126.5 to 128.1 (*W. A. B.* 25, 135). In 1879 Wills determined the weight of TeO_2 obtained by oxidising Te by HNO_3Aq and by *aqua regia*, and he also made analyses of K_2TeBr_6 ; his results varied from 126.1 to 129.3 (*C. J.* 85, 704). In 1883 Brauner obtained numbers varying from 124.94 to 125.4, by oxidising Te to TeO_2 , by converting Te and TeO_2 into $(\text{TeO}_2)_2\text{SO}_3$, and by synthesising Cu_2Te (*J. R.* 1883. [1] 493; abstract in *B.* 16, 3055). In 1889 Brauner made a very careful revision of the at. w. of Te (*C. J.* 55, 382):—(i.) by oxidising Te to TeO_2 , he obtained values varying from 124.48 to 127.28; (ii.) by converting TeO_2 into $(\text{TeO}_2)_2\text{SO}_3$, the numbers varied from 124.7 to 129 (one result gave 185.9); (iii.) by conversion of Te into $(\text{TeO}_2)_2\text{SO}_3$, the numbers varied from 124.3 to 129.7; (iv.) by syntheses of tellurides of Ag , Cu , and Au , the numbers varied from 125.7

to 129.9; (v.) by analysis of TeO_2 , the value 127.2 was obtained, but only one satisfactory analysis was made; (vi.) by analyses of TeBr_4 , the numbers varied from 127.27 to 127.81. The results obtained by analysing TeBr_4 were more concordant than any obtained by the other methods; but the value 127.8 is almost .75 units greater than the at. w. of iodine; hence it seems as if the at. w. of Te is greater than that of I. But if this is so, Te must be separated from S, Se, and the chromium metals, which are placed in Group VI. in the periodic arrangement of the elements; and Te must be placed either with the halogens in Group VII. (I being put into Group VI.), or this element must find a place in Group VIII. (I remaining in Group VII., and an empty place being left in Group VI., Series 7). The chemical properties of Te show that it belongs to the same group as S and Se; and the chemical properties of I make it impossible to place that element elsewhere than with F, Cl, and Br.

Is tellurium a homogeneous body? Rather than doubt the applicability of the periodic law, Brauner made the hypothesis that tellurium is not a homogeneous body, but that it contains an admixture of foreign substances. He dissolved Te, and ppd. in fractions by SO_2 , fused the fractions with KCy, dissolved in water, and ppd. fractionally by a current of air; he then distilled each fraction in H, and converted it into TeBr_4 , and analysed each fraction. The values thus obtained for the at. w. of Te were almost identical, the mean being 127.33. Pure TeO_2 was then dissolved in HClAq , and the solution was ppd. in eight fractions by ammonia; the filtrate from the eighth fraction was ppd. by SO_2 in presence of HClAq ; after boiling off SO_2 from the filtrate from the ninth fraction, the liquid was saturated with H_2S , and the TeO_2 in solution was obtained, converted into Te, and this converted into TeBr_4 ; the at. w. thus obtained (in three experiments) was 127.32, the three experiments agreeing extremely well. Te was then fused, but not distilled, in a current of H; it was then converted into TeBr_4 , which was freed from TeBr_3 by fractional sublimation *in vacuo*, without converting the TeBr_4 into vapour, and analysed; the values obtained for the at. w. of Te differed very much, ranging from 128.5 to 137.4. From these results Brauner concluded that 'if tellurium, obtained by any process of fractionation whatever, be subjected to distillation in a current of hydrogen, and the tetrabromide be prepared from this by sublimation in a vacuum, its analysis always gives the same atomic weight for tellurium. . . . If, however, the tellurium be only fused in a current of an indifferent gas, and the tetrabromide be not sublimed, higher numbers will be obtained. . . . It is therefore very probable that on distilling tellurium in a current of hydrogen, and the tetrabromide in a vacuum, one constituent of tellurium escapes partly, the presence of which in the last cases renders the atomic weight higher.' Brauner prepared TeBr_4 by fusing TeBr_3 with excess of Te, and subliming either *in vacuo* or in a current of CO_2 ; the analyses of different specimens of TeBr_4 showed percentages of Br varying from 54.658 to 55.14; the percentage of Br calculated for $\text{Te} = 127.32$ is 55.6. Brauner concluded that 'tellurium is

not a simple substance.' This conclusion is still held by B. to be correct. In a private communication (January 1894) he says: 'I consider Te to be a mixture of two elements that cannot be separated by ordinary chemical means, not even by fractionation. It cannot, however, be shown that the at. w. of Te is about 125, for all attempts I have made in this direction have failed completely. All atomic weight determinations made by me, and others, giving values higher or lower than 127.8 are due, partly to impurities, but in most cases to some undetected source of error.'

Molecular weight of tellurium. Deville and Troost (*C. R.* 56, 891) found the V.D. of Te between $c. 1390^\circ$ and $c. 1440^\circ$ to be 130; this gives the mol. w. of $c. 260$. As the at. w. of Te is not known with certainty, it is not possible at present to correct the value deduced for the mol. w. from the determinations of V.D. The gaseous molecule of Te is diatomic.

Reactions and Combinations.—1. Heated in air, or oxygen, Te is burnt to TeO_2 .—2. Heated in excess of chlorine TeOCl_2 is produced; with bromine TeBr_4 is produced; with iodine the product is TeI_4 .—3. Te and sulphur can be melted together in all proportions; it is doubtful whether definite compounds are formed or not (*v. TELLURIUM SULPHIDES*, p. 655). Te and selenium can also be melted together in all proportions; no definite compound has been isolated.—4. Nitric acid forms H_2TeO_3 ; according to Klein and Morel (*Bl.* [2] 43, 198), cold HNO_3Aq first forms $4\text{TeO}_2 \cdot \text{N}_2\text{O}_5 \cdot \text{xaq}$ (*v. TELLURIUM DIOXIDE*, p. 655). *Aqua regia* produces a mixture of H_2TeO_3 and H_2TeO_4 .—5. Te dissolves in hot conc. *potash solution*, forming a red solution that contains K_2Te and K_2TeO_3 ; on addition of water Te separates ($2\text{K}_2\text{TeAq} + \text{K}_2\text{TeO}_3\text{Aq} = 3\text{K}_2\text{OAq} + 3\text{Te}$).—6. Fusion with *potassium nitrate* produces K_2TeO_4 .—7. Fusion with *potassium carbonate* produces a mixture of K_2Te and K_2TeO_3 .—8. Te dissolves in *sulphur trioxide*, forming TeSO_3 (*v. thio-oxide* under *TELLURIUM OXIDES*, p. 655).

Detection and Estimation.—Free Te is readily detected by fusing with charred cream of tartar and dissolving in water, whereby a red solution is obtained that deposits Te in dark-brown flakes on standing in air. Tellurous acid and tellurites dissolve in dilute HClAq , and addition of water ppts. white H_2TeO_3 ; SO_2 ppts. Te from solutions of tellurites in dilute HClAq or HNO_3Aq . Solutions of tellurates in acids give no pps. with water; solutions in HClAq give off Cl on boiling, being reduced to tellurites, and are then ppd. by water. For a test for Te based on the formation of red TeSO_3 by passing TeH_2 into $\text{H}_2\text{SO}_4\text{Aq}$ *v. Divers* and Shimose, *C. J.* 43, 329. Te is generally estimated by ppg. the element, from solution of H_2TeO_3 or a tellurite, by alkali sulphite, SO_2 , or grape sugar (Kastner, abstract in *C. J.* 29, 440; *cf.* Donath, abstract in *C. J.* 60, 242). In *C. J.* 59, 238, Brauner describes a method for the volumetric estimation of Te by KMnO_4Aq .

Tellurium, acids of; tellurhydric acid H_2Te (vol. ii. p. 727); *tellurous acid* H_2TeO_3 (this vol., p. 656); *telluric acid* H_2TeO_4 (this vol., p. 649). The existence of the potassium salt of HCNTe is probable (*v. TELLUROCYANIDES*, vol. ii. p. 353).

Tellurium, alloys of. The compounds of Te with metals are sometimes classed with the more definite alloys (*v. TELLURIDES*, p. 649).

Tellurium, antimonides of. *v. ANTIMONY*; *Combinations*, No. 7, vol. i. p. 283.

Tellurium, arsenides of. *v. ARSENIC*; *Combinations*, No. 6, vol. i. p. 303.

Tellurium, bromides of. Two bromides have been isolated, TeBr_2 and TeBr_4 ; both are formed by the direct combination of Te and Br. The bromides can be sublimed, under reduced pressure, without change. The V.D. of neither has been determined; but, from the analogy of TeCl_2 and TeCl_4 , the formulæ are probably molecular.

TELLURIUM DIBROMIDE TeBr_2 . Formula probably molecular, from analogy of TeCl_2 . Prepared by fusing TeBr_4 with excess of powdered Te, and subliming either *in vacuo* or in a current of dry CO_2 . A blackish-green crystalline mass; obtained in steel-grey needles by slow sublimation (Brauner, *C. J.* 55, 410). Melts c. 305° , and boils c. 343° (Carnelley, *Melting- and Boiling-point Tables*, 1, 21). TeBr_2 is very hygroscopic; it is decomposed by water to $\text{H}_2\text{TeO}_4\text{Aq}$ and HBrAq . Dissolves in tartaric acid solution, forming TeBr_4 and Te (Brauner, *l.c.*).

TELLURIUM TETRABROMIDE TeBr_4 . (*Telluric bromide*.) Formula probably molecular, from analogy of TeCl_4 . Prepared by shaking together powdered Te and Br, in the proportion Te:4Br , warming in a current of dry CO_2 , and then subliming *in vacuo* (for details and description of apparatus, *v. Brauner*, *C. J.* 55, 396). Forms a crystalline crust, which is fiery red when hot and orange coloured when cold. S.G. $\frac{15^\circ}{4} = 4.31$ (Brauner, *l.c.*, p. 407). Melts at c. 380° , and boils at 414° – 427° , according to Carnelley a. Williams (*C. J.* 35, 563; 37, 125). Dissolves in a little water without change; on dilution a colourless liquid is obtained, containing HBr and H_2TeO_4 ; crystals are obtained by evaporating over H_2SO_4 , and are said by Berzelius to be $\text{TeBr}_4 \cdot x\text{H}_2\text{O}$. By adding AgNO_3Aq to a solution of TeBr_4 in tartaric acid, Brauner (*C. J.* 55, 398) obtained AgBr and also crystalline scales probably $(\text{C}_4\text{H}_4\text{O}_6)_2\text{Ag}_2\text{O} \cdot \text{TeO}_2 \cdot 2\text{aq}$; this compound is called by B. *tellurium-silver tartar emetic* (*cf. Klein a. Morel*, *C. R.* 100, 1140). TeBr_4 forms double salts with alkali bromides. The salt $\text{TeBr}_4 \cdot 2\text{KBr}$ ($= \text{K}_2\text{TeBr}_6$) is prepared by dissolving the proper quantity of KBr in water, adding Te, running in Br, shaking till the Te is dissolved, filtering, and evaporating at 100° (Wills, *C. J.* 35, 711; *cf. von Hauer*, *W. A. B.* 25, 135). Dark-red, opaque, lustrous crystals; orthorhombic, $a:b:c = 1:1.4901:1.8658$ (W., *l.c.*); *cf. Wheeler* (*Am. S.* [3] 45, 267), where some other salts of the form M_2TeBr_6 are described.

Tellurium, chlorides of. Two compounds are known, TeCl_2 and TeCl_4 ; both have been gasified, and the formulæ of both are molecular. The chlorides are formed by the direct combination of their elements.

TELLURIUM DICHLORIDE TeCl_2 . Mol. w. c. 196. Powdered Te is heated in a distillation-flask in a stream of Cl until the Te is completely converted into TeCl_2 ; Te is added equal

in weight to the original quantity used, the whole is heated for a little time, an inverted condenser being attached to the flask, and the TeCl_2 is then distilled off at 320° – 380° (Michaelis *B.* 20, 2488). TeCl_2 is a black, amorphous solid melting at 175° (M., *l.c.*) to a black liquid. Carnelley a. Williams give m.p. as 209° (*C. J.* 37, 125). Boils at 327° (C. a. W., *l.c.*). The vapour of TeCl_2 is reddish, and gives a characteristic absorption-spectrum (M., *l.c.*). V.D. at 440° , in vapour of N, $= 98.2$ (M., *l.c.*). The vapour becomes yellowish in presence of air or O; TeO_2 and TeCl_4 are formed, and after continued heating these react to produce TeOCl_2 (M., *l.c.*). TeCl_2 absorbs moisture when exposed to the air, but does not fume; on addition of much water H_2TeO_4 is formed; HClAq forms Te, and TeO_2 which remains dissolved in the acid (M., *l.c.*).

TELLURIUM TETRACHLORIDE TeCl_4 . (*Telluric chloride*.) Mol. w. c. 269. Powdered Te is heated, in a distillation flask, in a stream of dry Cl until the solid becomes pale yellow, when it is distilled in a stream of dry CO_2 (Michaelis, *B.* 20, 1780). TeCl_4 is a colourless, crystalline solid, melting at 214° , and boiling without decomposition at 380° (M., *l.c.*; Carnelley a. Williams give the m.p. as 224° [*C. J.* 37, 125], and the b.p. as 414° [*C. J.* 35, 563]). V.D. 131 at 440° , 126 at 530° (M., *l.c.*). The vapour of TeCl_4 shows no absorption-spectrum (M., *B.* 20, 2488). TeCl_4 dissolves without change in dilute HClAq . It deliquesces in the air, cold water ppts. an oxychloride, and H_2TeO_4 is also formed; boiling water dissolves TeCl_4 , and H_2TeO_4 separates on cooling.

TeCl_4 combines with alkali chlorides to form salts $\text{TeCl}_4 \cdot 2\text{MCl} = \text{M}_2\text{TeCl}_6$; these salts are best obtained by adding MClAq to a slight excess of TeCl_4 dissolved in dilute HClAq and crystallising (*v. Wheeler*, *Am. S.* [3] 45, 267). The salts crystallise in regular yellow octahedra, without water. Weber (*P.* 104, 422) described a compound $\text{TeCl}_4 \cdot 3\text{AlCl}_3$, obtained by melting together TeCl_4 and AlCl_3 . TeCl_4 absorbs NH_3 , forming a greenish-yellow solid that is unchanged in air and has the composition $\text{TeCl}_4 \cdot 2\text{NH}_3$ (Espenschied, *A.* 113, 101).

Tellurium, fluorides of. Only one fluoride of Te has been isolated. The formula TeF_4 is probably molecular, from the analogy of TeCl_4 .

TELLURIUM TETRAFLUORIDE TeF_4 . (*Telluric fluoride*.) Prepared by dissolving H_2TeO_4 in HFAq , evaporating at 100° to a syrup, allowing to cool, separating the white nodules that are formed, and heating in a Pt basin (Högborn, *Bl.* [2] 35, 60). If carbonate or hydroxide of an alkali metal, or of Ba, is added to the solution of H_2TeO_4 in HFAq before evaporation, double salts of the forms $\text{TeF}_4 \cdot \text{MF}$ and $2\text{TeF}_4 \cdot \text{M}^2\text{F}_2$ are obtained; these salts are decomposed by water (H., *l.c.*).

Tellurium, haloid compounds of. These compounds belong to the forms TeX_2 and TeX_4 , where $\text{X} = \text{Cl}, \text{Br}$ or I ; the only fluoride that has been isolated is TeF_4 . The chlorides TeCl_2 and TeCl_4 have been gasified, and the formulæ are molecular; the formulæ of the other haloid compounds are also probably molecular. An iodide containing more I than TeI_4 —perhaps TeI_5 , corresponding with SI_5 —may exist in the

solution of H_2TeO_3 in HIAq . No compound corresponding with S_2Cl_2 , Se_2Cl_2 , Se_2Br_2 , and Se_2I_2 has been isolated. The haloid compounds of Te are more stable towards heat than the corresponding compounds of Se or S. The haloid compounds of Te are decomposed by water, giving H_2TeO_3 and HXAq ; cold water is said to ppt. an oxychloride from TeCl_4 . The compounds TeX_4 combine with the haloid compounds of the alkali metals to form salts M_2TeX_4 ; when $\text{X} = \text{F}$ the salts are said to be of the form MTeF_4 .

Tellurium, hydride of, TeH_2 v. HYDROGEN TELLURIDE, vol. ii. p. 727.

Tellurium, iodides of. Two iodides have been isolated, TeI_2 and TeI_4 ; a third—perhaps TeI_3 —may exist in the solution of H_2TeO_3 in HIAq . TeI_2 is formed by directly combining Te and I; TeI_4 is obtained by digesting H_2TeO_3 with HIAq .

TELLURIUM DI-IOXIDE TeI_2 . Prepared by gently warming a mixture of powdered Te and excess of I; may be sublimed as a black, crystalline crust; when strongly heated I is given off. Not changed by water, hot or cold (Berzelius, *Lehrbuch*, 5th edit., 3, 1139).

TELLURIUM TETRA-IOXIDE TeI_4 . (*Telluric iodide*.) Obtained by digesting powdered H_2TeO_3 with HIAq in a closed flask, whereby hard black granules are formed. Melts when heated, and gives off I. Boiling water causes decomposition, probably forming an oxyiodide. If a solution of H_2TeO_3 in HIAq is evaporated over H_2SO_4 and CaO.H_2 *in vacuo*, lustrous prisms are obtained that are perhaps a compound of TeI_4 and HI (B., *l.c.*). By dissolving alkali iodides in TeI_4 dissolved in dilute HIAq , and crystallising, black salts of the form M_2TeI_6 are formed in regular octahedra; the potassium salt contains $2\text{H}_2\text{O}$ and crystallises in monoclinic forms (Wheeler, *Am. S.* [3] 45, 267).

Tellurium, oxides of. Three oxides have been isolated, TeO , TeO_2 , and TeO_3 . TeO is probably slightly basic; TeO_2 is the anhydride of the weak acid H_2TeO_3 , but it also shows feebly basic properties; TeO_3 is a very weak acidic oxide. None of the oxides has been gasified; all are known in the solid state only. An oxide of Te and S, TeSO_3 , is also known.

TELLURIUM MONOXIDE TeO . This oxide was prepared in 1883 by Divers a. Shimósé (*C. J.* 43, 819). It is obtained by long-continued heating TeSO_3 to $180^\circ\text{--}230^\circ$ *in vacuo* until SO_2 ceases to be given off, powdering the residual solid, digesting it with water containing a little Na_2CO_3 , washing with hot water, then with alcohol, and drying in a steam oven. TeO is a black, amorphous solid, with a slight brown shade, showing a graphitic lustre when pressed with a hard body. It is unchanged in air, but when heated it burns to TeO_2 ; when strongly heated *in vacuo* TeO_2 and Te are formed. TeO is scarcely affected by cold KOHaq ; boiling KOHaq decomposes it, giving Te. SO_2 , even if boiling, scarcely acts on TeO . The oxide dissolves in hot $\text{H}_2\text{SO}_4\text{aq}$; D. a. S. say that the solution deposits $\text{Te(SO}_3)_2$ on cooling, but no analyses of the crystals that separate are given; Magnus (*P.* 10, 491) gave this formula to the product of the interaction of Te with hot conc.

H_2SO_4 . Heated in HCl gas TeCl_2 is formed. TeO is slowly reduced to Te by SO_2 .

TELLURIUM DIOXIDE TeO_2 . (*Tellurous oxide. Tellurous anhydride.*)

Occurrence.—As tellurite or tellurium ochre, in the Seven Mountains.

Formation.—1. Te is heated in the air.—2. By decomposing a boiling solution of TeCl_4 in HClaq by boiling water.—3. By heating H_2TeO_3 . 4. By oxidising Te by HNO_3aq , and heating the solution.—5. According to Hilger (*A.* 171, 211) by heating Te with H_2SO_4 , SO_2 is evolved and TeO_2 separates on cooling.

Preparation.—Powdered Te is dissolved in warm HNO_3aq , S.G. 1.25, and the solution is heated somewhat above 20° ; below 8° H_2TeO_3 separates, between 8° and 20° both TeO_2 and H_2TeO_3 are formed, and the solid that forms from the solution above 20° is TeO_2 only (Klein a. Morel, *Bl.* [2] 43, 198). By allowing the solution of Te in HNO_3aq to stand for some hours, and then adding some alcohol, TeO_2 is obtained in crystals (Oppenheim, *J. pr.* 71, 267; cf. Berzelius, *P.* 28, 392).

Properties.—A white, crystalline solid; melts at a red heat to a transparent, yellow liquid, which on cooling forms a white crystalline mass, giving off so much heat that the solid glows feebly. TeO_2 may be sublimed in a slow stream of air. Clarke (*Am. S.* [3] 14, 285) gives S.G. as 5.7559 at 12.5° . As obtained from a solution of Te in HNO_3aq , TeO_2 forms quadratic octahedra; S.G. 5.65 to 5.68 at 0° (K. a. M., *l.c.*). As obtained by heating H_2TeO_3 till all water is removed and the residue melts, TeO_2 forms orthorhombic needles; S.G. 5.88 to 5.91 at 0° (K. a. M., *l.c.*). Freshly-prepared TeO_2 has no taste, but after a time it acquires a disagreeable metallic taste (Berzelius, *P.* 28, 392). It does not redden litmus paper. It is almost insoluble in water; 1 pt. dissolves in 150,000 pts. of water (K. a. M., *l.c.*). TeO_2 is very slightly soluble in most acids; it is more soluble in HClaq (v. *infra*, *Reactions*, No. 3). Dissolves readily in solutions of caustic alkalis, but in alkali carbonate solutions and in ammonia only after long-continued boiling. TeO_2 does not form H_2TeO_3 by reacting with water, but as it is obtained by heating this acid it may be called tellurous anhydride.

Reactions and Combinations.—1. Reduced to Te by heating in hydrogen to the temperature whereat Te vaporises.—2. Easily reduced to Te by heating with carbon.—3. TeO_2 absorbs hydrogen chloride, giving off much heat and forming compounds $\text{TeO}_2 \cdot x\text{HCl}$. At -10° , after saturation with HCl , the compound $\text{TeO}_2 \cdot 3\text{HCl}$ is formed; on slightly warming HCl is given off, and $\text{TeO}_2 \cdot 2\text{HCl}$ remains, and does not change when heated to 90° ; on heating more strongly, TeOCl_2 is formed (Ditte, *A. Ch.* [5] 10, 82). Hydrogen bromide is also absorbed by TeO_2 ; by saturating TeO_2 with HBr at -15° , a black solid, resembling I, and having the composition $\text{TeO}_2 \cdot 3\text{HBr}$, is formed; this compound begins to decompose at -40° , above this temperature $\text{TeO}_2 \cdot 2\text{HBr}$ is produced, which remains unchanged to c. 800° , at which temperature it decomposes to TeOBr_2 and H_2O (D., *l.c.*). Hydrogen iodide and hydrogen fluoride are also absorbed by TeO_2 , but the products have not been ex-

aminated.—4. Tellurites (*q. v.*, p. 650) are formed by dissolving TeO_2 in caustic alkali solutions, or by fusing TeO_2 with alkali carbonates.—5. A compound of TeO_2 with sulphuric anhydride $2\text{TeO}_2 \cdot \text{SO}_3$ —sometimes called basic tellurium sulphate—is formed by dissolving TeO_2 in hot H_2SO_4 diluted with 3 to 4 times its weight of water, and evaporating; it crystallises in rhombic tablets, somewhat soluble in cold dilute H_2SO_4 (Klein, *C. R.* 99, 326).—6. A compound with nitric anhydride $2(4\text{TeO}_2 \cdot \text{N}_2\text{O}_5) \cdot 3\text{H}_2\text{O}$ is described by Klein a. Morel (*Bll.* [2] 43, 198), as obtained, in rhombic needles, by dissolving TeO_2 in moderately conc. HNO_3 , and also by dissolving Te in excess of HNO_3 , S.G. 1.15 to 1.35, and evaporating at a gentle heat. This compound—which is sometimes described as basic tellurium nitrate—is decomposed at c. 330° , giving off N oxides and leaving TeO_2 ; with much hot water it gives a pp. of TeO_2 .—7. A compound, probably $\text{TeO}_2 \cdot \text{Ag}_2\text{O} \cdot (\text{C}_2\text{H}_3\text{O}_2)_2 \cdot 2\text{aq}$, is formed by dissolving TeO_2 in HBr , adding tartaric acid, and ppg. by AgNO_3 (v. Brauner, *C. J.* 55, 398; cf. Klein a. Morel, *C. R.* 100, 1140).

TELLURIUM TRIOXIDE TeO_3 . (*Telluric oxide. Telluric anhydride.*) Obtained, as an orange-yellow, crystalline mass, by heating H_2TeO_4 (v. TELLURIC ACID, p. 649) to somewhat above 160° . If the temperature becomes too high some of the TeO_3 is decomposed to TeO_2 and O ; it is advisable, therefore, to digest the residue with cold HCl (to remove any TeO_2), to wash out HCl by water, and to dry at 100° . TeO_3 is not changed by cold, nor by boiling, water; nor is it acted on by cold HCl , by hot or cold HNO_3 , nor by dilute KOH . Very conc. boiling KOH slowly dissolves TeO_3 , forming K_2TeO_6 . TeO_3 dissolves in boiling HCl , O_2 is slowly given off, and H_2TeO_4 is formed in the solution (v. Berzelius, *P.* 28, 392). Clarke (*Am. S.* [3] 14, 286) gives S.G. of TeO_3 as 5.0704 at 14.5° .

TELLURIUM THIO-OXIDE TeSO_2 . (*Tellurium sulphoxide. Tellurium-sulphur trioxide.*) This compound is obtained by dissolving pure Te in pure SO_2 , and warming after a time to c. 30° , pouring off SO_2 , and drying *in vacuo* (Weber, *J. pr.* [2] 25, 218; for description of apparatus, and details, v. Divers a. Shimose, *C. J.* 43, 323). TeSO_2 is a red amorphous solid, melting at 30° . When pure it remains unchanged, in a sealed tube, for months (D. a. S., *l.c.*). The colour gradually changes to brown by heating to 85° ; the change is instantaneous at 90° . The product, which is a brown solid, has the composition TeSO_2 (D. a. S., *l.c.*). At c. 180° SO_2 is given off and black TeO remains (D. a. S., *l.c.*). TeSO_2 is not acted on by SO_2 ; it dissolves in H_2SO_4 , giving an amethyst-red solution; water decomposes it to H_2TeO_4 , TeO , Te , H_2SO_4 , and H_2SO_3 (D. a. S., *l.c.*).

TeSO_2 may perhaps be regarded as tellurium sulphite.

Tellurium, oxyacids of, H_2TeO_4 , v. TELLURIC ACID (p. 656); H_2TeO_5 , v. TELLURIC ACID (p. 649).

Tellurium, oxybromide of, TeOBr_2 . A pale-yellow solid; obtained by heating $\text{TeO}_2 \cdot 2\text{HBr}$ (v. TELLURIUM DIOXIDE; *Reactions*, No. 8, p. 654) above 300° . Melts at red heat, forming a very dark-coloured liquid, which gives off almost

black vapour with partial decomposition to TeO , and TeBr_4 (Ditte, *A. Ch.* [5] 10, 82).

Tellurium, oxychloride of, TeOCl_2 . Prepared by heating $\text{TeO}_2 \cdot 2\text{HCl}$ (v. TELLURIUM DIOXIDE; *Reactions*, No. 8) to above 90° . Very similar to TeOCl_2 (Ditte, *A. Ch.* [5] 10, 82). Decomposed at fairly high temperature to TeO , and TeCl_4 .

Tellurium, oxyiodide of. According to Berzelius (*Lehrbuch* [5th edit.] 3, 1141), a greyish-brown, heavy powder is formed by digesting TeI_4 with boiling water, and this powder is probably an oxyiodide of Te ; no analyses are given.

Tellurium, salts of. No compounds have been prepared by directly replacing the H of oxyacids by Te . According to Divers a. Shimose (*C. J.* 43, 319), $\text{Te}(\text{SO}_3)_2$ is formed by dissolving TeO in hot H_2SO_4 and cooling, but no analyses are given; Magnus (*P.* 10, 491) gave the formula $\text{Te}(\text{SO}_3)_2$ to the product of the interaction of Te and hot conc. H_2SO_4 . The compounds $2\text{TeO}_2 \cdot \text{SO}_3$ and $2(4\text{TeO}_2 \cdot \text{N}_2\text{O}_5) \cdot 3\text{aq}$ are sometimes called basic tellurium sulphate and basic tellurium nitrate respectively; the compound TeSO_3 (v. *supra*, TELLURIUM THIO-OXIDE) may perhaps be looked on as tellurium sulphite; and a compound, probably $\text{TeO}_2 \cdot \text{Ag}_2\text{O} \cdot (\text{C}_2\text{H}_3\text{O}_2)_2 \cdot 2\text{aq}$, is called tellurium-silver tartar emetic (v. TELLURIUM DIOXIDE; *Reactions*, Nos. 5, 6, and 7, *supra*).

Tellurium silver tartar emetic v. TELLURIUM DIOXIDE; *Reactions*, No. 7, *supra*.

Tellurium, sulphides of. Berzelius (*P.* 8, 411) described two sulphides, TeS , and TeS_2 , corresponding with the oxides TeO , and TeO_2 . According to Becker (*A.* 180, 257), CS_2 removes almost all the S from these supposed compounds. B. concludes that the substances described by Berzelius are not definite compounds; he thinks that compounds of Te and S are probably formed by passing H_2S into TeO_2 and TeO_3 . As the substances obtained by Berzelius seem to have very definite properties, they are shortly described here.

TELLURIUM DISULPHIDE TeS_2 . A dark-brown pp. formed by passing H_2S into H_2TeO_4 , or into an acidified solution of an alkali tellurite; softens when heated and cools to a grey, somewhat lustrous mass; gives off S when strongly heated. TeS_2 reacts as an acidic sulphide, forming compounds $x\text{MS} \cdot \text{TeS}_2$, where $\text{M} = (\text{NH}_4)_2$, Cd , Li , Fe , Mg , Pb , K , Na , Zn , &c. The thiotellurites of the alkali metals are best obtained by saturating aqueous solutions of the tellurites with H_2S , and crystallising *in vacuo*; the thiotellurites of alkaline earth metals are formed by boiling the sulphides of these metals with TeS_2 and water; the thiotellurites of the heavy metals are obtained by ppn. from solutions of the alkali salts (Berzelius, *P.* 8, 411).

TELLURIUM TRISULPHIDE TeS_3 . A blackish grey, lustrous solid; formed by saturating H_2TeO_4 with H_2S , and allowing to stand for some time in a closed vessel in a warm place. Thiotellurates of the alkali metals, $x\text{M} \cdot \text{TeS}_3$, are formed by saturating M_2TeO_4 with H_2S (v. Oppenheim, *J. pr.* 71, 267).

Tellurium, sulphoxide of, v. TELLURIUM THIO-OXIDE, *supra*.

Tellurium, thio-oxide of, v. *supra*.

Tellurium, thio- salts of, v. TELLURIUM DISULPHIDE, p. 655; and **TELLURIUM TRISULPHIDE**, p. 655.

M. M. P. M.

TELLUROCYANIDES v. vol. ii. p. 853.

TELLUROUS ACID H_2TeO_3 .

Formation.—1. By dissolving Te in HNO_3 Aq, S.G. 1.25, and at once ppg. by water; if the solution is left for some time before adding water the pp. is TeO_2 .—2. By decomposing TeCl_4 by cold water.

Preparation.— TeO_2 is fused with an equal weight of K_2CO_3 or Na_2CO_3 as long as CO_2 is given off; the tellurite thus formed is dissolved in water, and HNO_3 Aq is added until the liquid has a very distinctly acid reaction; the flocculent pp. thus produced is allowed to remain in contact with the liquid for some hours, and is then thoroughly shaken up with the liquid, a little HNO_3 Aq being added if the acid reaction disappears during this process; the pp. is then washed with ice-cold water, and dried at the ordinary temperature (Berzelius, *P.* 28, 392; cf. Oppenheim, *J. pr.* 71, 267). The solution of the alkali tellurite in HNO_3 Aq may be decomposed by adding water, but this must be done at once, as after standing water ppts. TeO_2 .

Properties and Reactions.—A white, light, amorphous solid, with a bitter, metallic taste. Reddens litmus paper. Dissolves slightly in cold water; when the aqueous solution is heated to c. 40° TeO_2 separates. When slightly heated gives TeO_2 and H_2O . H_2TeO_3 dissolves in many acids; from the solution in HCl Aq, water or alkalis ppts. H_2TeO_3 ; the solution in HNO_3 Aq gives a pp. of TeO_2 on addition of water after standing for some time. From the solution in H_2SO_4 Aq and HNO_3 Aq the compounds $2\text{TeO}_2 \cdot \text{SO}_3$ and $2(4\text{TeO}_2 \cdot \text{N}_2\text{O}_5) \cdot 3\text{aq}$ have been obtained (v. **TELLURIUM DIOXIDE**; **Reactions**, No. 5 and 6, p. 655). H_2TeO_3 forms **tellurites** (q. v., p. 650). Thomsen (*Th.* 2, 278) gives $[\text{TeO}_2 \cdot \text{H}^+ \text{O}] = 77,180$. M. M. P. M.

TELLURIUM, Organic Compounds of.

Methyl telluride Me_2Te . (82°). Formed by distilling K_2Te with $\text{Ba}(\text{SO}_4)_2$ (Wöhler a. Dean, *A.* 93, 233; Heeren, *Dissertation*, Göttingen, 1861). Pale-yellow, mobile, heavy oil, with persistent alliaceous smell. Oxidised by HNO_3 to $\text{Me}_2\text{TeOHNO}_2$, crystallising in prisms.— Me_2TeHOAc . Transparent cubes, v. sol. water. Its solution gives with HCl a pp. of Me_2TeCl_2 which crystallises in long prisms [97.5°].— Me_2TeBr_2 [89°]. Prisms.—(Me_2Te), H_2CO_3 . Difficult to crystallise.—Formate $\text{Me}_2\text{TeCH}_2\text{O}_2$. Deliquescent needles.— Me_2TeI_2 . Formed by heating Te with MeI at 80° (Demarcay, *Bl.* [2] 40, 100).—(Me_2Te), $\text{H}_2\text{C}_2\text{O}_4$.— Me_2TeO . Got from Me_2TeCl_2 and Ag_2O . Deliquescent crystalline mass, alkaline to litmus.— $\text{Me}_2\text{TeOCl}_2$. Got from the chloride and NH_3 Aq. Short prisms (from alcohol).—(Me_2Te), OBr_2 .—(M_2Te), H_2SO_4 . Cubes, v. sol. water, insol. alcohol.

Methyl-iodide Me_2TeI . Crystalline, sl. sol. water. Converted by moist AgCl into an alkaline base which yields (Me_2TeCl), PtCl_4 .

Ethyl telluride v. vol. ii. p. 519.

TEMLIN OIL. An essential oil obtained from fir cones (Flückiger, *J.* 1855, 642; Berthelot, *J. Ph.* [8] 29, 38). Colourless, becoming greenish-yellow in air. Boils at 155° – 177° . S.G. 1.862. Yields on rectification a levorotatory

terpene (172°) S.G. 2.856. HNO_3 ($\frac{1}{2}$ vol.) and alcohol ($\frac{1}{2}$ vol.) yield terpin hydrate $\text{C}_{10}\text{H}_{16}\text{O}_2$ aq [118°] (250°) S. 9 at 100° . Alcohol and HCl yield crystalline $\text{C}_{10}\text{H}_{16}\text{HCl}$ and $\text{C}_{10}\text{H}_{16}\text{H}_2\text{HCl}$ [55°].

TERACONIC ACID $\text{C}_4\text{H}_8\text{O}_4$, i.e.

$\text{OMe}_2\text{C}(\text{CO}_2\text{H})_2\text{CH}_2\text{CO}_2\text{H}$. **Propylidene-succinic acid**. [168°]. Formed in small quantity by distilling the isomeric terebic acid (Geisler, *A.* 208, 50). Na and NaOEt convert terebic ether into sodium ethyl teraconate (W. Roser, *B.* 15, 293). Formed also by treatment of the ether $\text{CO}_2\text{Et.CBrPr.CH}_2\text{CO}_2\text{Et}$ with alcoholic potash (Schleicher, *A.* 267, 130). Crystals, sol. alcohol and ether, v. sol. cold water. Above 163° it yields H_2O and an anhydride. Conc. HBr Aq at 0° forms terebic acid.

Salts.— BaA' .— CaA' . Pp., v. sl. sol. water.— $\text{Ag}_2\text{A}'$. Needles, m. sol. water.

Mono-ethyl ether EtHA' . Oil. Decomposes Na_2CO_3 , forming crystalline NaEtA' , a solution of which gives with AgNO_3 a pp. of the unstable AgEtA' .

Di-ethyl ether $\text{Et}_2\text{A}'$. (255 i.v.). Oil.

TERACRYLIC ACID $\text{C}_4\text{H}_6\text{O}_2$. (218° i.v.). A product of the distillation of terpenylic acid (Fittig a. Krafft, *B.* 10, 521, 1659, 1740; *A.* 208, 79; Amthor, *J. pr.* [2] 42, 389). Liquid, smelling like valeric acid, sl. sol. and lighter than water. Yields acetic acid on fusion with potash. Fuming HBr forms $\text{C}_4\text{H}_5\text{BrO}_2$, which gradually splits up into HBr and heptolactone $\text{C}_7\text{H}_{12}\text{O}_2$.— CaA' , 5aq. Prisms or needles.— AgA' .—needles.

Ethyl ether EtA' . (191°). Fruity oil.

TERBIUM. Tr. At. w. not determined with certainty; probably c. 162 (v. *infra*).

The examination of *gadolinite*, a rare Swedish mineral, by Mosander, Cleve, and others made probable the existence therein of at least seven earths, to one of which the name terbia was given (v. **ERBURIUM**, vol. ii. p. 456, where the history of these earths is stated more fully, with references to original memoirs). It is still very doubtful whether the substance called terbia is a homogeneous body or a mixture of more than one compound (cf. **METALS**, **RARE**, vol. iii. p. 242). Delafontaine (*A. Ch.* [5] 14, 238) prepared an orange-yellow, earthy compound, which he regarded as pure terbia, from *samaraskite*, by a long process of fractional ppg., first by K_2SO_4 Aq, then by oxalic acid, and finally by formic acid (cf. Marignac, *A. Ch.* [5] 14, 247; Cleve, *Bl.* [2] 81, 197).

Terbia Tr_2O_3 is described as an orange-yellow amorphous solid; when heated in H for some time it becomes white. Tr_2O_3 dissolves in acids, forming salts of the type Tr_2X_3 , where $\text{X} = \text{SO}_3$, CO_3 , 2NO_3 , &c. The emission spectrum of terbia has been mapped by Roscoe a. Schuster (*C. J.* 41, 283). The at. w. of Tr—the supposed element has not been isolated—was determined by Delafontaine to be 113.5; Marignac found the value 148.5; Lecoq de Boisbaudran found 163.1, 161.4, and by later work 159.5 (*C. R.* 102, 395; 111, 474). M. M. P. M.

TEREBENE v. TERPENES.

TEREBENTHENE v. TERPENES.

DITERBENTHYL $\text{C}_{20}\text{H}_{30}$. V.D. 4.6. (845°). S.G. 1.29688. $[\alpha]_D^{20} = 59^\circ$. A product of distillation of colophony (Renard, *C. R.* 105, 865; 106, 856). Oil, resinified by air. KMnO_4 oxidises it

to propionic, acetic, and formic acids and CO_2 . Cold fuming HNO_3 forms $\text{C}_{10}\text{H}_{12}(\text{NO}_2)_2$, a yellow powder, sol. alcohol and ether. Br in CS_2 at -10° forms $\text{C}_{10}\text{H}_{12}\text{Br}_2$, which on heating yields diterebenthylene $\text{C}_{10}\text{H}_{12}$ (347°) S.G. 1.2 9821, whence Br forms $\text{C}_{10}\text{H}_8\text{Br}_4$. HNO_3 produces $\text{C}_{10}\text{H}_{12}(\text{NO}_2)_2$, and H_2SO_4 forms $\text{C}_{10}\text{H}_{12}\text{SO}_4\text{H}$, all amorphous solids. Bromine-water gives rise to $\text{C}_{10}\text{H}_2\text{Br}_8$, a brown, amorphous solid. Gaseous HCl passed into the ethereal solution forms $\text{C}_{10}\text{H}_{10}\text{Cl}_2$. H_2SO_4 yields $\text{C}_{10}\text{H}_{12}\text{SO}_4\text{H}$, which is sol. water, alcohol, and ether, forming fluorescent solutions. Diterebenthyl passed through a red-hot tube forms H , C_2H_4 , C_2H_2 , pentane, hexane, hexylene, hexene, heptene, cymene, and other hydrocarbons.

TEREBENTILIC ACID $\text{C}_{10}\text{H}_{16}\text{O}_2$. [90°]. (250°). Got by passing the vapour of the hydrate of oil of turpentine $\text{C}_{10}\text{H}_{16} \cdot 2\text{H}_2\text{O}$ over soda-lime at 400° (Personne, A. 100, 253; cf. Hempel, A. 180, 86). Crystalline powder, sol. hot water, v. sol. alcohol and ether. May be sublimed.— AgA' . Crystalline.

TEREBENTIC ACID $\text{C}_{10}\text{H}_{14}\text{O}_2$. Got by digesting oil of turpentine with oxide of lead (Weppen, A. 41, 294). Crystals (from alcohol).

TEREBIC ACID $\text{C}_{10}\text{H}_{10}\text{O}_4$, i.e.

$\text{CMe}_2 \left\langle \begin{array}{c} \text{CH}(\text{CO}_2\text{H}) \\ \text{O} \end{array} \right\rangle \text{CH}_2$. Mol. w. 158. [176°].

H.C.v. 766, 642 (Ossipoff, C. R. 108, 812). S. (ether) 2.856 at 85° (Amthor, J. pr. [2] 42, 385). Formed by the action of nitric acid on oil of turpentine (Bromeis, A. 37, 297; Rabourdin, J. Ph. [3] 6, 185; Cailliot, A. Ch. [3] 21, 27; Svanberg, A. Eckmann, J. pr. 66, 220; Mielck, A. 180, 47; Bredt, A. 208, 37; Erdmann, A. 228, 179). Formed also by oxidising pinol (Wallach, A. 253, 256; 259, 317). Terebic acid is perhaps identical with oxyhexic acid (Gorboff, J. R. 1887, 605). Monoclinic crystals (from alcohol), sl. sol. cold, v. sol. hot water. V. sol. alcohol and ether. Not attacked by fuming HNO_3 . Split up by water at 150° into CO_2 and pyroterebic acid. On boiling with H_2SO_4 (2 pts.) and water (1 pt.) it is converted into the lactone of oxy-isohexoxic acid $\text{CMe}_2 \left\langle \begin{array}{c} \text{CH}_2 \\ \text{O} \end{array} \right\rangle \text{CH}_2$, CO_2 being evolved. On distillation it yields pyroterebic (hexenoic) acid, oxy-isohexoxic lactone, and a little tereconic acid. On heating for 15 hours at 160° with excess of a saturated solution of baryta it is converted into acetone and succinic acid (Frost, A. 226, 863). Fuming HNO_3 yields $\text{CH}_3\text{Pr} \cdot \text{CH}_2 \cdot \text{CO}_2\text{H}$. Alkalis form salts of diaterebic acid, of which terebic acid is the lactone.

Salts.— $\text{NH}_4\text{A}'$: very soluble prisms.— $\text{KA}' \frac{1}{2}\text{aq.}$ — $\text{NaA}' \frac{1}{2}\text{aq.}$ — $\text{BaA}' \frac{1}{2}\text{aq.}$: amorphous.— AgA' . Prisms, v. sol. water.

Ethyl ether EtA'. (274° i.v.). S.G. 1.111. Formed from terebic acid, alcohol, and HCl . Dilute NaOH dissolves it, forming monoethyl diaterebate; on cautious acidification the ether separates again, but only after warming (Ekmann). Sodium dissolves in its ethereal solution, giving off hydrogen and forming the sodium salt of acid ether of tereconic acid (g.v.). Alcoholic NaOEt acts in the same way, excess forming a white pp. of disodic tereconate.

Diaterebic acid

$\text{CMe}_2(\text{OH})\text{CH}(\text{CO}_2\text{H})\text{CH}_2\text{CO}_2\text{H}$. The salt BaA'' 8aq is formed by boiling terebic acid with excess of baryta-water. It crystallises from

Vol. IV.

alcohol, but on acidification at once yields the lactone, terebic acid. AgNO_3 added to a solution of the Ba salt ppts. AgA'' .— CaA'' 8aq.— CaA'' .— PbA'' 8aq.— $\text{PbA}'' \frac{1}{2}(\text{OH})_2$ aq.

Ethyl ether EtA'. Formed from AgA'' and EtI. Oil. Converted by acetyl chloride into $\text{CMe}_2(\text{OAc})\text{CH}(\text{CO}_2\text{Et})\text{CH}_2\text{CO}_2\text{Et}$, an unstable oil.

β -Bromo-terebic acid $\text{C}_8\text{H}_8\text{BrO}_4$, i.e.

$\text{CMe}_2 \left\langle \begin{array}{c} \text{CBr}(\text{CO}_2\text{H}) \\ \text{O} \end{array} \right\rangle \text{CH}_2$. [151°]. Formed by adding Br (1 mol.) to powdered tereconic acid (1 mol.) covered with water (Frost, A. 226, 863). Large crystals, m. sol. CS_2 , v. sl. sol. chloroform and benzene. Decomposed by boiling with water into HBr and terebilioic acid $\text{C}_8\text{H}_8\text{O}_4$. Reduced by sodium-amalgam to terebic acid.

References.—CHLORO- and OXY-TEREBIC ACID.

TEREBILENIC ACID $\text{C}_8\text{H}_8\text{O}_4$, i.e.

$\text{CMe}_2 \left\langle \begin{array}{c} \text{C}(\text{CO}_2\text{H}) \\ \text{O} \end{array} \right\rangle \text{CH}$ (?) [169°]. Formed by

heating α -chloro-terebic acid at 200° (Roser, B. 15, 296; A. 220, 261) and by evaporating β -chloro-terebic acid with water (Frost, A. 226, 870). Small prisms or needles (from water), v. sol. alcohol and ether. Crystallises from alcohol or conc. HBrAq in trimetric forms; $a:b:c = 809:1:858$. May be sublimed. Excess of KOH forms the diaterebilenate $\text{K}_2\text{C}_8\text{H}_8\text{O}_4$, but this splits up on warming with water into KOH and potassium terebilenate. Does not combine with Br or HBr . Sodium-amalgam reduces it to terebic acid.— CaA'_2 .— AgA' . Prisms.

Reference.—CHLORO-TEREBILENIC ACID.

TERECHRYSIC ACID $\text{C}_8\text{H}_8\text{O}_4$. A product of the action of HNO_3 (S.G. 1.2) on turpentine (Cailliot, A. 64, 376). Orange-red crystals, v. e. sol. water, alcohol, and ether.— PbA' : crystals.

TERELACTONE $\text{C}_8\text{H}_8\text{O}_4$, i.e. $\text{C}_8\text{H}_8 \left\langle \begin{array}{c} \text{O} \\ \text{CO} \end{array} \right\rangle$ [127°.

(210° i.v.). Formed by the action of boiling water on di-bromo-isohexoxic acid derived from pyroterebic acid and Br (Geisler, A. 208, 47). Mobile liquid, sol. water. Boiling baryta-water converts it into amorphous $\text{Ba}(\text{C}_8\text{H}_8\text{O}_4)_2$, which is sol. water and deposits BaCO_3 on boiling.

TEREPHTHALIC ACID $\text{C}_8\text{H}_6\text{O}_4$, i.e. $\text{C}_6\text{H}_4(\text{CO}_2\text{H})_2$, *p*-Phthalic acid. Mol. w. 166. H.C.p. 770,900. H.C.v. 771,200. H.F. 188,100 (Stohmann, J. pr. [2] 40, 139).

Formation.—1. By the action of HNO_3 on oil of turpentine (Cailliot, A. Ch. [3] 21, 28; De la Rue, A. Hugo Müller, A. 121, 86; Schreder, B. 7, 704; cf. W. C. Williams, B. 6, 1094).—2. By the oxidising action of chromic acid mixture on *p*-xylene (Beilstein, A. 133, 32; 137, 301), cuminic acid, cuminic aldehyde, cymene (Hofmann, A. 97, 197), *p*-toluic acid (Beilstein, A. 137, 308), di-ethyl-benzene, and amyl-toluene (Fikig, A. 141, 167).—3. By the action of boiling dilute HNO_3 on cymene and on terpenes (Schwanert, A. 132, 257; Homeyer, A. Ph. [3] 5, 326).—4. By oxidation of *o*-ethyl-toluene by aqueous KMnO_4 (Claus, A. Pieszcok, B. 19, 3083).—5. By fusing potassium *p*-sulphobenzoate with sodium formate (Remsen, B. 5, 379).—6. From its nitrile, which is obtained by distilling K_2FeCy_4 with potassium benzene *p*-disulphonate (Garrick, Z. 1869, 551), *p*-chlorobenzene sulphonate (Nölting, B. 8, 1113), or *p*-

U U

bromo-benzene sulphonate (Ireland, Z. 1869, 164; Barth a. Senhofer, A. 174, 242; Limpricht, A. 180, 88).—7. The semi-nitrile is also formed by the action of a hot solution of cuprous potassium cyanide upon *p*-diazobenzoic acid (Sandmeyer, B. 18, 1497).—8. By heating *p*-di-bromo-benzene with chloroformic ether and 1 p.c. sodium-amalgam at 110° and saponifying the product (Bonz, B. 18, 2305).—9. By the action of 5 p.c. KMnO₄ on an oil (258°–263°) which remains as a residue in the manufacture of aniline and toluidine (Hell a. Rockenbach, B. 22, 505).

Preparation.—1. Br (2 mols.) is added to boiling *p*-xylene (100 g.), and the resulting C₆H₄(CH₂Br)₂ decomposed by alcoholic KOAc on the water-bath. After evaporating the alcohol the C₆H₄(OAc)₂ is extracted with ether, and oxidised by adding 4.5 litres of 10 p.c. KMnO₄ to its solution in water (1 litre) and NaOH (500 g. of S.G. 1.22). Finally more KMnO₄ is added till the solution remains violet, the solution kept at 100° for 3 hours, filtered, and ppd. by HCl (Baeyer, A. 245, 139).—2. By oxidising *p*-xylene with chromic acid mixture (Beilstein, A. 133, 41). 3. From *p*-toluidine by Sandmeyer's reaction, the resulting *p*-toluic acid being oxidised by KMnO₄ (Baeyer a. Herb, A. 258, 1).

Properties.—White crystalline powder, nearly insol. water, alcohol, ether, chloroform, and HOAc. Sublimes without previous fusion. Does not yield an anilide on boiling with aniline (Michael a. Palmer, B. 19, 1376). It is ppd. from its salts by phthalic acid. Yields benzene when distilled with slaked lime. Reduced by sodium-amalgam in a current of CO₂ to the Δ^{2,4} or (1,4)-dihydride. If CO₂ be not used the product is the Δ^{1,4} or (3,6)-dihydride, which is also got by boiling the (1,4)-dihydride with NaOHAq (Baeyer, A. 269, 153; cf. Mohs, Z. [2] 3, 68). The (1,4)-dihydride gives benzoic acid on oxidation by MnO₂ and dilute H₂SO₄, while the (3,6)-dihydride forms terephthalic acid (Baeyer, A. 269, 182). By heating its alkaline solution with sodium-amalgam terephthalic acid is reduced to a tetrahydride, and this is further reduced by HIAq at 240° to a hexahydride (Baeyer, B. 19, 1805).

Salts.—(NH₄)₂A". Small crystals. —CaA" 3aq. S. 0.8 at 6°. —BaA" 4aq. S. 2.8 at 5°. —SrA". S. 1.9 at 17°. —Ag₂A". Curdy pp.

Mono-methyl ether MeHA". [c. 230°]. Formed by the action of conc. H₂SO₄ or alcoholic potash on the di-methyl ether (Baeyer, A. 245, 141). Needles, sol. Na₂CO₃Aq and hot water.

Di-methyl ether Me₂A". [140°]. S. 3 at 100°. H.F. 172,800 (Stohmann, J. pr. [2] 43, 2). Formed by heating the acid with PCl₅ on the water-bath and pouring the product into methyl alcohol. Trimetric plates; *a:b:c* = .843:1.3:0.83. Insol. cold water, sl. sol. hot MeOH, m. sol. EtOH.

Di-ethyl ether Et₂A". [44°]. Prisms.

Propyl ether Pr₂A". [81°]. Needles.

Isopropyl ether Pr₂A". [56°]. Plates.

***n*-Butyl ether (C₄H₉)₂A".** Liquid.

Isobutyl ether (CH₃Pr)₂A". [52–5°]. Needles, v. sol. ether (Berger, B. 10, 1742).

Isoamyl ether (C₅H₁₁)₂A". Pearly scales.

Phenyl ether PhA". [194°] (Baeyer, A. 258, 44). Formed from the chloride and phenol. Leaflets.

Chloride C₆H₄(COCl)₂. [78°]. (259°).

Amic acid C₆H₄(CONH₂)₂.CO₂H. [214°]. Formed from *p*-diazobenzoic acid by Sandmeyer's reaction (Sandmeyer, B. 18, 1498). Minute plates (from water), m. sol. cold water.

Amide C₆H₄(CONH₂)₂. Formed from the chloride and NH₃Aq. Amorphous.

Nitrile C₆H₄(CN)₂. [220°] (Luckenbach, B. 17, 1428). Formed from the amide and P₂O₅. Got also by distilling calcium bromo-benzene *p*-sulphonate with K₂FeCy₆. Conc. HIAq forms C₆H₄(Cl₂NH₂)₂ (Biltz, B. 25, 2543).

***Γ* cistrans Δ^{3,5} or (1,4)-Dihydride**

CO₂H.CH< $\begin{smallmatrix} \text{CH:CH} \\ \text{CH:CH} \end{smallmatrix}$ >CH.CO₂H. S. .3 in the

cold. H.F. 182,600 (Stohmann, J. pr. [2] 43, 538). Formed by reducing terephthalic acid in a current of CO₂ by sodium-amalgam (Baeyer, A. 251, 257; 269, 153). Monoclinic prisms (from EtOAc); *a:b:c* = .982:1.1:0.19; β = 78° 2'. M. sol. ether. Not attacked by sodium-amalgam in the cold. Unites with bromine (4 atoms). Transformed into the Δ^{1,5} isomeride by boiling with water, and into the Δ^{1,4} acid by boiling with NaOHAq. Alkaline KMnO₄ re-oxidises the acid to terephthalic acid. A warm solution of the acid readily reduces AgNO₃. On warming with aqueous cupric acetate it gives off CO₂ and forms a white pp. which, on adding HOAc and warming, yields Cu₂O, the liquid then containing benzoic acid. The (3,6), (3,4), and (2,3) isomerides do not reduce AgNO₃ and cupric acetate. The Ba salt crystallises in plates, and is v. sol. water.

Methyl ether Me₂A". [77°]. Yields a di- and a tetra-bromide. Br in CHCl₃ forms a dibromide [170°] and a tetrabromide [98°].

Di-phenyl ether Ph₂A". [146°]. Formed from the chloride and phenol at 100°. Small crystals, sl. sol. alcohol, ether, and ligroin.

***Γ* cis Δ^{3,5} or (1,4)-Dihydride**

CO₂H.CH< $\begin{smallmatrix} \text{CH:CH} \\ \text{CH:CH} \end{smallmatrix}$ >C(CO₂H)H. Extracted by

ether from the mother-liquor from which the preceding isomeride has separated. Closely resembles its *cistrans* isomeride, but the *cis* acid and its salts are the more soluble.

Δ^{1,5} or (3,4)-Dihydride

CO₂H.CH< $\begin{smallmatrix} \text{CH:CH} \\ \text{CH}_2\text{CH}_2 \end{smallmatrix}$ >C.CO₂H. S. .042 in the

cold. H.F. 185,300. Formed by boiling the (1,4)-dihydride with water, and obtained, therefore, by reducing terephthalic acid with sodium-amalgam (Baeyer, A. 245, 142; 251, 257; 269, 148). Converted into the (3,6)-acid by NaOHAq. Sodium-amalgam in the cold reduces it to the Δ² tetrahydride.—BaA" 4aq. Trimetric crystals; *a:b:c* = .319:1.:352 (Baeyer a. Herb, A. 258, 22).

Methyl ether Me₂A". [40°].

Δ^{1,4} or (3,6)-Dihydride

CO₂H.C< $\begin{smallmatrix} \text{CH}_2\text{CH} \\ \text{CH}_2\text{CH}_2 \end{smallmatrix}$ >C.CO₂H. S. .0059 in the

cold. H.F. 191,900. Formed by reduction of terephthalic acid in alkaline solution by sodium-amalgam (Baeyer, A. 245, 142). Got also by boiling the (1,4)-dihydride with NaOHAq. Slender needles (from water), almost insol. ether. Much resembles terephthalic acid. On sublimation it is partially converted into terephthalic

acid. Immediately oxidised by KMnO_4 . Forms $\text{CH}(\text{CO}_2\text{H})\langle\text{CH}_2\text{CHBr}\rangle\text{CH}_2\text{CO}_2\text{H}$ by uniting with HBr . Sodium-amalgam in the cold reduces it to a slight extent, forming the two isomeric Δ^2 tetrahydrides.— BaA'' 4aq. Crystals, resembling its $\Delta^{1,5}$ and $\Delta^{1,8}$ isomerides.

Mono-methyl ether MeA''. [225°]. Got from $\text{Me}_2\text{A}''$ and alcoholic potash. Needles (from hot water).

Di-methyl ether Me₂A''. [180°]. H.F. 172,700. Formed from the dihydride by successive treatment with PCl_5 (2 mols.) and MeOH . Monoclinic plates (from EtOAc); $a:b:c = 1.52:1.2:79$; $\beta = c. 74^\circ$. Sl. sol. water, m. sol. hot alcohol, v. e. sol. ether. Br in CHCl_3 yields a dibromide $\text{C}_6\text{H}_2\text{Br}_2(\text{CO}_2\text{Me})_2$ [90°] and a tetrabromide [150°]. Excess of Br yields $\text{CO}_2\text{Me.C}_6\text{H}_2\text{Br}\langle\text{CO}\rangle$ [188°]. HBr forms $\text{C}_6\text{H}_2\text{Br}_2(\text{CO}_2\text{H})_2$ which yields $\text{C}_6\text{H}_2\text{Br}_2(\text{CO}_2\text{Me})_2$ [166°].

Di-phenyl ether Ph₂A''. [191°]. Formed by treating the chloride with phenol (Baeyer a. Herb. A. 258, 31). Small scales (from hot MeOH), sl. sol. ether.

$\Delta^{1,8}$ or (5,6)-Dihydride

$\text{CO}_2\text{H.C}\langle\text{CH}_2\text{CH}_2\rangle\text{C.CO}_2\text{H}$. S. 0053 in the cold. Formed by the action of alcoholic potash on the dibromide of the Δ^2 tetrahydride and on the tetrahydride of di-bromo-terephthalic acid got by bromination of the hexahydride. Unites with hydrogen bromide (2 mols.) forming $\text{CO}_2\text{H.C}\langle\text{CH}_2\text{CH}_2\rangle\text{CH.CO}_2\text{H}$. Easily reduced by Zn and HOAc and by sodium-amalgam to the two Δ^2 tetrahydrides. Boiling water converts it into the (3,4)-isomeride. Boiling NaOHAq forms the (3,6)-isomeride.— BaA'' 4aq. Needles (from hot water).

Methyl ether MeA''. [85°]. Monoclinic plates; $a:b:c = 2.241:1.3:591$; $\beta = 87^\circ 13'$. Slowly converted by HBr into (2,3)-di-bromo-terephthalic acid hexahydride, which is reduced by zinc-dust and acetic acid to the Δ^2 tetrahydride of terephthalic acid. Yields a dibromide [64°].

Di-phenyl ether Ph₂A''. [175°]. Large needles (from MeOH), sl. sol. cold alcohol.

Δ^1 or (3,4,5,6)-Tetrahydride.

$\text{CH}(\text{CO}_2\text{H})\langle\text{CH}_2\text{CH}_2\rangle\text{C.CO}_2\text{H}$. [above 300°]. S. 102 at 16°; 83 at 100°. H.F. 214,200 (Stohmann, J. pr. [2] 43, 5). Formed by boiling a solution of terephthalic acid (1 pt.) in NaOHAq for twenty hours with gradual addition of 4 p.c. sodium-amalgam (100 pts.) (Baeyer, B. 19, 1805; A. 245, 160; 258, 32). Prisms, more sol. water than terephthalic acid or its dihydrides. Combines with HBr and with Br (1 mol.). Immediately reduces alkaline KMnO_4 , yielding oxalic acid.— BaA'' 3½aq. M. sol. cold water. Reduced by HIAq at 240° to the hexahydride.— $\text{Ag}_2\text{A}''$. Amorphous.

Methyl ether MeA''. [89°]. H.F. 196,200. Plates. Its ethereal solution shows blue fluorescence and gives a fugitive rose-red pp. with NaOEt . HBr gives $\text{C}_6\text{H}_2\text{Br}(\text{CO}_2\text{H})_2$, whence MeA'' [95°]. Bromine forms $\text{C}_6\text{H}_2\text{Br}_2(\text{CO}_2\text{Me})_2$ [81°].

Di-phenyl ether Ph₂A''. [145°]. Formed

from the acid by successive treatment with PCl_5 and phenol. Monoclinic crystals; $a:b:c = 2.824:1.2:470$, m. sol. cold alcohol and ether.

Γ *cis*trans Δ^2 or (1,4,5,6)-Tetrahydride

$\text{CH}(\text{CO}_2\text{H})\langle\text{CH}_2\text{CH}_2\rangle\text{CH.CO}_2\text{H}$. [c. 220°].

S. 17. Formed by reducing $\Delta^{1,8}$ dihydride and also the dibromide of the $\Delta^{1,8}$ dihydride. Oxidised by KMnO_4 in the cold to succinic acid and a soluble acid [150°]. Alkaline K_2FeCy_4 gives terephthalic acid. Yields three dibromides

$\text{CH}(\text{CO}_2\text{H})\langle\text{CH}_2\text{CH}_2\rangle\text{CH.CO}_2\text{H}$. [171°],

[51°], and [94°]. The Ba and Cd salts are more sol. water than those of the Δ^1 isomeride.

Methyl ether Me₂A''. [c. 8°].

Amide. Dimetric needles; $a:c = 1:2:151$.

Diphenyl ether Ph₂A''. Formed, in two modifications [107°] and [c. 190°] by the successive action of PCl_5 and phenol (Baeyer a. Herb. A. 258, 39). The modification [c. 190°] probably is a mixture containing the Δ^1 isomeride.

Dibenzyl ether (C₆H₅)₂A''. [48°]. From $\text{Ag}_2\text{A}''$ and benzyl chloride.

Γ *cis* Δ^2 or (1,4,5,6)-Tetrahydride. [150°–155°]. S. 27 in the cold. Formed, together with the *cis*trans isomeride, by reducing the $\Delta^{1,4}$ dihydride by sodium-amalgam in the cold. The Ba, Cd, and Ag salts are amorphous. This acid and the *cis*trans isomeride are converted into the Δ^1 isomeride by boiling with NaOHAq .

Γ *cis*trans Hexahydride

$\text{CO}_2\text{H.C}\langle\text{CH}_2\text{CH}_2\rangle\text{CH.CO}_2\text{H}$. *Fumaroid or*

stable modification. [300°]. S. 086 at 16°; 1.3 at 100°. H.F. 236,500 (Stohmann, J. pr. [2] 43, 7). Formed by heating the tetrahydride with HIAq for 6 hours at about 240° (Baeyer, B. 19, 1806; 245, 170; 251, 257). Formed also by heating ethyl butane tetracarboxylate with NaOEt and ethylene bromide at 100°; the product being hydrolysed and heated at 220° till evolution of CO_2 ceases (Mackenzie a. Perkin, jun., C. J. 61, 174). Prepared by reducing the hexahydride of bromo-terephthalic acid with zinc-dust and HOAc . Small prisms, sol. hot water. May be sublimed. Not oxidised by cold alkaline KMnO_4 . Br (2 mols. at 100°) forms $\text{C}_6\text{H}_2\text{Br}(\text{CO}_2\text{H})_2$ [71°], and a maleic isomeride [205°]. Treatment with PCl_5 followed by Br at 150° forms $\text{C}_6\text{H}_2\text{Br}_2(\text{CO}_2\text{H})_2$ in a fumaroid modification which yields MeA'' [150°] and a maleic modification which yields $\text{Me}_2\text{A}''$ [68°] and an anilide [200°]. The K and Ba salts are v. sol. water; the Ca salt is sl. sol. water.

Methyl ether MeA''. [71°]. S. 5 at 100°. H.F. 218,100. Exhibits no fluorescence. Volatile with steam.

Diphenyl ether Ph₂A''. [151°]. Needles.

Γ *cis* Hexahydride

$\text{CO}_2\text{H.C}\langle\text{CH}_2\text{CH}_2\rangle\text{C}(\text{CO}_2\text{H})\text{H}$. *Maleic or*

labile modification. [182°]. H.F. 237,400. Formed by reducing the very soluble hexahydride of bromo-terephthalic acid with zinc-dust and HOAc . Plates (from water), v. sol. alcohol and ether. Changes on heating with HClAq at 180° into its isomeride. Its Ba salt and methyl ether do not crystallise.

References.—BROMO-, CHLORO-, NITRO-, and OXY- TEREPHTHALIC ACID.

TEREPHTHALIC ALDEHYDE

$C_8H_6(CHO)_2$, [1:4]. [116°]. (247°). S. 1·7 at 100°. Formed by boiling $C_8H_4(OH)_2$ or $C_8H_4(OH)_2Br_2$ (1 pt.) with lead nitrate (1 pt.) and water (20 pts.) (Grimaux, *C. R.* 83, 825; Löw, *A.* 231, 363). Formed also by the action of fuming HNO_3 on di-*o*-bromo-*p*-xylene (Löw, *B.* 18, 2072), and by boiling $C_8H_4(OH)_2$ with water (Colson a. Gautier, *Bl.* [2] 45, 6, 508). Obtained from $CH_2(OH).C_6H_4.CH_2OEt$ by successive treatment with PCl_5 and water (Colson, *Bl.* [2] 42, 152).

Preparation.—*p*-Xylene (1 pt.) is heated with Br (6 pts.) at 140° to 200° with inverted condenser. The crystalline tetra-*o*-bromo-xylene [169°] thus obtained is heated with three times its weight of H_2SO_4 (S.G. 1·825 at 120°–180°), the product poured into water, and the needles that separate recrystallised from water (Hönig, *M.* 9, 1153).

Properties.—Long needles, v. sl. sol. hot water and cold ether, v. sol. alcohol. Slightly volatile with steam. Dissolves in 25 pts. of saturated aqueous $NaHSO_4$ at 45°.

Reactions.—1. Oxidised by chromic acid mixture to *p*-aldehyde-benzoic acid and then to terephthalic acid.—2. Conc. $NaOHAq$ forms terephthalic acid, *o*-oxy-toluic acid, and di-*o*-oxy-xylene.—3. KNO_3 and excess of H_2SO_4 at 110° form nitro-terephthalic aldehyde.—4. Cold conc. NH_3Aq forms tri-*p*-aldehyde-hydrobenzamide ($C_8H_4(CHO).CH.N_2$), a crystalline powder, insol. water, alcohol, and ether, yielding on oxidation by $KMnO_4$ crystalline $N_2(CH_2C_6H_4CO_2H)_2$ (Oppenheimer, *B.* 19, 574).—5. Dry or alcoholic NH_3 forms crystalline $C_8H_4(CH:NH)_2$.—6. $NaOAc$ and Ac_2O give *p*-aldehyde-cinnamic acid.—7. Acetone and dilute $NaOH$ give a white pp. of $C_8H_4(CH:CH.CO.CH_3)_2$, which crystallises from ether-acetone in matted needles [156°], insol. water and alcohol, and gives a deep-red solution in conc. H_2SO_4 . An intermediate body is $C_8H_4(CH(OH).CH.CO.C_6H_4)_2$.—8. $NPhMe_2$ and $ZnCl_2$ form $C_8H_4(CHO).CH(C_6H_5.NMe_2)_2$, the leuco derivative of the aldehyde of malachite green.—9. Cold conc. aqueous KC_2O_4 added to a cold saturated alcoholic solution of the aldehyde ppts. amorphous $C_{12}H_8O_4$, which probably has the formula $C_6H_4(CHO).CH(OH).CO.C_6H_4(CHO)$ [170°–174°]. This body reduces cold ammoniacal $AgNO_3$, forming a mirror. It also reduces warm Fehling's solution and combines with phenyl-hydrazine. $KMnO_4$ oxidises it to benzoïn di-*p*-carboxylic acid. $NaOHAq$ dissolves it, forming benzoïn di-*p*-carboxylic acid, di-*o*-oxy-*p*-xylene, and other bodies (Oppenheimer, *B.* 19, 1814).

Phenyl-hydrazide [230°].

Oxim $C_8H_4(CH:NOH)_2$. [200°]. Formed from the aldehyde and an alkaline solution of hydroxylamine (Westenberger, *B.* 16, 2994). Crystalline, v. sol. alcohol and ether, sl. sol. water. Yields $C_8H_4(CH:NOEt)_2$ [55°] and $C_8H_4(CH:NOAc)_2$ [155°].

Reference.—NITRO-TEREPHTHALIC ALDEHYDE.

TEREPHTHALIC AMIDINE $C_8H_4N_2$, *i.e.* $C_8H_4(C(NH).NH_2)_2$. The salt B^+2HCl^- , formed by digesting terephthalic imido-ethyl ether with alcoholic NH_3 , is crystalline, and yields $B^+H.PtCl_6^-$ (Luckenbach, *B.* 17, 1436).

TEREPHTHALOPHENONE *v.* PHTHALOPHENONE.

TERPENES $C_{10}H_{16}$; also Sesquiterpenes $C_{15}H_{24}$, and Polyterpenes $(C_{10}H_{16})_n$. The greater number of these hydrocarbons exist ready formed as constituents of essential oils secreted by plants. Others are produced from the natural terpenes by the action of heat or of chemical agents. A dihydrocymene isomeric with the natural terpenes has been obtained synthetically from methyl-isopropyl succino-succinic ester and the homologous dihydroparaxylene and dihydrobenzene by corresponding processes (Baeyer, *B.* 25, 1840, 2122; 26, 232). The natural terpenes are generally optically active liquids, with right- or left-handed rotatory power. The only exception is the racemic compound dipentene (*q. v.*). The following isomerides are known:—

i. **Pinene**. This includes two varieties, australene or dextropinene and terebenthene or lævopinene. American spirit of turpentine consists chiefly of dextropinene. [156°]. $[\alpha]_D^{25} = +21\cdot5$ (Berthelot, *A.* 83, 105; 88, 345, 110, 367, *Suppl.* ii. 226). S.G. $\frac{4}{4} = \cdot8765$; $\frac{25}{25} = \cdot8586$; $\frac{100}{100} = \cdot8278$ (Tilden, *unpubl. expts.*). French turpentine oil consists almost wholly of lævopinene. (156·5°). $[\alpha]_D^{25} = -40\cdot32$. S.G. $\frac{4}{4} = \cdot8767$; $\frac{17\cdot88}{17\cdot88} = \cdot8619$ (Riban, *C. R.* 78, 786; 79, 314). It is also present in oil of rosemary (Brylants, *J.* 1879, 944), oil of lemon (Tilden, *Ph.* [3] 9, 654), sage and juniper (*C. J.* 31, 554), thyme and anise (Brühl, *B.* 21, 156), and other essential oils.

For production and properties of turpentine oils *v.* OILS, ESSENTIAL, Thorpe's DICTIONARY OF APPLIED CHEMISTRY.

Different specimens of the pinenes, both dextro- and lævo-, obtained by fractional distillation from turpentine exhibit considerable variations in their rotatory power. An optically inactive liquid has been obtained by Wallach (*A.* 258, 343) from pinene nitroschloride by treatment with aniline, whereby a diazo-compound is formed, which with the neighbouring chlorine atom gives rise to diazobenzenechloride and regenerates the hydrocarbon

$-CCl-C.NO- + H_2NC_6H_5$
 $= -CCl-C(N:NC_6H_5)- + H_2O$ and
 $-CCl-C(N:NC_6H_5)- = -C=C- + ClN.C_6H_5$.
 The hydrocarbon thus obtained boils at 155°–156°, has a density ·858 at 20°, a refractive index for D 1·46553 at 21°, and is supposed to be identical in constitution with the pinenes. It is apparently not resolvable into a mixture of dextro- and lævo-pinenes, but with nitrosyl chloride and other reagents it behaves in the same manner as pinene.

Dry pinene unites with one molecule of dry hydrogen chloride, forming a crystalline compound formerly called artificial camphor [125°], which appears quite saturated, as it is unacted upon either by excess of hydrogen chloride or bromine. The hydrochloride prepared from dextropinene is dextrorotatory, while that from lævopinene is lævorotatory. The compound is very stable; it may be distilled almost without change, mere traces of hydrogen chloride being evolved; and it is unacted upon by aqueous solutions of the alkalis, except at high temperatures under pressure. Heated with sodium stearate, benzoate, or acetate, or with alcoholic potash, it loses the elements of hydrogen chloride and yields solid camphene (*v.* CAMPHENE, *infra*). In the presence

of water, alcohol, ether, or acetic acid, pinene takes up two mols. of hydrogen chloride, producing a compound of different character [50°], which on the application of heat is readily split up into hydrogen chloride and a mixture of liquid hydrocarbons (*v. DIPENTENE, infra*). Nitrosyl chloride passed into a solution of pinene in chloroform at -10° yields a compound $C_{10}H_{16}NOCl$ [103°], which is ppt. as a white crystalline powder on the addition of alcohol (Tilden, *C. J.*, June 1875). The same compound is formed by adding hydrochloric acid to a cooled mixture of the terpene with amyl nitrite and glacial acetic acid (Wallach, *A.* 245, 245). The nitrosochloride gently heated with alcoholic potash yields a nitroso-compound, $C_{10}H_{15}NO$ [129°] (Tilden). For crystallography *v. Story-Maskelyne* (*C. J.*, June 1875, and *Phil. Mag.*). Nitrosopinene unites with two atoms of bromine, forming a crystalline dibromide, which decomposes on melting [132°]. Mixed with alcohol and nitric acid both pinenes form crystallised terpin hydrate $C_{10}H_{16}(OH)_2 \cdot OH_2$ (Wiggers, *A.* 33, 358; 57, 247; Tilden, *C. J.* 83, 247; Hempel, *A.* 180, 71). Pinene dissolved in carbon tetrachloride and mixed with bromine yields a mixture of products, from which a well-defined crystalline dibromide $C_{10}H_{16}Br_2$ [169°-170°] may be isolated. On heating this with aniline it gives up hydrogen bromide, and ordinary cymene is produced. The yield, however, amounts only to about 10 p.c. of the bromide employed (Wallach, *A.* 264, 1). Exposed to the action of air or oxygen, in sunlight, the pinenes produce a crystalline compound $C_{10}H_{16}O_2$ (Sobrero, *C. R.* 33, 66) which when distilled with dilute acid yields a compound called by Armstrong 'Sobrerone' (Armstrong a. Pope, *C. J.* 59, 311), which is identical with one of the products of the action of nitrous acid on pinene, isolated by Wallach a. Otto, and called by them 'Pinol' (*A.* 253, 249). Pinene distilled with bleaching powder and water yields a large quantity of chloroform. Picric acid has no action upon pinenes in the cold, but at the b.p. of the latter a brisk reaction sets in, and if the liquid is afterwards allowed to cool a compound is deposited in colourless scales, which on boiling with alkali yield borneol (Lextreit, *C. R.* 102, 555; Tilden a. Forster, *C. J.* 63, 1388).

2. **Limonene.** This compound, like pinene, occurs in two optically active varieties. Dextro-limonene (175°-176°), S.G. $\frac{20}{20} = 846$, $[\alpha]_D = +106.8$ (Wallach, *A.* 252, 145) occurs in oils of the fruit of oranges and lemons, also in caraway and dill, &c. The most convenient source is the essential oil of sweet orange, *Citrus aurantium*. Lævo-limonene is obtained from the oil distilled from the leaves of *Pinus sylvestris* and *P. picea*. This oil occurs in the drug houses as 'Fir-Wool oil,' but is now much adulterated with common turpentine, and the commercial oil seldom yields more than a small percentage of limonene. (175°-176°), S.G. $\frac{20}{20} = 846$, $[\alpha]_D = -105$ (Wallach, *A.* 227, 287, 246, 221). The limonenes, treated with perfectly dry hydrogen chloride, yield a liquid monochloride. In the presence of alcohol they give, with excess of hydrogen chloride, a quantitative yield of a dihydrochloride [50°], identical with the compound obtained from the pinenes. By the action of nitrosyl

chloride (Tilden a. Shenstone, *C. J.* May, 1877), or by the use of amyl or ethyl nitrite and hydrogen chloride (Wallach), they yield a crystalline nitrosochloride, which, whether formed from dextro- or lævo-limonene, is always a mixture of two isomerides separable from each other by cold chloroform or ether. There are therefore four isomeric limonene nitroso-chlorides, as follows:

FROM *d.* LIMONENE:

α compound [103°-104°] $\alpha_D = +318^\circ$
 β " [105°-106°] $\alpha_D = +240^\circ$

FROM *l.* LIMONENE:

α compound [103°-104°] $\alpha_D = -314^\circ$
 β " [100°] $\alpha_D = -242^\circ$

From the nitroso-chlorides by the action of heat (Tilden a. Shenstone), or by boiling with alcohol (Goldschmidt a. Zürer, *B.* 18, 2220), is produced an isonitroso-limonene, which when made from lævo-limonene is identical in every respect with carvoxim $C_{10}H_{15}N.OH$, from carvol, extracted from oil of caraway (Goldschmidt a. Zürer, *B.* 18, 1732). For a comparison of the rotatory powers of the two limonenes and their derivatives, see Wallach (*A.* 252, 141). The limonenes are further characterised by the formation of a crystalline tetrabromide [104°-105°] by direct addition of bromine (Wallach, *A.* 227, 277).

By mixing together equal quantities of dextro- and lævo-limonenes an optically inactive mixture is obtained, which behaves in many respects as a distinct hydrocarbon, and appears to be identical with dipentene (*q. v.*). Strong sulphuric acid acting upon citrene (*d.*-limonene), causes polymerisation, the chief product being a colophene (310°-320°) (Bouchardat a. Lafont, *C. R.* 115, 1083).

The oil of *Licari kanali* contains a compound, licareol $C_{10}H_{16}O$, from which a hydrocarbon, licarene $C_{10}H_{16}$, is obtainable by the action of acetic anhydride at 150° (Barbier, *C. R.* 114, 674, and *C. R.* 116, 993, and 1062). This terpene appears to consist of impure *d.*-limonene, as it boils at 176°-178°, gives a tetrabromide [103°-104°], forms a nitrosochloride, from which carvoxim [72°] is formed by alcoholic potash; but its specific rotatory power is low, $[\alpha]_D = 7.51^\circ$.

3. **Sylvestrene** occurs in Swedish turpentine (Atterberg, *B.* 10, 1206) and in Russian turpentine (Wallach, *A.* 230, 245), in company with australene and other hydrocarbons of higher boiling-point. (176°-177°). S.G. $\frac{18}{18} = 8510$, $\frac{20}{20} = 8470$. $[\alpha]_D = +66.32$ (Wallach, *A.* 245, 197). The odour of sylvestrene differs from that of pinene and limonene, and resembles the odour of fresh firwood. It forms a liquid monohydrochloride, and a crystalline dihydrochloride [72°], from which the hydrocarbon may be recovered unchanged by heating with aniline. Sylvestrene also gives a nitrosochloride [106°-107°], which, by treatment with alcoholic potash, yields only oily products. The tetrabromide crystallises in monoclinic tables [135°] (Wallach, *A.* 239, 29).

4. **Phellandrene.** The seeds of *Phellandrium aquaticum* were found by Pesci (*G.* 16, 225) to yield about 2½ p.c. of a volatile oil, consisting chiefly of a dextrorotatory terpene (171°-172°). The same hydrocarbon is contained in the oil of bitter fennel, *Feniculum vulgare* (Wallach, *A.*

289, 40), and in the oil of elemi. *Lævo-phellandrene* is found, according to Wallach (A. 246, 282), in the oil of *Eucalyptus amygdalina*. Phellandrene is characterised by the formation of a nitroso-nitrite $C_{10}H_{16}N_2O_2$. Pesci obtains it by the action of a nitrite and dilute sulphuric acid upon the hydrocarbon. It crystallises in needles [94°], and although obtained from the dextrorotatory hydrocarbon it rotates the plane of polarisation to the left. $[\alpha]_D = -183.5^\circ$ (Pesci). By reducing agents this compound is converted into a base $C_{10}H_{16}(NH_2)_2$ (209°-214°). Ammonia converts it into nitrophellandrene $C_{10}H_{16}NO_2$ and an acid.

5. *Dipentene*, formerly called *terpilene* or *terpinylene*. As already stated, this compound is produced when equal quantities of dextro- and lævo- limonenes are mixed together (see *Pentylenes*). It is formed by heating isoprene to a temperature of about 300°. It is also the chief constituent of 'isoterebenthene,' formed by the action of heat on lævo-pinene. It occurs among the products of the destructive distillation of caoutchouc. Dipentene is also produced, together with terpinene, terpinolene, and terpineol, by the action of sulphuric acid or phosphoric acid on terpin, or by the action of sulphuric acid on the pinenes under certain conditions (Armstronga. Tilden, C. J. November, 1879). It is also formed from the dihydrochloride [50°], whether made from pinene or limonene, either by the action of heat upon the chloride alone (Tilden, B. 12, 1133) or by boiling it with a mixture of sodium acetate and acetic acid, or with alcohol and aniline (Wallach). The products thus obtained were formerly supposed to consist of a single hydrocarbon, to which the name 'terpilene' was given. The hydrocarbons known as cinene and cajuputene formed from cineol and cajuputol respectively also consist of dipentene. Dipentene occurs readily formed in the volatile oil of the camphor tree, also in oil of elemi and in Russian and Swedish turpentine (Wallach, A. 227, 296, &c.).

Dipentene boils at about 176°, and has a pleasant smell of lemons. It combines with bromine forming a tetrabromide [124°], and unites with 2HCl forming a chloride [50°], from which it may be regenerated by methods given above. It is to be noted, however, that in all cases more or less isomeric change occurs, and the hydrocarbon, whether reproduced by heat alone or by the action of aniline, always contains terpinene and terpinolene, beside cymene and a small quantity of a paraffinoid hydrocarbon (Tilden A. Williamson, C. J. 63, 292). The nitrosochloride $C_{10}H_{15}NOCl$ yields an inactive carvoxim $C_{10}H_{15}NOH$ [93°] (A. 245, 267). A mixture of equal volumes of dextro- and lævo-limonene behaves in many respects as though it were a distinct hydrocarbon, as it was supposed to be previously to Wallach's researches. Thus the tetrabromide melts at 124°, while the limonene compound melts at 104°. The inactive isonitrosodipentene or carvoxim, melting at 93°, is formed by mixing together equal quantities of lævo-carvoxim [72°] from dextro-limonene and dextro-carvoxim [72°] from lævo-limonene. The resulting compound gives, by Raoult's freezing-point method, a molecular weight corresponding to the simple formula $C_{10}H_{15}NO$ (Wallach, A. 246, 230).

Certain derivatives of dipentene exist in two optically inactive forms. When *d*-limonene-nitrosochloride, prepared from either dextro- or lævo-limonene, is warmed with an alcoholic solution of piperidine, a mixture of two crystallisable nitrolamines is formed in each case, as follows:

NITROLPIPERIDINES $C_{10}H_{15}NONO_2H_{11}$, FROM LÆVOLIMONENE:

- (α) [93°-94°] Rhombic, from alcohol. $[\alpha]_D = -67.60^\circ$. Hydrochloride dextrorotatory.
 (β) [110°-111°]. Monoclinic. $[\alpha]_D = +60.18^\circ$. Hydrochloride almost inactive.

FROM DEXTROLIMONENE:

- (α) [93°-94°]. Rhombic. $[\alpha]_D = +67.95^\circ$. Hydrochloride lævorotatory.
 (β) [110°-111°]. Monoclinic. $[\alpha]_D = -60.48^\circ$. Hydrochloride (?).

When the two α -piperidine bases [93°-94°] are dissolved in petroleum-spirit, and the solutions mixed, an inactive nitrolamine [154°] is at once precipitated. A second inactive compound [152°] is formed by mixing the β -piperidine bases (Wallach, A. 252, 123). Similar results have been obtained by the employment of aniline and benzylamine. The salts of the bases thus produced possess a rotatory power opposite in direction to that of the free base. No method is at present known of producing from limonene active addition-compounds with two molecules of hydrazid. With excess of hydrogen chloride the same inactive dipentene dihydrochloride [50°] is always obtained. The corresponding dihydride seems to crystallise in two forms differing slightly in melting-point (Wallach, A. 239, 18).

6. *Terpinene*. (180° about). This compound is formed, together with dipentene, by the action of acids upon pinene and terpin, &c. It is said to occur in oil of cardamoms (Ev. Weber, A. 238, 98). Terpinene has not been obtained in an absolutely pure state, but is characterised by forming a nitrosanitrite $C_{10}H_{15}N_2O_2$ [155°] (Wallach, A. 239, 33). The tetrabromide is fluid, and it yields no crystallisable hydrochloride. The nitrosanitrite by the action of bases yields nitrolamines $C_{10}H_{15} \begin{smallmatrix} < NOH \\ NH_2 \end{smallmatrix}$ [116°-118°], $C_{10}H_{15} \begin{smallmatrix} < NOH \\ NHC_2H_5 \end{smallmatrix}$ [130°-131°], &c. (A. 241, 315).

7. *Terpinolene*. (185° about). This hydrocarbon is formed along with dipentene and terpinene by the action of acids upon pinene, &c.

With hydrogen chloride and hydrogen bromide terpinolene unites to form the dipentene dihydrochloride [50°] and dihydrobromide [64°]. It forms an optically inactive tetrabromide which crystallises in monoclinic tables [116°] but is gradually converted at ordinary temperatures into a porcelain-like mass.

8. *Fenchene*. A liquid isomeride of camphor (190°-193°), obtained from oil of fennel, is treated with alcohol and sodium, by which it is reduced to the alcohol $C_{10}H_{17}OH$, a colourless crystalline compound. By treating this with phosphoric chloride the chloride $C_{10}H_{17}Cl$ is formed, and from this, by heating with aniline, fenchene $C_{10}H_{16}$ (158°-160°) may be obtained. Fenchene is optically inactive. It differs from other terpenes in resisting the action of nitric acid unless heated (Wallach, A. 263, 149).

SYNOPSIS OF TERPENES AND THEIR CHIEF DERIVATIVES.

Isoterpenes.

Camphenes $C_{10}H_{16}$. Pinene monohydrochloride [125°] was formerly described under the name 'artificial camphor,' from its resemblance to camphor in appearance and to a certain extent in odour. This compound is remarkably stable, but may be decomposed by heating with sodium stearate or benzoate, with potassium acetate, with alcoholic potash, or, better, with a mixture of sodium acetate and alcoholic soda (Brühl, *B.* 25, 147). The resulting hydrocarbon is a camphene [51°-52°] (160°), dextro- or lævorotatory or inactive according to the nature of the hydrochloride used and the reagent employed, though the exact conditions which determine the production of one or other are scarcely known (Riban, *A. Ch.* [5] 6, 353).

Camphene is also formed from bornylchloride by the action of alcoholic potash (Riban), by the action of water and magnesia (Kachler, *A.* 197, 86), or by heating with aniline to the boiling-point of the latter (Wallach, *A.* 230, 234); it is also formed from camphor chloride and from pinene hydrochloride by the action of sodium (Montgolfier, *C. R.* 89, 102). In the last case it is accompanied by a liquid hydrocarbon (170°), $C_{10}H_{20}$, which behaves like a paraffin, and is probably identical with a liquid obtained by the action of hydrogen iodide on turpentine (Berthelot), also by the action of iodine (Armstrong a. Gaskell, *B.* 12, 1756) and by the action of sulphuric acid on turpentine (Armstrong, *B.* 12, 1759).

Camphene is also formed by the action of strong sulphuric acid on turpentine, and constitutes the characteristic ingredient in the liquid formerly known as 'terebene' (Armstrong a. Tilden, *C. J.* 1879, 733).

Camphene closely resembles camphor in appearance and even somewhat in odour. It is soluble in alcohol, ether, and benzene, and crystallises in leaflets from a concentrated solution. It is incapable of combining with bromine, but it forms a compound [157°] with hydrogen chloride, which is distinguished from pinene hydrochloride by its instability, being rapidly

decomposed by water with reproduction of camphene (Riban, *C. R.* 80, 1830). It is also dissociated into camphene and hydrogen chloride when volatilised (Ehrhardt, *C. N.* 54, 239). Camphene hydrochloride is said to be identical with bornyl chloride (Kachler a. Spitzer, *A.* 200, 340; v. also Brühl, *B.* 25, 160). Camphene does not combine with nitrosyl chloride. In contact with bromine it is slowly attacked, forming an oily monobromo- derivative (230°-240°).

Oxidised by chromic liquor, camphene yields camphor, dextro-, lævorotatory or inactive according to the character of the camphene.

By the action of phosphorus pentachloride on camphene, and subsequent treatment of the mass with an alkaline solution, salts of two phosphonic acids are formed (Marsh a. Gardner, *C. J.* 65, 35).

When camphene is heated to about 300° it is converted into liquid products which seem to include dipentene, but have not been sufficiently investigated.

Homologues of camphene.

Ethyl-camphene obtained by the conjoint action of sodium and ethyl iodide upon camphor monochloride $C_{10}H_{15}Cl$, is a colourless mobile liquid having a smell like turpentine (197°-199°-9°, bar. 742.1 mm.). Isobutyl-camphene is also a liquid (228°-229°, bar. 750.4 mm.) (Spitzer, *B.* 11, 1817).

Sesquiterpenes $C_{15}H_{24}$.

Oils of clove, calamus, cascarrilla, patchouli, and cubeba contain a hydrocarbon of this composition (Gladstone, *C. J.* 1872), as also do the oils of gambanum, and savin and 'huile de cade,' a kind of tar made by distillation of the wood of *Juniperus oxycedrus* (Wallach, *A.* 238, 81). The hydrocarbon obtained from cade or cubeba (274°-275°) (S.G. $\frac{4}{4}$ = .921) forms the following crystalline compounds: $C_{15}H_{24}2HCl$ [117°-118°], $C_{15}H_{24}2HBr$ [124°-125°], $C_{15}H_{24}2HI$ [105°-106°]. The hydrocarbon, especially when partially resinsified by exposure to the air, gives the following characteristic colour reaction: dissolved in chloroform or glacial acetic acid and then

shaken up with a few drops of strong sulphuric acid, the liquid assumes an intense green and then blue colour, which, when heated, passes into red (Wallach). An attempt to prepare from isoprene a polymeric of the composition $C_{11}H_{24}$ proved unsuccessful (Wallach).

Conimene $C_{15}H_{24}$, a liquid (264°) having a pleasant odour, is obtained from the incense resin (*Icica heptaphylla*) of British Guiana (Stenhouse & Groves, *C. J.* 1871, i. 175).

Polyterpenes $C_{20}H_{32}$, &c.

This group includes (1) the constituents of certain natural essential oils; (2) products of artificial polymerisation of terpenes; and (3) caoutchouc and guttapercha.

1. Oleo-resin or so-called 'balsam' of copaiba (*Copaifera Langsdorffii* and other species) is a mixture of a resin with an oil (250°-260°). The latter unites with water and absorbs hydrogen chloride, with production of a deep violet colour but no crystalline hydrochloride. A similar hydrocarbon is obtained from Gurjun balsam or 'wood oil,' the product of various species of *Dipterocarpus* growing in the East, and from other essential oils.

2. When turpentine oil and other terpenes are heated for some time to about 300°, or treated with concentrated sulphuric or phosphoric acid or other agents, a large part of the hydrocarbon undergoes polymerisation. The name 'colophene' was given by Deville to the less volatile portions of the product obtained in this manner from French turpentine, apparently under the impression that it was closely related to the oil obtained by distillation of resin. Resin-oil, however, contains oxygen, and exhibits quite different characters.

Colophene is a yellowish viscous fluid, usually

fluorescent, which begins to boil at about 800°, but the distillation even under reduced pressure is attended by decomposition. The boiling-point continually rises, and even at a temperature approaching dull redness a viscid residue is left which on cooling becomes nearly solid (Armstrong & Tilden, *C. J.* Nov. 1879). The portions which distil at 800° and upwards appear to consist of saturated compounds, for they absorb mere traces of hydrogen chloride. By the action of antimony trichloride upon turpentine a solid, $C_{10}H_{16}$, is formed. This combines with hydrogen chloride to form two compounds $C_{10}H_{16}HCl$, and $C_{10}H_{16}2HCl$ (Riban, *C. R.* 1874, 889).

3. CAOUTCHOUC *v.* vol. i. p. 677. For further information concerning the products of its decomposition by heat *v.* PENTINENES (vol. iii. p. 807) and DIPENTENE (*supra*).

GUTTAPERCHA, *v.* vol. ii. p. 658.

Caoutchouc is formed from isoprene by polymerisation, which sometimes occurs spontaneously under circumstances not fully understood (Tilden, *C. N.*, May 1892).

Oxidised compounds connected with terpenes.

A considerable number of oxidised compounds are known which are evidently closely connected with the terpenes, and in many cases directly derivable from them. Some of these, as, for example, borneol and camphor, occur as natural products in essential oils; others, such as terpin, are the products of the addition of water to a terpene, or, like camphor and some of its isomerides, may be formed from terpenes by oxidation. These compounds are enumerated in the following table, together with the hydrocarbons with which they are presumably immediately connected.

Hydrocarbons	Alcohols	Glycols	Ketones (?)
Cymene $C_{10}H_{14}$ (ii. 361)	Carveol $C_{10}H_{18}OH$ (i. 711)	—	Carvol $C_{10}H_{16}O$ (i. 711)
Pinene $C_{10}H_{16}$ (<i>v. supra</i>)	Myristicol and absinthol (<i>v. infra</i>)	Sobrerol $C_{10}H_{18}(OH)_2$ (<i>v. infra</i>)	Sobrerone (pinol) $C_{10}H_{16}O$ (<i>v. infra</i>)
Dipentene $C_{10}H_{16}$ (<i>v. supra</i>)	Terpineol $C_{10}H_{17}OH$ (<i>v. infra</i>)	Terpin $C_{10}H_{18}(OH)_2$ (<i>v. infra</i>)	—
—	Cineol $C_{10}H_{17}OH$ (ii. 187). Syn. Eucalyptol, cajuputol	—	—
Fenchene $C_{10}H_{16}$ (<i>v. supra</i>)	Fencheol $C_{10}H_{17}OH$ (<i>v. infra</i>)	—	Fenchone $C_{10}H_{16}O$ (<i>v. infra</i>)
Camphene $C_{10}H_{16}$ (<i>v. supra</i>)	Borneol $C_{10}H_{17}OH$ (i. 522)	Camphene glycol $C_{10}H_{18}(OH)_2$ (<i>v. infra</i>)	Camphor $C_{10}H_{16}O$ (i. 669)
—	Geraniol $C_{10}H_{17}OH$ (ii. 609)	—	Pulegone $C_{10}H_{16}O$ (<i>v. infra</i>)
—	Linalool $C_{10}H_{17}OH$ (iii. 146)	—	Puleone $C_{10}H_{18}O$ (<i>v. infra</i>)
—	—	—	Tanacetone or Thujone $C_{10}H_{16}O$ (<i>v. infra</i>)
Menthene $C_{10}H_{16}$ (iii. 202)	Menthol $C_{10}H_{18}OH$ (iii. 203)	—	Menthone $C_{10}H_{18}O$ (iii. 204)
Dihydrocamphene $C_{10}H_{18}$ (<i>v.</i> DECYLENE, ii. 867)	—	—	—
Tetrahydrocamphene $C_{10}H_{20}$ (<i>v.</i> DECYLENE, ii. 869, <i>et infra</i>)	—	—	—

Cymene $C_{10}H_{14}$ (176°); ii. 861.

Dipentene $C_{10}H_{16}$ (176°); v. *supra*.

Fenchene $C_{10}H_{16}$ (160°); v. *supra*.

Camphene $C_{10}H_{16}$ (160°); v. *supra*.

Menthene $C_{10}H_{16}$ (167°); iii. 202.

Dihydrocamphene $C_{10}H_{18}$, v. DECAENE, ii. 867.

The liquid produced, together with the solid monohydrochloride, by passing hydrogen chloride into pinene, yields when treated with sodium a mixture from which a liquid hydrocarbon $C_{10}H_{18}$ (148°–149°), having a smell of oranges, may be separated by fractionation, &c. (Bouveault, *C. R.* 116, 1067).

Tetrahydrocamphene $C_{10}H_{20}$ (DECYLENE, ii. 367). A liquid obtained by the action of hydrogen iodide and phosphorus upon oil of turpentine (Berthelot) and another (160°) by action of phosphonium iodide on turpentine (Baeyer) have this composition. The same formula is ascribed by Armstrong (*B. 12*, 1758) to a liquid (160°–170°) obtained by the action of iodine upon oil of turpentine and upon camphor, also by the action of sulphuric acid upon turpentine. All these products are insoluble in strong sulphuric acid, and resemble the paraffins in chemical characters.

Carveol $C_{10}H_{18}OH$ (219°); i. 711.

Terpineol $C_{10}H_{18}OH$. [35°]. (215°–218°). Wiggers, *A. 33*, 358; 57, 247; List, *A. 67*, 362; Tilden, *C. J.* 33, 247, and 35, 286; Wallach, *B.* 18, 618, Ref.; Kannonikoff a. Flawitzky, *J. pr.* [2] 32, 497; Bouchardat a. Voiry, *C. R.* 104, 996. Dextro- and laevo-terpineol are obtained by the action of alcoholic sulphuric acid upon *d*- and *l*-pinene respectively, or inactive by distilling terpin with very dilute sulphuric or hydrochloric acid. Terpineol as thus obtained is a viscous liquid, having an odour of white lilac. By fractional distillation under reduced pressure a portion is obtained (130°–135° at 40 m.m.), which may be crystallised by cooling to –50°, or by the introduction of a crystal of the same. These crystals melt at 30°–32°, and boil undecomposed at 218° (Bouchardat a. Voiry, *C. R.* 104, 996). Terpineol treated with sodium evolves hydrogen, but in consequence of its viscosity the action soon ceases. Contact with dilute acids converts terpineol into terpin hydrate. Hydrogen chloride and iodide react to form $C_{10}H_{17}Cl_2$ [50°] and $C_{10}H_{17}I_2$ [77°] respectively. Potassium hydrogen sulphate at 200° produces dipentene. Terpineol unites with two atoms of bromine, but excess of bromine gives rise to dipentene tetrabromide. With phenyl cyanate it yields phenylterpinyl-urethane $C_{10}H_{17}NH.CO.OC_6H_5$, [110°]. These and other reactions have been repeated by Wallach, using crystallised terpineol (*A.* 275, 103). Terpineol oxidised by permanganate yields a substance $C_{10}H_{16}O_2$ [121°–122°], which probably has the constitution of an oxyterpin $C_{10}H_{17}(OH)_2$. Further oxidised by means of chromic acid this yields a crystalline compound $C_{10}H_{16}O_3$ [62°–63°] (Wallach, *A.* 275, 146).

Cineol $C_{10}H_{18}O$ (176°); ii. 187. Cineol appears to contain no hydroxyl, since it is not acted upon by metallic sodium nor by benzoyl chloride at 120°. It is also unaffected by hydroxylamine and by phenylhydrazine. Hence it appears to be neither an alcohol nor a ketone. Its relation to terpineol (*infra*) is shown by the fact that when heated with

alcohol and sulphuric acid cineol is converted into terpinene and terpinolene: also that terpineol, and therefore also terpin, are partly converted into cineol by prolonged heating with phosphoric acid. Cineol oxidised by permanganate of potassium yields the potassium salts of carbonic, oxalic, and cineolic acids, with a small quantity of acetic acid. Cineol yields 45 p.c. of its weight of cineolic acid. This compound forms well-defined anhydrous crystals, which dissolve in 70 pts. of water at 15°, and in 15 pts. at 100°. They melt with decomposition at 196°–197°.

Calcium cineolate $C_{10}H_{17}CaO_4.4H_2O$ is soluble in cold water, but is completely precipitated by boiling the aqueous solution. Silver cineolate $C_{10}H_{17}AgO_4.H_2O$ is soluble in both water and alcohol, but cannot be crystallised. Ethyl cineolate $C_{10}H_{17}(C_2H_5)_2O_4$, obtained by passing hydrogen chloride gas into an alcoholic solution of the acid, is a colourless liquid (155° under 11–12 mm.). By dry distillation cineolic acid yields cineolic anhydride, water, carbon dioxide, and a liquid which appears to consist of a monobasic acid (*A.* 246, 265).

Fenchol $C_{10}H_{17}(OH)$. Fenchyl alcohol [40°–41°]. (201°). (Wallach, *A.* 268, 143; 272, 99–125). S.G. d_4^{20} .933 (W.). $[\alpha]_D^{20} = \pm 10.36$ (W.). Dextro- and laevo-fenchyl alcohols are obtained by the reduction with sodium and alcohol of laevo- and dextro-fenchones respectively. Concentrated HNO_3 oxidises *l*-fenchyl alcohol to *d*-fenchone. PCl_5 gives rise to fenchyl chloride $C_{10}H_{17}Cl$ (84°–86° at 14 mm.).

Borneol $C_{10}H_{17}OH$, i. 522.

Geraniol $C_{10}H_{17}OH$, ii. 609.

Linalool $C_{10}H_{18}OH$, iii. 146. Linalool is said to be convertible into the isomeric geraniol by treatment with acetic anhydride, and saponifying the resulting ester with alcoholic potash (Bouchardat, *C. R.* 116, 1253).

Menthol $C_{10}H_{18}(OH)$, iii. 203.

Terpin $C_{10}H_{16}(OH)_2$ [104°–105°]. (258°) (Wiggers, *A. 33*, 358; 57, 247; Tilden, *C. J.* 33, 247; 35, 286; Wallach, *A.* 230, 225–272). Terpin is best known in the form of its hydrate $C_{10}H_{20}O_2.H_2O$ [116–117°], a beautifully crystalline compound which on heating to 100° loses water and leaves terpin as a vitreous mass. Terpin hydrate is readily obtained by shaking turpentine oil with alcohol acidified with sulphuric or nitric acid (Flawitzky, *B. 12*, 1022; Tilden, *C. J.* 33, 247; 35, 286), and leaving the liquid to evaporate. It is an optically inactive, saturated compound, slightly soluble in boiling water, soluble in alcohol and crystallising in rhombic prisms (Rammelsberg, *P.* 63, 570; Maskelyne, *P. M.* 1879). It possesses the characters of a glycol and with hydrogen chloride yields dipentene dihydrochloride [50°]. Boiled with water containing a mere trace of mineral acid, terpin dissolves with production of terpineol and water.

Camphene glycol $C_{10}H_{16}(OH)_2$. [192°] (G. Wagner, *B.* 23, 2311).

Formation.—By the oxidation of camphene in benzene solution with a 1 p.c. solution of $KMnO_4$ (*l.c.*).

Properties.—Colourless prismatic needles (from benzene) very readily soluble in ether, alcohol, CS_2 , and chloroform. Exhibits the

same phenomenon as camphor when thrown on water. Sublimes when heated above 100° . Melts when warmed with water, but only dissolves in it with difficulty. Heated with acetic anhydride in a closed tube at 120° , the greater part loses water, only a small portion being converted into the acetic ester. Treatment with dilute HCl results in the loss of 1 mol. of H_2O , giving rise to a solid body, $C_{10}H_{16}O$, isomeric with camphor, which reduces ammoniacal $AgNO_3$ and reacts with hydroxylamine.

Carvol $C_{10}H_{16}O$ (228°), v. i. 711.

Fenchone $C_{10}H_{16}O$. [5° - 6°]. (192° - 198°) (Wallach, A. 263, 130; 272, 102). S.G. Δ^2 9465 (W.). R_A 44-23 (W.). [α_D] $+71.70$ and -66.94 .

Occurrence.—Dextro-fenchone is present in fennel oil, the fraction boiling between 190° and 195° consisting almost exclusively of the ketone, together with traces of anethol; derived from Thuja oil, fenchone possesses laevorotatory optical properties. *D*- and *L*-fenchone form a series of derivatives which bear to one another a relation similar to that subsisting between the two tartaric acids, and the analogy extends to the formation of racemic modifications when equal proportions of the two classes of derivatives are mixed together.

Preparation.—The fraction of fennel oil boiling between 190° and 195° is treated with concentrated HNO_3 , the ketone remaining unattacked. After being freed from acid and distilled in a current of steam, the dry oil is cooled, and the fenchone crystallises out.

Reactions.—With bromine in the cold, an addition compound is formed, substitution taking place if the mixture becomes heated. P_2O_5 , P_2S_5 , and PCl_5 have the same action upon fenchone as upon camphor. Fenchone is dissolved by cold concentrated HCl, being thrown out of solution on warming. HNO_3 has but little action in the cold, but in a sealed tube at 120° HCN is formed (A. 263, 134). $KMnO_4$ oxidises fenchone to a mixture of oxalic, acetic, and dimethyl-malonc acids. *D*- and *L*-fenchone yield *d*- and *L*-fenchyl alcohols respectively on reduction with Na and alcohol (v. *Fenchol*). On heating *d*- and *L*-fenchone with ammonium formate, *L*- and *d*-fenchylamines respectively are formed. Fenchone does not react with phenyl-hydrazine or with alkaline sulphites, but both varieties form oxims [161°] with hydroxylamine.

d-Fenchon-oxim $C_{10}H_{16}NOH$ [161°] (240°) loses water on treatment with dilute H_2SO_4 , an unsaturated dextrorotatory nitrile (218°) being formed.

L-Fenchon-oxim $C_{10}H_{16}NOH$ [161°] behaves in a similar manner on treatment with dilute H_2SO_4 . The resulting nitrile yields with potash a laevorotatory α -isoxim $C_8H_{12}CONH_2$ [114° - 115°] which is readily converted by dilute H_2SO_4 into the β -isoxim [136° - 137°].

Camphor $C_{10}H_{16}O$ (i. 669).

Menthone $C_{10}H_{16}O$ (206°) (iii. 204).

Pulegone $C_{10}H_{16}O$. (130° - 131° under 60 mm.). (Beckmann A. Pleissner, A. 262, 1; Wallach, A. 272, 122; Semmler, B. 25, 3515). S.G. Δ^2 9323 (B. a. P.); R_A 45-55 (B. a. P.); [α_D] 22.89 (B. a. P.). Pulegone is the chief constituent of Spanish oil of pennyroyal (*Mentha pulegium*). It is a dextrorotatory colourless liquid, having

an odour of peppermint, and rapidly becoming yellow on exposure to the air.

Reactions.—With HBr it combines forming a laevorotatory [α_D] -33.8) addition compound $C_{10}H_{16}O.HBr$ [40.5°]. When heated with ammonium formate, Wallach (A. 272, 123) failed to obtain a base isomeric with fenchylamine and thujonamine, a mixture of bases being formed. Slow oxidation with $KMnO_4$ gives rise to acetone and β -methyl-adipic acid [84.5°]. Rapid oxidation with the same reagent yields a γ -valero-lacton- γ -acetic acid (Semmler, B. 25, 3516). Pulegone combines with hydroxylamine to form pulegonoxim $C_{10}H_{16}NO$ [157°]. The oxim contains one molecule of H_2O more than camphoroxim. It is laevorotatory ([α_D] -83.4) and forms a hydrochloride [117° - 118°], a benzoyl ester [137° - 138°], and an acetyl ester [149°]. On heating its hydriodide pulegonamine $C_{10}H_{16}O.NH$ is formed.

Pulegone hydrobromide $C_{10}H_{16}O.HBr$ [40.5°] is laevorotatory; it forms an oxim [38°] which becomes converted on standing into normal pulegonoxim [157°]. Pulegone hydrobromide, on treatment with moist silver or lead oxide, loses HBr, pulegone being regenerated. Distillation with zinc-dust gives rise to an oil which resembles menthone in every respect but the melting-point of its oxim (85° instead of 59°).

Constitution.—From the results of oxidation experiments carried on under various conditions with $KMnO_4$, Semmler (B. 25, 3519) attributes to pulegone the constitution:

Puleone is the name given to a compound isomeric with camphor, obtained by Barbier (B. 25, 110c), from pennyroyal oil, described as boiling at 222° - 223° , and possessing the following physical properties: S.G. 9482; Δ^2 9293; [α_D] $+29.15$. Its oxim $C_{10}H_{16}NOH$ is an oil (170° under 48 mm.) yielding a liquid anhydride $C_{10}H_{14}N$ on treatment with dilute H_2SO_4 . Chromic acid mixture oxidises it to carbonic, acetic, and propyl-succinic [89° - 91°] acids.

Tanacetone $C_{10}H_{16}O$ (195° - 196° ; 84.5 at 13 mm.), identical with the thujone of Wallach (A. 272, 109; Bruylants, B. 11, 450; Semmler, B. 25, 3348, 3519; Wallach, l.c.). S.G. Δ^2 9126 (S.). R_A 44-54 (S.).

Tanacetone occurs in tansy, sage, wormwood, and thuja oils. It has ketonic properties, and possesses an optical rotatory power amounting to $+38.30'$ in a 2-dm. column.

Reactions.—Sodium in alcoholic solution reduces it to tanacetyl alcohol (92.5° at 13 mm.). With alkaline hypobromite it yields bromoform and tanacetogen-dicarboxylic acid (113.5° at 15 mm.). Oxidised with $KMnO_4$, it yields tanacetocarboxylic acid, which exists in two modifications, the α and β thujaketonic acids of Wallach (l.c.), [75° - 76°] and [78° - 79°] respectively. Heated with ammonium formate, it gives tanacetylamine (198° - 199°), the same body being formed when tanacetoxim (see below) is reduced with sodium and alcohol. The hydrochloride of

this base on dry distillation yields tanacetene (172°-175°), a hydrocarbon of the formula $C_{10}H_{16}$, identical with Wallach's thujene. Tanacetone reacts with hydroxylamine to form tanacetoxim $C_{10}H_{15}NOH$ [51.5°] (185°-186° at 22 mm.), which yields tanacetylamine on reduction, while treatment with dilute alcoholic H_2SO_4 converts it into a cymidine (Pr:NH₂:Me:1:3:4), which gives carvacrol with nitrous acid. Tanacetophorone $C_{10}H_{16}O$ (89°-90° at 13 mm.). R_d 37.6. When tanacetogen-dicarboxylic acid (produced by the action of NaBrO upon tanaceto-carboxylic acid) is heated with soda-lime, tanacetophorone is formed. It has ketonic properties, and combines with hydroxylamine.

Constitution.—Semmler (B. 25, 3519) suggests for tanacetone and tanacetogen-dicarboxylic acid the formulæ

Sobrerone $C_{10}H_{16}O$. *Pinol*. (183°-184°) (Wallach, A. 253, 254; Armstrong, C. J. Proc. 1890, 100). S.G. 22.953 (W.); μ_D 1.469 (W.). Sobrerone is obtained from the mother-liquors accumulated in the preparation of pinene nitroso-chloride; also by boiling sobrerol with dilute H_2SO_4 (Armstrong, Lc.).

Reactions.—It combines readily with Br to form a dibromide [94°], from which, on treatment with alcoholic potash, sobrerone is regenerated. Sobrerone and its dibromide yield terebic acid [175°-176°] on oxidation with $KMnO_4$. HNO_3 produces the same result. It forms a nitroso-chloride [103°] which, by the action of bases, is readily converted into nitrolamines, e.g. sobrerone-nitrol-piperidine [154°] and sobrerone-nitrol-benzyl-amine [133°-134°]. The dibromide $C_{10}H_{16}O.Br_2$ [94°] (143°-144° at 11 mm.) yields on treatment with alcoholic potash, in addition to sobrerone, its glycol-ether $C_{10}H_{18}O(OC_2H_5)_2$ [52°-53°]. Sobrerone-glycol-diacetate is easily obtained by heating the dibromide to 150° with lead acetate in glacial acetic acid solution. When heated at 100° for three hours with formic acid, sobrerone dibromide is converted into pinene.

Constitution.—Its behaviour towards bromine and nitrosyl chloride and its molecular refraction indicate the existence of one ethylene linking, while its indifference towards acid chlorides, hydroxylamine, phenylhydrazine and H_2S render it probable that the O-atom is united to two different C-atoms. From these facts, and from its behaviour on oxidation, Wallach (A. 253, 259) assumes the constitution

Sobrerol $C_{10}H_{16}O_2$ [150°] (Sobrero, C. R. 33, 66; Armstrong, C. J. Proc. 1890, 100; C. J. 59, 315). Sobrerol is obtained by oxidising French and American turpentine in

sunlight. It occurs in two optically active forms, both melting at 150°, and on allowing a mixed solution to crystallise inactive sobrerol [131°] separates out. When boiled with dilute H_2SO_4 it loses 1 mol. of H_2O , sobrerone—identical with Wallach's pinol—being formed.

Eucalyptol $C_{10}H_{18}O$ (176°) (Jahns, B. 17, 2941; Bouchardat a. Voiry, C. R. 106, 663). Identical with cineol, spicool, cajeputol, and terpan (B. a. V.).

Myristicol $C_{10}H_{18}O$ (224°) (Wright, B. 6, 1320; Gladstone, C. J. 23, 147; 25, 1; Brühl, B. 21, 471). S.G. 22.9446 (G.). R_d 46.42 (G.). Myristicol is a dextrorotatory alcohol, obtained from the ethereal oil of nutmeg, *Myristica aromatica*. It yields a chloride with PCl_5 , and is converted into cymene by the action of $ZnCl_2$.

Absinthol $C_{10}H_{16}O$ (217°) (Beilstein a. Kupfer, B. 6, 1183; Wright, Lc. 1320; Gladstone, C. J. 45, 241; Brühl, B. 21, 471). S.G. 23.9128 (G.). R_d 44.62 (G.). Absinthol is obtained from oil of wormwood, and is dextrorotatory. It is converted by $ZnCl_2$ and P_2S_5 into cymene. In what form the oxygen exists is at present unknown.

Constitution of the terpenes.

I. Pinene. The following facts must be taken into consideration:—

1. Dry pinene combines with one molecule of hydrogen chloride to form a saturated compound, from which hydrogen chloride is withdrawn with difficulty, the resulting hydrocarbon being a solid camphene. Moist pinene combines with $2HCl$, yielding dipentene-dihydrochloride. This also is saturated. The formation of both these compounds is undoubtedly attended by isomeric change, inasmuch as pinene cannot be recovered from either of them; but on removal of the elements of hydrogen chloride a new hydrocarbon results.

2. Pinene seems to combine with two atoms or with four atoms of bromine, according to the method of operating. By adding bromine to a cooled solution of pinene in carbon tetrachloride, Wallach has obtained a crystalline dibromide $C_{10}H_{16}Br_2$ [170°]. The yield is, however, very small, about 7 p.c. of the hydrocarbon employed (A. 264, 1). By shaking up a solution of pinene in chloroform, with an excess of sodium hypobromite, acidified with hydrochloric acid, so as to liberate the bromine, and immediately afterwards determining the unabsorbed excess of bromine, Tilden obtained results which pointed to the union of the terpene with four atoms of bromine. The combination is, however, very unstable, and hydrogen bromide is soon evolved (C. J. 53, 882). Schtschukaroff finds that a chloroform solution of pinene takes up, in the dark, four atoms of bromine; but the bromide formed is unstable, and quickly gives off hydrogen bromide, thus $C_{10}H_{16}.Br_4 = HBr + C_{10}H_{15}.Br_3$ (B. 23, 432, Ref.; J. pr. 47, 191-6).

3. Pinene combines with $NOCl$ to form a saturated compound which is not an oxim but a nitroso-compound, and yields up the $NO.Cl$ by the action of aniline, with liberation of an optically inactive pinene.

4. By addition of two atoms of bromine to pinene, and subsequently heating the product

alone, or, better, with aniline (Oppenheim, *B. 5*, 429), cymene is formed.

5. In contact with slightly diluted mineral acids, or when heated above its boiling-point, pinene is gradually converted into an optically inactive mixture of dipentene with terpinene, terpinolene, and polymerised terpene ('colophene').

6. When heated to a temperature short of visible redness, pinene yields a considerable quantity of isoprene C_5H_8 , together with a notable amount of *meta*-xylene.

7. Pinene submitted to oxidation yields about 1 p.c. of its weight of *p*-toluic or terephthalic acid. This is perhaps due to the presence of a little cymene. It must, however, be remembered that the oxidising agent usually employed is either nitric acid or acidified chromic liquor, and hence that the pinene is first changed into dipentene or one of the other hydrocarbons referred to above (5). When nitric acid is used oxalic acid is the most abundant product, accom-

panied by terebic acid

and dimethylfumarc acid

By treatment with chromate and sulphuric acid pinene yields much acetic acid, together with some terebic acid and

terpenylic acid

8. Natural pinene rotates the plane of polarisation to the right or to the left. It therefore must be supposed to contain an asymmetric atom of carbon.

In order to epitomise these facts many formulæ have been proposed. The most important fall under two classes—namely, those in which pinene is represented as a dihydrocymene, and those in which a cross- or para-linkage is assumed.

Of the former class, the first example is the formula given many years ago by Oppenheim (*B. 5*, 98)—

This kind of formula is now attributed with greater probability to limonene, and it must be remarked that of the possible formulæ of this type there are only four which contain an asymmetric carbon atom and *iso*-propyl.

It has been shown that cymene, with which pinene is closely connected, contains *iso*- and not normal propyl (Widman, *B. 24*, 439). Hence pinene and its isomerides are believed also to be isopropyl compounds.

Formulæ containing cross- or para-linkages have been proposed as follows:—

Kannonikoff
(*J. pr. 32*, 517)

Wallach
(*B. 24*, 1539)

Wallach (*A. 289*, 49)
Collie (*B. 25*, 1108)

Wagner
(*B. 24*, 2187)

II. Limonene.—1. Dry limonene combines with one molecule of hydrogen chloride, but unlike the hydrochloride derived from pinene the resulting compound is optically active and is not saturated, as it combines with halogens, with nitrosyl chloride, and, in the presence of moisture, with a second molecule of hydrogen chloride (Wallach, *A. 270*, 188). Limonene in the presence of water or alcohol readily yields dipentene dihydrochloride [50°], identical with the product formed from pinene. The dihydrochloride is optically inactive.

2. Limonene unites with four atoms of bromine, forming a crystalline tetrabromide.

3. Limonene unites with one molecule of nitrosyl chloride. The product, of which two (stereo?) isomerides occur, gives the reactions of an oxim.

4. Limonene readily yields abundance of cymene identical with that which is obtained from pinene (Oppenheim, *B. 5*, 628).

5. Limonene is polymerised by heat much less readily than pinene, and is not convertible into camphene.

6. Limonene vapour at a low red heat yields isoprene in the same way as pinene.

7. Limonene oxidised by nitric acid or by chromate yields oxalic, acetic, terebic or terpenylic acids according to circumstances, usually without any trace of toluic or terephthalic acid.

8. Limonene is dextro- or levo-rotatory. Δ

mixture of equal volumes of the active hydrocarbons constitutes dipentene, which, on account of its peculiarities, quite different from those of its components, was long regarded as a distinct hydrocarbon.

The formula which agrees best with the characters of limonene is either I. or II. given above (see *Pinene*).

In both of these there is an asymmetric carbon atom, and as the mono-hydrochloride is optically active while the dihydrochloride is inactive, these compounds will probably be represented by the following formulæ:—

Limonene nitrosochloride deprived of the elements of hydrogen chloride yields a compound which has been identified with carvoxim. If the following formulæ be assumed for carvacrol and carvol, the interrelation of these compounds is obvious.

The corresponding formula for limonene should be No. II., but if that correctly represents the constitution of the hydrocarbon, the production of the nitrosochloride, or of the oxim from it, must be attended by isomeric change involving a re-distribution of the hydrogen and of the double linkages. Thus:—

The oxim is optically active.

The very ready conversion of pinene into dipentene (= limonene) is a point of considerable importance, and it appears probable that the products formed by the action of heat and acid oxidising agents are in reality derived, not directly from pinene, but from the isomeric hydrocarbon into which it is first converted. The splitting up of pinene by heat into isoprene has been regarded (Wallach, *A.* 239, 48; Collie, *B.* 25, 1111) as supporting the formulæ already given VI. and VII., in which a para- or cross linkage is adopted. But remembering that isoprene is converted by polymerisation, not back again into pinene, but into dipentene, this evidence is of little importance. On the other hand, the difficulties involved in the assumption of a cross link in a cycloid of six carbon atoms are very considerable. In any closed ring of carbon atoms, the stability of the ring is easily accounted for upon simple mechanical principles. For if we consider six carbon atoms situated at the angles of a regular hexagon, and each attracted to its two neighbours on either side, whatever be the forces of attraction between them the resultant of those forces will have the effect of urging each carbon atom toward the centre of the figure. Thus, if the carbon atom *a* is attracted towards the carbon atom *b* with a force represented by *p*, and towards *c* with a force represented by *p'*, in the figure, the resultant of these two pressures will be *r*, which acts towards the centre; and so with each of the five other atoms.

This conception is, of course, independent of any hypothesis concerning the fourth unit of valency, and the formula has no reference to the well-known 'centric' formula. The modern hypothesis according to which the carbon atom is supposed to be situated at the centre of a regular tetrahedron while the radicles with which it is united are placed at the angles of the same supplies no distinction between the force and the direction of the unit of affinity. The difference of specific volume observed between carbon compounds of the aromatic and fatty series seems to indicate that carbon atoms in the former are more closely united together, but it appears that no compounds are known in

which the specific volume of carbon differs very greatly from its normal value. Hence it appears probable that the carbon atom, in uniting with other atoms, preserves a nearly constant distance from them, and in the figure above to suppose that *a* is combined with *d* as firmly as with *b* or *c* requires the assumption that a carbon atom is capable of acting through a distance twice as great in one case as in another. If this is possible, and we imagine the force of attraction between *a* and *d* to be as great as between *a* and *b* or *c*, then, unless *c* acts upon *e* and *b* acts upon *f* at the same time with the same force the figure will be changed from the hexagon to a double square.

A compound of this kind would be incapable of many of the changes which are characteristic of pinene, and a second cross linkage between *c* and *e*, or between *b* and *f*, would be impossible. Hence the following formulae, which are attributed by Wallach to nitrosopinene and pinylamine cannot be accepted even if a single diagonal is allowed in the formula of pinene.

Formulae III. and IV. now remain to be considered. So far as the writer is aware, formulae of this type have not been proposed for any of the terpenes. Nevertheless there is much to be said in favour of an expression of this kind for a compound so unstable as pinene, which appears to be incapable of withstanding the action of heat or of contact with any reagent without isomeric change. For example, the conversion of pinene into dipentene, terpinene, and terpinolene may be explained with the minimum amount of hypothesis by the following formulae, in which the tendency towards the conversion of an unsymmetrical into a symmetrical molecule is clearly shown. The question as to the relative positions of the methyl and propyl groups is left open.

The conversion of pinene into dipentene through the dihydrochloride is readily shown.

Such a formula for pinene also explains the extreme instability of its tetrabromide.

III. CAMPHENE. Camphene behaves towards all reagents—such as bromine and nitrosyl chloride—as a saturated compound, but with hydrogen chloride it unites, forming a compound which in external appearance resembles pinene monochloride, but differs from that compound by its instability. When camphene is oxidised by chromic acid it yields camphor, but when treated with permanganate a glycol is formed. This compound crystallises in odourless small monoclinic prisms, which sublime at temperatures above 100° (192° ca.). Its most characteristic property is seen in its reaction with dilute acids, whereby water is separated and a compound isomeric with camphor formed. This reaction appears to indicate the existence of one ethylenic bond in camphene (G. Wagner, *B.* 23, 2307). Brühl (*B.* 25, 160) also finds, as the result of his latest determinations of the molecular refraction and dispersion of camphene, that this hydrocarbon contains one ethylenic linkage. Wallach (*B.* 24, 1555) upon other grounds appears to hold the same view. Camphene is, however, so closely connected with camphor that the constitution of the latter compound when settled may serve as a guide in determining the constitution of the former. The formula for camphor given by Kekulé (*B.* 6, 981) was based upon the supposed intimacy of its relation to cymene and carvacrol.

There can be no serious doubt of its character as a ketone, inasmuch as it yields an oxim, though it gives no compound with NaHSO_3 ; but the action of dehydrating agents upon camphor is very complicated, and there can be no doubt that the production of cymene is attended by isomeric change. Armstrong & Kipping (*C. J.*, Jan. 1898) have shown that among the products of the action of strong sulphuric acid upon camphor

there is a considerable quantity of acetyl-orthoxylylene ($\text{C}_2\text{H}_4\text{Me.Me.Ac}$, $\text{Me:Me:Ac} = 1:2:4$). From observation of its molecular refraction Brühl (*B.* 21, 467) suggests a formula containing a para-linkage, either

The former of these two formulae has also been used by Wallach (*B.* 24, 1555). These expressions are equivalent to representing camphor as a derivative of tetramethylene.

A formula of a different character has been suggested by Armstrong a. Miller (*B.* 16, 2260) (*v.* vol. i. p. 670), and another of somewhat similar type by Collie (*B.* 25, 1114):

Camphor by oxidation with nitric acid yields camphoric acid in large quantity, and as the characteristic and chief product. Camphoric acid is therefore probably derived from camphor by an operation of a simple kind without constitutional disturbance. The following formula proposed by Collie (*B.* 25, 1116) has been shown to possess a very high degree of probability (Walker, *C. J.*, April 1893):

This formula sufficiently accounts for the chief facts concerning camphoric acid, viz. that it is a saturated dibasic acid, which readily yields the anhydride by heating; that it is optically active, and when treated with hydrogen iodide yields tetrahydro- and hexahydro-*m*-xylene.

From this formula are deducible the following formulae for camphor and camphene:

This formula for camphene explains pretty well all its relations, except its derivation from pinene, if either of the formulae containing a para-linkage be adopted. The chief objections to such formulae are stated above.

J. Brett (*B.* 26, 3047) has recently proposed formulae for camphene, camphor, and camphoric acid, which are derived from a pentamethylene ring.

Synthesis of Terpenes.

Von Baeyer in a series of papers has shown that various dihydro-derivatives of benzene and its homologues may be synthetically produced. Starting with succino-succinic ester, this compound, by treatment with dilute sulphuric acid, yields diketo-hexamethylene, and this, by reduction with sodium-amalgam, gives the corresponding glycol. This glycol possesses the characters of a sugar, and has been named chinite or quinite (*B.* 25, 1037). It occurs in two isomeric forms, which by treatment with hydrogen bromide yield two dibromohexamethylenes. Both of these by heating with quinoline yield dihydrobenzene (*B.* 25, 1840), a liquid which has nearly the same boiling-point as benzene, but combines with HBr and with Br₂. It also reduces permanganate. By a corresponding series of processes dihydro-*p*-xylene was obtained from dimethylsuccino-succinic ester (*B.* 25, 2122). Dihydro-*p*-xylene (134° circa) smells of turpentine, unites with hydrogen bromide, but forms no crystallisable nitrosite.

In order to produce a dihydrocymene it is necessary to start from the methyl-propyl compound of succino-succinic ester. This compound was obtained by heating the sodium compound of the monopropryl ether with methyl iodide (*B.* 26, 253). Methyl-isopropryl-dihydrobenzene boils at about 174°. It smells like turpentine and resinifies in the air. It decolourises permanganate and unites with bromine, forming an uncrystallisable bromide. Although closely resembling a terpene, however, it is obvious that this hydrocarbon is not identical with any natural terpene known, containing, as it does, no asymmetric carbon. It may be identical with terpinene. The relations of the paradibromohexamethylene, or of its alkyl derivatives, to the corresponding hydrocarbon is shown in the following formulae (*B.* 25, 1840, 2122):

W. A. T.

TERPENYLIC ACID $\text{C}_{12}\text{H}_{18}\text{O}_2$. [72°] (Fittig); [58°] (Wallach). Formed, together with terebic acid, by oxidising oil of turpentine and other terpenes with chromic acid mixture (Hempel, *B.* 8, 857; *A.* 180, 77; Fittig a. Kraft, *A.* 208, 71). Formed also by oxidising pinol hydrate [131°] with KMnO_4 (Wallach, *A.* 259, 318). Monoclinic prisms (containing aq).

Reactions.—1. Yields acetic acid and CO_2 on

further oxidation by *chromic acid*.—2. On *dry distillation* it yields teracrylic acid (218°), a very little oxy-heptolactone (212°) and other bodies (Amthor, *J. pr.* [2] 42, 888).—3. Reduced by HI and P to β -isopropyl-glutaric acid (Schryver, *C. J.* 63, 1844).

Salts.—BaA'. Amorphous powder, v. e. sol. water. Converted by boiling with baryta into barium diaterpenylate $\text{Ba}(\text{C}_{10}\text{H}_{18}\text{O}_2)_2$ aq, which separates in needles on heating the cold saturated solution and is v. sl. sol. water. On adding an acid the liberated diaterpenylic acid at once changes to its lactone, terpenylic acid.—CuA', zaq.—AgA'. Crystalline mass. Silver diaterpenylate $\text{AgC}_{10}\text{H}_{18}\text{O}_2$ is ppd. by adding AgNO_3 to a solution of barium diaterpenylate.

Ethyl ether EtA'. [38°]. (305° i.v.). Monoclinic crystals; $a:b:c = 1.051:1.381$; $\beta = 50^\circ 58'$. V. sol. alcohol and ether, sl. sol. cold water. Sodium converts it into (a)- and (b)-diterpodilactone $\text{C}_{15}\text{H}_{22}\text{O}_8$.

(a)-Diterpodilactone $\text{C}_{15}\text{H}_{22}\text{O}_8$. [154°]. Formed as above (Fittig, *A.* 256, 113). Long needles (from water), m. sol. alcohol. Yields $\text{CaC}_{15}\text{H}_{24}\text{O}_8$, 6aq, $\text{Ag}_2\text{C}_{15}\text{H}_{24}\text{O}_8$, and $\text{BaC}_{15}\text{H}_{24}\text{O}_8$, 6aq crystallising in monoclinic prisms; $a:b:c = .935:1.595$; $\beta = 65^\circ 54'$, which, when decomposed by HCl and immediately extracted with ether yields (a)-diterpolactonic acid $\text{C}_{15}\text{H}_{24}\text{O}_8$ [160°]. This acid decomposes above 160° into water and its lactone.

(b)-Diterpodilactone $\text{C}_{15}\text{H}_{22}\text{O}_8$. [135°]. A product of the action of Na on terpenylic ether (Fittig, *A.* 256, 122). Needles, m. sol. alcohol. Converted by baryta into (b)-diterpolactonic acid [187°] and (b)-diterpoxylidic acid $\text{C}_{15}\text{H}_{20}\text{O}_8$. (b)-diterpolactonic acid forms trimetric crystals; $a:b:c = .782:1.259$ and is re-converted by heat into the lactone. (b)-Diterpoxylidic acid forms the salts BaA'' 3/4 aq, CaA'', and AgA''.

(a)-Diterpylic acid $\text{C}_{16}\text{H}_{22}\text{O}_9$. (a)-Diterpodilactone carboxylic acid. [216°]. An intermediate product of the action of Na on terpenylic ether. Needles, m. sol. alcohol. Converted by boiling HClAq or by heating above 216° into (a)-diterpodilactone.

TERPILENE v. TERPENES.

TERPILENOL $\text{C}_{10}\text{H}_{18}\text{O}$. [c. 32°]. (c. 130° at 50 mm.). S.G. c. .95. H.C. (inactive) 113, 318; (active) 102, 923 (Lougouine, *C. R.* 107, 1165). Got by saponification of the terpine acetates $\text{C}_{10}\text{H}_{17}\text{HOAc}$ or terpine formates $\text{C}_{10}\text{H}_{17}\text{CH}_2\text{O}_2$ by alcoholic potash (Lafont, *A. Ch.* [6] 15, 205). Crystals, insol. water, v. sol. oil of turpentine, alcohol, and ether. Boils with decomposition at 220°. Occurs in several forms varying in their action on polarised light.

Reactions.—1. HCl forms $\text{C}_{10}\text{H}_{17}\text{2HCl}$ [48°], which is inactive even if the terpinol were active.—2. Alcohol and HNO_3 give $\text{C}_{10}\text{H}_{22}\text{O}_8$ [104°].—3. *Phthalic anhydride* forms terpine $\text{C}_{10}\text{H}_{18}$.—4. Ac_2O at 100° forms the acetyl derivative or terpine acetate.

Acetyl derivative $\text{C}_{10}\text{H}_{17}\text{OAc}$ or $\text{C}_{10}\text{H}_{17}\text{HOAc}$. (220°). S.G. 2 .971. V.D. 6.6. Obtained by heating terpine with HOAc at 150°. Liquid (Bouchardat & Lafont, *C. R.* 102, 1555).

Formyl derivative $\text{C}_{10}\text{H}_{17}\text{OCHO}$. [α]_D = -69° 25'. S.G. 2 .999. Formed from oil of turpentine and cold formic acid (Lafont, *C. R.*

106, 140). By heating with water at 100° 65 p.a. of the ether is saponified.

TERPIN v. TERPENES.

TERPINEOL v. TERPENES.

TERPYLONIC ACID $\text{C}_{10}\text{H}_{14}\text{O}_4$. [185°]. A product of the oxidation of turpentine by chromic acid mixture (Schryver, *C. J.* 63, 1828). Needles, v. e. sol. water, m. sol. ether. Differs from camphoronic acid in electrical conductivity.

TETANINE v. PTOMAINES.

TETRADECANAPHTHENE $\text{C}_{14}\text{H}_{28}$. (241° cor.). S.G. 2 .839. Occurs in petroleum from Baku (Markownikoff & Ogloblin, *J. R.* 15, 339).

n-TETRADECANE $\text{C}_{14}\text{H}_{30}$. *Diheptyl*. [4.5°]. (253°). S.G. 4 .775; 1/2 .768. Formed by heat-myristic acid with HI and P (Krafft, *B.* 15, 1700). Got also by the action of Na on *n*-heptyl iodide (Krafft, *B.* 19, 2223; Sorabji, *C. J.* 47, 37).

Reference.—DI-BROMO-TETRADECANE.

TETRADECENOIC ACID $\text{C}_{14}\text{H}_{26}\text{O}_2$ *i.e.* $\text{C}_6\text{H}_{13}\text{CH}:\text{C}(\text{C}_6\text{H}_{11})\text{CO}_2\text{H}$. *Amylhexylacrylic acid*. Formed by the action of alcoholic potash on cenanthol (Perkin, *B.* 15, 2803; 16, 211). Liquid, boiling *in vacuo* at 275° to 280°.

TETRADECENOIC ALDEHYDE $\text{C}_{14}\text{H}_{26}\text{O}$ *i.e.* $\text{CH}_3(\text{CH}_2)_5\text{CH}:\text{C}(\text{CHO})(\text{CH}_2)_5\text{CH}_3$. (278°). S.G. 1/2 .849. Formed by the action of alcoholic potash or of ZnCl_2 on cenanthol (Perkin, *C. J.* 43, 47). Oil, not solid at -20°. Forms crystalline $\text{C}_{14}\text{H}_{26}\text{ONaHSO}_4$. Yields hexoic and heptoic acids on oxidation.

TETRADECENYL ALCOHOL $\text{C}_{14}\text{H}_{28}\text{O}$. (282°). S.G. 1/2 .852. Formed by reducing the preceding aldehyde with sodium-amalgam (Perkin, *B.* 15, 2808). It is also a product of the action of sodium-amalgam on a solution of cenanthol in HOAc (Perkin, *C. J.* 43, 68). Oil. May be reduced to $\text{C}_{14}\text{H}_{30}\text{O}$.

Acetyl derivative $\text{C}_{14}\text{H}_{27}\text{OAc}$. (285°-290°). S.G. 1/2 .868. Combines with Br (2 atoms).

TETRADECINENE $\text{C}_{14}\text{H}_{26}$ *i.e.* $\text{CMe}:\text{C.C}_{11}\text{H}_{23}$. [6.5°]. (184° at 15 mm.). S.G. 6/10 .8064; 15/2 .8000. Formed from tetradecylene bromide and alcoholic potash at 150° (Krafft, *B.* 17, 1872; 25, 2249).

TETRADECOIC ACID $\text{C}_{14}\text{H}_{28}\text{O}_2$ *i.e.* $\text{C}_6\text{H}_{11}\text{CH}(\text{C}_6\text{H}_{13})\text{CO}_2\text{H}$. (300°-310°). Got by the action of moist Ag_2O on the corresponding aldehyde (Perkin, *C. J.* 43, 74). Liquid, not solid at -10°.

Tetradecoic acid v. MYRISTIC ACID.

Reference.—OXYTETRADECOIC ACID.

TETRADECOIC ALDEHYDE $\text{C}_{14}\text{H}_{26}\text{O}$ *i.e.* $\text{C}_6\text{H}_{11}\text{CH}(\text{C}_6\text{H}_{13})\text{CHO}$. [80°]. (267°). S.G. 3/10 .827. A product of the action of Na on an ethereal solution of cenanthol (Perkin, *C. J.* 43, 71). Tables, v. sol. alcohol. Reduces ammoniacal AgNO_3 . Yields heptoic, hexoic, and acetic acids on oxidation.

Isomeride v. MYRISTIC ALDEHYDE.

n-TETRADECYL ALCOHOL $\text{C}_{14}\text{H}_{30}\text{O}$. [38°]. (167° at 15 mm.). S.G. 9/10 .8153. Formed by reducing myristic aldehyde (Krafft, *B.* 16, 1720).

Acetyl derivative $\text{C}_{14}\text{H}_{29}\text{OAc}$. [13°]. (176° at 15 mm.).

Tetradecyl alcohol $\text{C}_6\text{H}_{11}\text{CH}(\text{C}_6\text{H}_{13})\text{CH}_2\text{OH}$. (270°-275°). S.G. 1/2 .8368. Formed by reducing the corresponding aldehyde or the alde-

hyde $C_{11}H_{20}O$ (Perkin, *B.* 15, 2811; *C. J.* 43, 76). Liquid, solidifying at -10° .

Acetyl derivative $C_{11}H_{20}OAc$. (*c.* 278°). S.G. $1\frac{1}{2}$ ·856. Oil, not solid at -10° .

n-TETRADECYLENE $C_{14}H_{28}$ *i.e.* $CH_2:CH.C_2H_5$. [-12°]. (127° at 15 mm.) S.G. $\frac{2}{3}$ ·7852; $\frac{1}{2}$ ·7745. Formed by distilling tetradecyl palmitate at 500 mm. (Krafft, *B.* 16, 3021). Liquid.

Bromide v. Di-BROMO-TETRADECANE.

TETRADECYLENE GLYCOL v. Di-iso-BUTYL PINACONE.

TETRADECYL-MALONIC ACID $C_{17}H_{32}O_4$ *i.e.* $C_{14}H_{26}CH(CO_2H)_2$. [118°]. Formed by boiling its nitrile with alcoholic potash (Hell a. Jordanoff, *B.* 24, 988). White powder (from HOAc), insol. water, v. sl. sol. ether, sl. sol. cold alcohol. At 150° - 170° it is split up into CO_2 and palmitic acid.— Ag_2A' : white pp.

Amide $C_{14}H_{26}CH(CO_2H)(CONH_2)$. Pearly scales. At $c.$ 140° it yields palmitic amide.

Nitrile $C_{14}H_{26}CH(CO_2H).CN$. [76°]. Formed by heating *p*-bromo-palmitic ether with alcoholic KCy . Silky plates (from HOAc).

n-TETRA-ICOSANE $C_{24}H_{50}$. [51°]. (243° at 15 mm.). S.G. $\frac{7}{8}$ ·763; $\frac{9}{10}$ ·748. Formed by the action of HI and P on $C_{11}H_{23}CCl_2.C_6H_5$, made from the ketone obtained by distilling barium stearate with barium heptoate (Krafft, *B.* 15, 1718).

TETRA-ICOSOIC ACID $C_{22}H_{42}.CO_2H$. [$72\text{--}5^{\circ}$]. Occurs in the soap got by heating carnauba wax with aqueous $NaOH$ (Stärcke, *A.* 223, 307). Crystalline powder, v. sol. hot alcohol.— PbA_2 . [111°]. Sol. toluene and hot HOAc.

TETRAZOLE $N \begin{smallmatrix} \diagup N \\ \diagdown CH.NH \end{smallmatrix}$. [155°]. Formed by treating amido-phenyl-tetrazole carboxylic acid with alkaline $KMnO_4$, followed by HNO_3 (Bladin, *B.* 25, 1412). Plates (from toluene). Reddens blue litmus.

TETRAZYL-HYDRAZINENH₂.NH.C $\begin{smallmatrix} N-N \\ \diagup NH.N \end{smallmatrix}$. [199°]. Formed from amido-tetrazotic acid by diazotisation and reduction by $SnCl_2$ (Thiele, *A.* 273, 155). Yellowish crystalline aggregates, v. sol. hot water.— $B''2HCl$. [176°]. Acetoacetic ether forms $\begin{smallmatrix} CH.CO \\ CMe.NH \end{smallmatrix} > N.C \begin{smallmatrix} N-N \\ \diagup NH.N \end{smallmatrix}$ [215°] crystallising in needles.

TETRIC ACID $C_{10}H_{12}O_4$ *i.e.* $CH_2:C(OH).CMe \begin{smallmatrix} O \\ \diagdown CO \end{smallmatrix} > CMe.C(OH):CH_2$

(Nef, *A.* 266, 92) or $CH_2.CO.C(CO_2H):CH_2$. **Acetyl-acrylic acid**. [189°]. (262°). S. 1·5 at 14° . **Electrical conductivity**: Walden, *B.* 24, 2027. Got by heating $CH_3.CO.CMe.Br.CO_2Et$ at 100° , but not by heating the isomeric acid $CH_2.Br.CO.CHMe.CO_2Et$ (Nef; *cf.* Pawloff, *B.* 16, 486). Formed by successive action of bromine and alcoholic potash on methyl-acetoacetic ether (Demarçay, *C. R.* 87, 351; 88, 126). Triclinic prisms (from water), v. sol. hot water, alcohol, and ether. Gives a violet-red colour with $FeCl_3$. PCl_5 gives rise to several compounds boiling between 160° and 185° which take up chlorine forming $C_5H_7Cl_3O$ (Pawloff, *Bl.* [2] 45, 181; *C. R.* 97, 99). Demarçay obtained oily $C_5H_7Cl_3O$ (?) which united with Cl and Br forming $C_5H_7Cl_4O$ [48°] and $C_5H_7Cl_5Br_2O$ [67°]. Resinified by dilute $HClAq$ at 150° . Potash-

fusion gives formic and propionic acids. Distillation with lime forms methyl ethyl ketone. Sodium-amalgam has no action.

Salts.— $(NH_4)_2A''$. Crystals, v. sol. water.— NaA' 6aq.— K_2A'' .— BaA'' 3aq. Needles, v. e. sol. water.— BaA'' 2aq.— $Ba_2(OH)_2A''$. Sl. sol. water.— CaA' 2aq.— MgA'' 10aq.— ZnA'' aq.— CuA'' .— Ag_2A'' . Needles, sl. sol. water.

Ethyl ether $\begin{smallmatrix} CMe:C(OEt) \\ CO-CH_2 \end{smallmatrix} > O$ (?). [30°].

(180° at 70 mm.) (Moscheles, *B.* 21, 2607).

Amide $C_8H_{13}NO_2$. [212°]. Got by heating the acid with alcoholic NH_3 .

TETROLE CYANURAMIDE v. Nitrile of PYRROLE CARBOXYLIC ACID.

TETROLIC ACID $C_6H_8O_4$ *i.e.* $CH_3.C:C.CO_2H$. **Butyrollic acid**. Mol. w. 84. [77°]. (203°). Formed by boiling β -chloro-crotonic acid or β -chloro-iso-crotonic acid with dilute potash (Geuther, *Z.* 1871, 245; Friedrich, *A.* 219, 843; Kahlbaum, *B.* 12, 2338). Formed also by the action of Na and CO_2 on allylene chloride (Pinner, *B.* 14, 1081).

Preparation.—From acetoacetic ether and PCl_5 , the product being freed from $POCl_3$ by heating to 115° , mixed with water, and freed from chloro-crotonic acid by distillation with steam. The residue is treated with alcoholic potash (Fittig a. Clutterbuck, *A.* 268, 96; *cf.* Friedrich, *A.* 219, 322).

Properties.—Plates (from ligroin). May be sublimed. V. e. sol. water, alcohol, and ether. Not reduced by sodium-amalgam to crotonic acid (*F. a. C.*; *cf.* Aronstein, *B.* 22, 1181). Slightly volatile with steam.

Reactions.—1. Br forms di-bromo-crotonic acid [120°], which is reduced by sodium-amalgam to tetrollic acid. **Bromine** also yields $C_4H_5Br_2O_2$. [97°] (Pinner).—2. HBr forms bromo-crotonic acid [91°].—3. Heated with conc. KOH aq it forms acetone.—4. Fuming $HClAq$ at 15° in a few weeks converts it into β -chloro-crotonic acid [$94\text{--}5^{\circ}$].—5. Boiling with Na and $MeOH$ yields butyric acid (*A.*).—6. **Chlorine** forms $C_4H_5Cl_3O_2$. 7. On heating with **iodine** in $CHCl_3$ in sealed tubes it yields di-iodo-crotonic acid (*B.* 26, 843).—8. Split up at 211° into CO_2 and allylene.—9. $KMnO_4$ forms acetic acid.

Salts.— NaA' . Crystalline.— KA' (dried at 100°). Prisms (from alcohol).— NH_4A' .— LiA' aq.— MgA' 3aq.— BaA' 3aq.— CaA' 3aq. Small needles.— ZnA' 2aq (Lagermark, *J. R.* 12, 290).— ZnA' 2aq (Fittig). Groups of prisms.— CdA' 4aq.— PbA' 2aq. S. 1·5 in 92 p.c. alcohol at 20° .

Chloride C_4H_5OCl . Fuming liquid, carbonised by heat. Quickly decomposed by water (Lagermark, *Bl.* [2] 35, 171).

DI-TETROLUREA v. CARBONYL-PYRROL.
TETROLE-URETHANE v. Ethyl ethyl of PYRROLE CARBOXYLIC ACID.

TEUCRIN $C_{24}H_{40}O_{11}$ or $C_{24}H_{40}O_{11}$. [230°]. A glucoside occurring in *Teucrium fruticans*, a plant used in Sicily as febrifuge. Extracted by alcohol (Ogialoro, *G.* 9, 440; 13, 493). Slender yellow prisms. Boiling dilute nitric acid forms anisic, tartaric, and oxalic acids. Boiling dilute H_2SO_4 yields glucose and a yellow insoluble residue.

TEWFIKOSE. $[a]_D = 53\text{--}1^{\circ}$. A sugar occurring in the milk of the Egyptian buffalo (*Box* X X

bulbus). Yields glucose on hydrolysis (Pappel a. Richmond, *C. J.* 57, 759), v. Sugars.

THALICTRINE. *Macrocarpine*. Occurs in *Thalictrum macrocarpum* (Hanriot a. Doassans, *Bl.* [2] 34, 83). Yellow needles, insol. water, sol. alcohol and ether. Resembles aconitine, but is less poisonous.

THALLIN v. OXY-QUINOLINE.

THALLIUM. Tl. At. w. 203.64. Mol. w. 407.28 as gas at c. 1700° (*v. infra*). Melts at 293.9° (Crookes, *C. J.* 17, 123; cf. Lamy, *A. Ch.* [3] 67, 385). Boils at full red heat. S.G. pressed 11.88, cast 11.81, in wire 11.91 (Crookes, *l.c.*; cf. Lamy, *l.c.*; Werther, *J. pr.* 91, 385; de la Rive, *C. R.* 56, 588). V.D. 232.7 at 1636°, 203.7 at 1728° (Biltz a. V. Meyer, *B.* 22, 725). S.H. .0325 (Lamy, *l.c.*); .0335 (17°–100°) (Regnault, *A. Ch.* [3] 67, 437). C.E. (linear) .00003021 at 40°, .00003135 at 50° (Fizeau, *C. R.* 68, 1125). E.C. 5.225 at 0° (Hg at 0° = 1) (Benoit, *P. M.* [4] 45, 314; cf. Matthiessen, *P.* 118, 431). H.C. [Tl₂O] = 42,240 (*Th.* 3, 354). Latent heat of fusion c. 1040 for 203.6 g. (Heycock a. Neville, *C. J.* 65, 35). The characteristic green line of the emission spectrum has the wave-length 5347 according to Huggins (*T.* 1864, 139), 5349.6 according to Mascart (*Ann. de l'écol. norm.*, 4, 7 [1867]), and 5349.5 according to Thalen (*Détermin. des long. d'onde des raies métalliques* [Upsala, 1868]). Concerning the emission spectrum of Tl v. also Crookes, *Pr.* 12, 536; Nicklès, *C. R.* 58, 132; Kirchhoff a. Bunsen, *A.* 155, 230, 366; Lockyer a. Roberts, *Pr.* 23, 344; Liveing a. Dewar, *Pr.* 27, 132; Hartley a. Adeney, *T.* 1884, 104; Becquerel, *C. R.* 99, 376; Wilde, *Pr.* 53, 369.

Historical.—In 1861 Crookes was preparing Se from the flue-dust of a sulphuric acid manufactory at Tinkelrode in the Harz mountains, when on distilling the impure Se he obtained a residue which showed a marked single green line in the spectrum; this line was not known to belong to the spectrum of any element, hence Crookes supposed that the impure Se contained a new element. Crookes isolated the element towards the end of 1861, and called it thallium (from *θαλλός* = a green bud) (*v. C. N.* 3, 193, 303). Lamy (*A. Ch.* [3] 67, 385) noticed a new green line in the spectrum of a leaden chamber deposit about the same time as Crookes was investigating the cause of the line he had observed; in 1862 Lamy isolated a specimen of the metal which Crookes had obtained a few months before.

Occurrence.—Never uncombined. Compounds of Tl are widely distributed, but only in very small quantities. The sulphide occurs in minute quantities in many specimens of *copper pyrites* and *iron pyrites* (*v. Crookes, C. J.* 17, 112; Lamy, *l.c.*; Wöhler, *A.* 142, 263; Carstén, *J. pr.* 102, 65; Gunning, *Tr. N.* 8, 86); also in native sulphur from Lipari and Spain. Compounds of Tl are found in small quantities in many ores of As, Bi and Hg, and in preparations from these ores; also in commercial Se and Te, probably as selenide and telluride (*v. Crookes, l.c.*; Röppler, *Am. S.* [2] 35, 420; Hera-path, *Ph.* 4, 302; Werther, *J. pr.* 89, 129). Some specimens of *lepidolite* contain small quantities of Tl compounds (*v. Schrötter, W. A. B.* 48 (ii.) 734; 50 (ii.) 268). A Swedish

mineral called *crookesite* was found by Norden-skjöld to contain from 16.3 to 18.55 p.c. Tl as selenide, along with selenides of Cu and Ag (*Bl.* [2] 7, 409). Small quantities of TlCl are found in some mineral springs and in the saline deposits from such springs (*v. Böttger, J. pr.* 89, 378; 90, 22; 96, 294). Traces of Tl alum have been found accompanying the double sulphates of Cs, Li, and Rb in *alumite* from the island of Volcano (Cossa, *Acad. dei Lincei* [3] 2). Small quantities of Tl compounds have been noticed in *carnallite*, *syilvine*, and *kainite* (Schramm, *A.* 219, 374). Many specimens of commercial sulphuric and hydrochloric acids contain traces of Tl compounds (*v. Crookes, l.c.*).

Formation.—(Crookes, *l.c.*; or *T.* 1872.)—1. By reducing Tl₂CO₃ by fusion with KCN.—2. By electrolysis of Tl₂CO₃ covered with water.—3. By electrolysis of Tl₂SO₄.—4. By heating Tl₂C₂O₄ in a covered crucible.—5. By ppg. by zinc from solution of a thallous salt to which excess of NH₄Aq or NaOHaq has been added.

Preparation.—The most economical source is the flue-dust from sulphuric acid manufactories where pyrites or sulphur containing Tl compounds has been used. Many specimens of flue-dust contain no Tl compounds; in some specimens 8 p.c. Tl has been found, but only in a very few does the quantity amount to .25 p.c. Tl (Crookes). After having been heated to dull redness, to remove any HCl, the dust is well stirred in wooden tubs with its own weight of boiling water and allowed to settle for 12 hours; the liquid is siphoned off, and the residue is again stirred with boiling water and let settle; the mixed liquids are ppd. by a considerable excess of conc. HClaq; the pp., which is crude TlCl, is well washed on a calico filter and squeezed dry. About 68 lbs. crude TlCl were thus obtained from 3 tons flue-dust (Crookes, *T.* 1872). The crude TlCl is heated with its own weight of pure conc. H₂SO₄ in a Pt dish till all HCl and most of the H₂SO₄ are removed; the TlHSO₄ is dissolved in c. 20 times its weight of water, the solution is nearly neutralised by CaCO₃, filtered, ppd. by conc. HClaq, and the TlCl so obtained is well washed, and is then boiled for a few minutes with (NH₄)₂SAq; the pp. of Tl₂S is filtered off, well washed with water containing H₂S, and dissolved in dilute H₂SO₄aq; the solution is boiled to remove H₂S, ammonia is added in slight excess, and after boiling the solution is filtered and crystallised; (NH₄)₂SO₄, being much more soluble in water than Tl₂SO₄, remains in solution when Tl₂SO₄ crystallises out.

If small quantities of Tl are to be prepared from Tl₂SO₄, the salt is dissolved in c. 20 times its weight of water, the solution is acidulated with H₂SO₄, and electrolysed, Pt electrodes being used. If large quantities of Tl are to be prepared, Tl₂SO₄ is placed in a deep porcelain dish (holding about 4½ litres) and covered with water (c. 3 kilos Tl₂SO₄ are used at a time) and plates of pure zinc are arranged vertically around the sides of the vessel; heat is applied, and the whole of the Tl separates in a few hours as a spongy mass easily detached from the zinc by shaking. The spongy Tl is washed several times, pressed by the fingers, and then fused with KCy in a porcelain crucible to get it into a

lump (for details *v.* Crookes, *l.c.*; *v.* also Gunning, *J. pr.* 105, 843).

Crookes (*l.c.*) gives several methods for preparing pure Tl. If the starting-point is commercial Tl_2SO_4 , he recommends to dissolve this salt in water, to saturate the cold solution with pure H_2S , filter, heat to boiling, and pour into boiling, dilute, pure $HClAq$; to filter while hot, and allow to cool; to wash the $TlCl$ that crystallises out, by decantation, till the washings are free from H_2SO_4 , and to purify by re-crystallising twice, from water. The $TlCl$ thus obtained is dried, mixed with pure Na_2CO_3 , and projected, in small successive portions, into molten pure KCy in an unglazed porcelain crucible; reduction to metal is rapid. After cooling, the contents of the crucible are treated with water, the ingot of Tl is boiled for some time in water, dried, and fused over a spirit lamp (coal-gas should not be used on account of the S compounds in it) in an unglazed porcelain crucible, with free access of air and frequent stirring with a piece of unglazed porcelain, to facilitate oxidation, and the metal is poured into a porcelain mould.

Properties.—A white metal without any tinge of blue; when fused under coal-gas, liquid Tl is exactly like Hg; may be highly polished by rubbing under water; very soft, may be cut with the nail, or scratched by lead. Less tenacious than lead; does not become brittle between -18° and its m.p.; very malleable, Lamy (*A. Ch.* [3] 67, 385) says that plates $\frac{1}{15,000}$ mm. thick

can be obtained; can be squeezed, but not drawn, into wire; very inelastic. Tl crystallises very easily in octahedral forms; it crackles like tin when bent; a wire of Tl seems amorphous when prepared, but under water it soon becomes crystalline. Tl quickly tarnishes in air; the film of oxide formed protects the mass of metal. The metal may be kept unchanged for years under water that has been deprived of air (*v.* Böttger, *D. P. J.* 197, 374). Tl melts easily (at 294°) without first becoming pasty; it expands considerably before melting is complete, and contracts much on cooling. Tl boils below white heat; it may be distilled in a current of H. Pieces of the metal may be welded together by pressure at the ordinary temperature. Tl is nearly as diamagnetic as bismuth. Tl gives an intense green colour to a non-luminous flame (*v. infra, Detection*). Heated in air, Tl readily burns to Tl_2O ; it combines with S, Se, P, Cl, Br, I, &c., when heated with these elements; it dissolves in solutions of most acids (*v. Reactions*). The compounds of Tl are very poisonous, producing symptoms like those of lead poisoning.

The at. w. of Tl has been determined (1) by ppg. Cl as $AgCl$ from $TlCl$ by $AgNO_3Aq$ (Lamy, *A. Ch.* [3] 67, 385 [1862]; Heberling, *A.* 134, 11 [1865]); (2) by ppg. I from TlI by $AgNO_3$ (Werther, *J. pr.* 92, 136 [1864]); (3) by converting Tl_2SO_4 into $BaSO_4$ (Lamy, *l.c.*; Heberling, *l.c.*); (4) by converting Tl into $TlNO_3$ (Crookes, *T.* 1873. 277); (5) by determining S.H. of Tl (Lamy, *l.c.*; Regnault, *A. Ch.* [3] 67, 437 [1862]); (6) by determining V.D. of $TlCl$ (Roscoe, *Pr.* 27, 426).

The mol. w. of Tl in the gaseous state is double the at. w.; in other words, the gaseous

molecule is diatomic (Biltz & Meyer, *B.* 22, 725). Ramsay (*C. J.* 55, 521) determined the depression produced in the vapour pressure of Hg by dissolving Tl in that solvent; assuming that equal volumes of dilute solutions contain equal numbers of molecules, and that the mol. w. of liquid Hg is 200, the results obtained by R. indicated the molecule of Tl dissolved in Hg to be monatomic.

Tl is distinctly a metallic element; no compounds have been isolated wherein Tl certainly forms part of the negative radicle, although there are indications of the existence of such compounds (*v.* THALLIUM DIOXIDE, p. 680); the compounds which $TlBr_3$, $TlCl_3$, and TlI_3 form with alkali halides may contain Tl in the negative radicles. Tl is the last element in the odd-series family of Group III.; this family comprises Al, Ga, In, and Tl. The element Tl also shows marked resemblances to the alkali metals; and in its physical properties it is more like lead than any other element. The position assigned to Tl by the periodic classification of the elements clearly indicates the relations between this element and other elements. The relations of Tl (III.-11) to Al (III.-3) should be similar to those of Hg (II.-11) to Mg (II.-3), and also similar to those between Pb (IV.-11) and Si (IV.-3). The resemblances between the compositions and properties of the oxides of Hg and Mg on the one hand, and of the oxides of Pb and Si on the other hand, are shown only in the highest oxides of these elements: there is Hg_2O but no Mg_2O , there is PbO but no SiO ; HgO and MgO are basic, PbO , and SiO_2 are feebly acidic. Nevertheless Hg and Pb form lower oxides than HgO and PbO_2 ; these lower oxides, Hg_2O and PbO , are basic; Hg_2O feebly, and PbO strongly, basic. Hence it is likely that the resemblances between the oxides of Tl and Al will be shown in the highest oxides. This supposition is confirmed; Tl_2O_3 and Al_2O_3 are basic, forming salts M_2X_2 , where X = the radicle of a dibasic acid; these oxides are more basic than PbO_2 and SiO_2 , but less basic than HgO and MgO . As Hg and Pb form lower oxides than HgO and PbO_2 , and these lower oxides are more basic than HgO and PbO_2 , so Tl will likely form an oxide lower than Tl_2O_3 , and this oxide will be more basic than Tl_2O_3 ; Tl forms the strongly basic oxide Tl_2O . Then consider the position of Tl in series 11. Consider the oxides of the members of this series: the lower oxides Hg_2O , PbO , and Bi_2O_3 are basic; the higher oxides HgO , PbO_2 , and Bi_2O_5 pass from basic (HgO) to feebly acidic (PbO_2 and Bi_2O_5); therefore it is probable that the higher oxide of Tl will be less basic than HgO , but that it will not be acidic; Tl_2O_3 is a feebly basic oxide.

If the chlorides of series 11 are considered, the position of Tl in III.-11 is seen to be justified: $HgCl_2$ gives $HgCl$, which can be gasified unchanged, PbO_2 gives $PbCl_2$, which is very easily decomposed by heat, no chloride corresponding with Bi_2O_5 has been isolated; therefore Tl_2O_3 will probably give a chloride more stable towards heat than $PbCl_2$, but less stable than $HgCl_2$. $TlCl_3$ is decomposed by heating to $c. 80^\circ$ into $TlCl$ and Cl. Hg_2O gives $HgCl$, PbO gives $PbCl_2$, and Bi_2O_5 gives $BiCl_3$, and these chlorides can all be gasified unchanged; there-

fore the chloride of Tl corresponding with Tl_2O will probably not be decomposed by heat; $TlCl$ has been gasified unchanged. The relations between the elements Hg, Tl, Pb, Bi, and Mg, Al, Si may be summarised in the expressions $Tl : Hg : Pb : Al : Mg : Si$; and $Tl : Hg : Pb : Tl : Bi : Pb$. (For a further working out of the relations of Tl, v. Mendeléeff, *C. N.* 1880, 2; v. also ALKALIS, METALS OF THE, vol. i. p. 114; and EARTHS, METALS OF THE, vol. ii. p. 424.) The atom of Tl is monovalent in the gaseous molecule $TlCl$; the V.D. of no other compound of Tl has been determined.

Reactions and Combinations.—1. Exposed to air or oxygen, a film of Tl_2O is at once formed; when heated in air or O to somewhat below redness (c. 300°) Tl burns to Tl_2O_3 , and at a higher temperature this gives Tl_2O and O (Lamy, *A. Ch.* [3] 67, 385). Moist ozone acts on Tl giving TlO_3H_3 .—2. A compact piece of Tl does not decompose boiling water, decomposition begins at a red heat; but spongy Tl, as ppd. by zinc, dissolves in water forming $TlOHAq$.—3. Tl dissolves in solutions of most acids, forming thallous salts TlX , where $X = 2Cl, 2NO_3, SO_4$, &c.—4. Tl combines with sulphur and selenium (v. sulphides and selenides).—5. Forms alloys with many metals (v. alloys).—6. Forms compounds with antimony and arsenic (v. antimonide and arsenide).—7. A phosphide is formed by heating Tl in vapour of phosphorus (v. phosphide).—8. Combines with chlorine, bromine, and iodine, when heated with these elements (v. chlorides, bromides, and iodides).—9. Tl ppts. the noble metals, also copper, lead, and mercury from solutions of salts of these metals (Reid, *C. N.* 12, 242).

Detection and Estimation.—Tl is best detected by the intense green colour which the metal and its compounds give to the non-luminous flame of the Bunsen lamp; according to Lamy (*l.c.*) $\frac{1}{50,000}$ mgm. can be detected by the use of the spectroscope; if induction sparks are used it is said that $\frac{1}{50,000,000}$ mgm. can be detected (Cappel, *P.* 139, 628). Tl is generally estimated as TlI or Tl_2SO_4 ; it can also be determined volumetrically by $KMnO_4Aq$ (Willm, *Z.* 1863, 479).

Thallium, alloys of. Several alloys of Tl were prepared by Carstanjen in 1867 (*J. pr.* 102, 82) by heating the metals together. Many of the alloys are soft, and most of them readily tarnish in the air; the alloy with $\frac{1}{2}$ pt. Sb is fairly hard; and those with Bi and Pb, Bi and Cd, and Bi and Sn are hard and brittle. Alloys are described with Al, Sb, Cd, Cu, Pb, Mg (v. also Mellor, *C. N.* 19, 245), Hg (v. also Crookes, *l.c.*, and Regnault, *C. R.* 64, 60), K, Na, and Zn; also with Bi and Cd, Bi and Pb, and Bi and Sn.

Thallium, antimonide of. A hard, grey, crystalline solid was obtained by fusing together Tl and Sb in the ratio Tl : Sb; with cold dilute H_2SO_4Aq the substance gave off SbH_3 (Carstanjen, *l.c.*).

Thallium, arsenide of. Carstanjen (*l.c.*) obtained a white, crystalline, soft substance by fusing Tl and As in the ratio Tl : As; with cold acids AsH_3 was formed.

Thallium, bromides of. The compounds $TlBr$ and $TlBr_3$ have been isolated, and also two compounds the simplest formulae of which are

Tl_2Br_3 and $TlBr_3$. As none of the bromides has been gasified, the formulae are not necessarily molecular; but from the analogy of $TlCl$, the formula $TlBr$ probably represents the composition of the gaseous molecule of this compound.

Thallous bromide $TlBr$. (*Thallium monobromide*.) Tl reacts very slowly with Br. Thallous bromide is obtained, as a white pp., by adding $HBrAq$ or solution of a bromide to solution of a thallous salt; almost insoluble in water (Willm, *A. Ch.* [4] 5, 28). $TlBr$ melts at 458° to a brownish-yellow liquid, which solidifies to a yellow solid (Carnelley, *C. J.* 33, 278). Thomsen gives H.F. $[Tl, Br] = 41,290$ (*Th.* 3, 354).

Thallic bromide $TlBr_3$. (*Thallium tribromide*.) Prepared by adding Br to $TlBr$ suspended in water until solution is effected, and evaporating *in vacuo*. $TlBr_3$ forms a yellow, crystalline solid; it is very deliquescent, becoming gradually brown and giving off Br. Very soluble in water, also in alcohol. Reduced to $TlBr$ by SO_2Aq and other reducing agents (Willm, *l.c.*). Thomsen gives H.F. $[Tl, Br, Aq] = 56,450$ (*Th.* 3, 354). $TlBr_3$ combines with NH_3 to form $TlBr_3 \cdot 3NH_3$; a white solid that gives off NH_3 and Br at 100° , and when more strongly heated leaves $TlBr$ (W., *l.c.*). Also combines with NH_4Br and KBr , forming $TlBr_3 \cdot NH_4Br$ and $TlBr_3 \cdot KBr \cdot 2aq$ (W., *l.c.*; Nicklès, *C. R.* 58, 537). Rammelsberg (*P.* 146, 697) described $2TlBr_3 \cdot 3KBr \cdot 3aq$.

Thallium dibromide $TlBr_2$ (or $TlBr \cdot TlBr_3 = Tl_2Br_4$). Obtained in long, yellow, needles by adding $TlBr$ to boiling $TlBr_3Aq$, in the ratio $TlBr : TlBr_3$, and cooling. Not decomposed at 100° ; water forms $TlBr_3Aq$ and Tl_2Br_3 (v. *infra*) (W., *l.c.*).

Thallium sesquibromide Tl_3Br_5 , or $TlBr_3 \cdot 3TlBr = Tl_4Br_9$. (*Thallo-thallic bromide*.) Orange-red hexagonal leaflets; obtained by adding $HBrAq$ to a mixture of a thallous and a thallic salt in solution; also by adding $TlBr$ to $TlBr_3Aq$, or by adding a little water to $TlBr_3$ ($3TlBr_3 + Aq = Tl_4Br_9 + TlBr_3Aq$) (W., *l.c.*).

Thallium, chlorides of. Tl and Cl combine to form at least four compounds: $TlCl$, Tl_2Cl_3 , $TlCl_2$, and $TlCl_3$.

Thallous chloride $TlCl$. Mol. w. 239.01. Melts at 427° (Carnelley, *C. J.* 33, 277). Boils at 708° – 719° (C. A. Williams, *C. J.* 33, 284). S.G. 7.02, after fusion (Lamy, *J.* 15, 184). V.D. at 830° to $1025^\circ = 117.8$ (Roscoe, *Pr.* 27, 426). S. .19 at 0° , .27 at 16° , .28 at 16.5° , 1.6 at 63° (Heberling, *A.* 134, 15). H.F. $[Tl, Cl] = 48,580$; $[Tl, Cl, Aq] = 38,480$ (*Th.* 3, 354).

Formation.—1. By heating Tl in Cl, keeping the Tl in excess.—2. By boiling powdered Tl in $HClAq$, and dissolving the film of $TlCl$ that forms in much boiling water.—3. By adding SO_2Aq to $TlCl_3Aq$.

Preparation.— $HClAq$, or solution of a chloride, is added to the solution of a thallous salt; the white curdy pp. that forms is washed with cold water, dissolved in a large quantity of boiling water, and the salt that separates as the solution cools is purified by two or three recrystallisations from boiling water (Crookes, *C. J.* 17, 112).

Properties and Reactions.—A white, crystalline solid; resembling $PbCl_2$, but separating from solution in hot water in smaller and less shining crystals than $PbCl_2$. Becomes slowly

violet coloured when exposed to light (Hebberling, *A.* 134, 15). Melts at 427° to a clear yellow liquid, which solidifies to a white crystalline mass. Very slightly soluble in water (*v. supra*); less soluble in water containing a little HCl; insoluble in alcohol; insoluble in ammonia; soluble in hot $\text{Na}_2\text{CO}_3\text{Aq}$, KOH Aq , or $\text{Na}_2\text{SO}_4\text{Aq}$. Hot conc. sulphuric acid forms Ti_2SO_4 and HCl; oxidisers such as ClAq , *aqua regia*, KMnO_4Aq and HClAq , form TiCl_4 , Ti_2Cl_6 , or TiCl_3 (*v.* these chlorides). TiCl is reduced to Ti by zinc and sulphuric acid, also by adding aluminium to TiClAq at 90° (Cossa, *Acad. dei Lincei* [3] 2). Fusion with sodium hydrogen sulphate produces Ti_2SO_4 (Krause, *D. P. J.* 217, 323; Nietzki, *D. P. J.* 219, 262).

Combinations.—1. With *platinic chloride* to form $2\text{TiCl}.\text{PtCl}_4$ ($=\text{Ti}_2\text{PtCl}_6$); obtained, as a pale-yellow, crystalline powder, by mixing solutions of TiCl and PtCl_4 ; this salt is extremely insoluble in water, one part dissolving in 15,585 parts water at 15° , and in 1948 parts boiling water (Crookes, *l.c.*).—2. With *mercuric chloride*, to form TiCl.HgCl_2 ; white lustrous needles, separating from a hot solution of TiCl in HgCl_2Aq ; all HgCl_2 is removed at 200° (Carstanjen, *J. pr.* 102, 141; Jörgensen, *J. pr.* [2] 6, 82).—3. With *feric chloride* to form 3TiCl.FeCl_3 ; small red prisms; obtained by adding TiCl to a hot solution of FeCl_3 in HClAq , and crystallising the red pp. from hot conc. HClAq ; decomposed to its constituent salts by water (Wöhler, *A.* 144, 350).—4. With *chromic chloride*, to form 3TiCl.CrCl_3 (*v.* Neumann, *A.* 244, 328).—5. According to Lepierre a. Lachaud (*C. R.* 113, 196), a conc. solution of *chromium trioxide* reacts with TiCl to form small red prisms of $\text{CrO}_3.\text{TiCl}$ [$\text{CrO}(\text{OTi})\text{Cl}$], which are decomposed by water to TiCl and CrO_3Aq .

THALLIC CHLORIDE TiCl_3 . Mol. w. not certainly known; from analogy of AlCl_3 , GaCl_3 , and InCl_3 , the formula TiCl_3 is probably molecular.

Formation.—1. By heating TiCl with hot *aqua regia* and evaporating the solution in Cl (Willm, *A. Ch.* [4] 5, 28).—2. By dissolving freshly ppd. TiO_2H_2 in HClAq , adding HNO_3Aq , and evaporating in Cl .—3. By heating TiCl at its melting-point in Cl ; it is doubtful whether the product is pure TiCl_3 , or contains also TiCl_2 or Ti_2Cl_6 (Lamy, *l.c.*).

Preparation.— Cl is passed into water containing TiCl in suspension until a little of the solution ceases to give a turbidity with PtCl_4Aq ; excess of Cl is removed by a stream of CO_2 , and the solution is evaporated *in vacuo*. Crystals of $\text{TiCl}_3.\text{H}_2\text{O}$ separate, which lose water at $c. 40^{\circ}$ (Werther, *J. pr.* 91, 385).

Properties and Reactions.—The hydrate forms large colourless prisms; the dehydrated salt is a white crystalline solid. Werther (*l.c.*) also obtained a hydrate $2\text{TiCl}_3.15\text{H}_2\text{O}$ from a solution of TiCl_3 prepared as described. Cl begins to be given off at $c. 50^{\circ}$ to 60° ; at 100° a mixture of TiCl and chlorides intermediate between TiCl and TiCl_3 remains (Werther, *l.c.*; Lamy, *l.c.*). TiCl_3 is very deliquescent; it dissolves very easily in water. Thomsen gives $[\text{TiCl}_3.\text{Aq}] = 89,250$ (*Zh.* 3, 354). On diluting a conc. aqueous solution considerable quantities of TiO_2H_2 and HClAq are formed. Reducing agents, such as SO_2 , form TiCl .

Combinations.—1. With *ammonia* to form $\text{TiCl}_3.3\text{NH}_3$ (Willm, *A. Ch.* [4] 5, 28). A white, crystalline powder. Obtained by passing NH_3 over TiCl_3 ; by adding an alcoholic solution of NH_3 to TiCl_3 suspended in absolute alcohol; or by boiling TiO_2H_2 with conc. NH_3ClAq , ppg. by NH_3Aq , washing with alcoholic ammonia, then with absolute alcohol, and drying *in vacuo*. The compound is unchanged in air; water forms NH_3ClAq and Ti_2O_3 ; when heated NH_3 , NH_4Cl , and N are given off and TiCl remains. Dissolves in HClAq , forming $\text{TiCl}_3.3\text{NH}_4\text{Cl}$.—2. With *ammonium chloride* to form $\text{TiCl}_3.3\text{NH}_4\text{Cl}$; obtained by adding NH_4Cl to a solution of TiO_2H_2 in HClAq , and evaporating *in vacuo*; large, white, quadratic crystals, probably with $2\text{H}_2\text{O}$ (Rammelsberg, *P.* 146, 597; *v.* also Nicklès, *J. Ph.* [4] 1, 25).—3. Compounds with *potassium chloride*, *caesium chloride*, and *rubidium chloride*, $\text{TiCl}_3.3\text{MCl}$, zaq , have been obtained (*v.* Rammelsberg, *l.c.*, also *W.* 16, 709; Godeffroy, *Zeit. des allgemein. österr. Apotheker-Ver.* 1880. No. 9; Neumann, *A.* 244, 348; Willm, *l.c.*). Neumann (*l.c.*) also describes a compound of TiCl_3 with *beryllium chloride*.—4. Willm (*l.c.*) describes a compound with *cupric chloride*, $2\text{TiCl}_3.\text{CuCl}_2$.—5. According to Nicklès (*C. R.* 58, 537) TiCl_3 forms a compound with *ether and hydrochloric acid*, to which he gives the composition $\text{TiCl}_3.\text{Et}_2\text{O.HCl.H}_2\text{O}$; it is described as a yellow fuming liquid.

THALLIUM DICHLORIDE TiCl_2 (or $\text{TiCl}.\text{TiCl}_2 = \text{Ti}_2\text{Cl}_3$). Lamy (*A. Ch.* [3] 67, 402) obtained a yellow, slightly hygroscopic, easily fusible solid, to which he assigned the composition TiCl_2 , by heating Ti and TiCl in a stream of Cl so that the product always remained liquid, and allowing to cool when saturated; the substance gave off Cl , and Ti_2Cl_3 remained.

THALLIUM SESQUICHLORIDE Ti_2Cl_3 ; or $\text{TiCl}_3.3\text{TiCl} = \text{Ti}_4\text{Cl}_{10}$ (Thallothallic chloride). Formed by heating dry TiCl_3 somewhat above 100° as long as Cl is given off; the brown liquid cools to a clear yellow, crystalline mass (Lamy, *l.c.*, p. 403). Also formed by the direct combination of Cl with molten Ti (*L.*, *l.c.*); also by ppg. a solution containing a thallic and a thallic salt by HClAq (Willm, *l.c.*). Also obtained by dissolving Ti or TiCl in *aqua regia*, evaporating, heating till Cl ceases to be given off, and crystallising from water slightly acidified with *aqua regia* (Lamy, *l.c.*; Crookes a. Church, *C. N.* 8, 1). According to Werther (*J. pr.* 91, 390) the product of this reaction, dried at 100° , is a mixture of compounds of TiCl and TiCl_3 , besides Ti_2Cl_3 . Ti_2Cl_3 crystallises in yellow, hexagonal leaflets; unchanged in air; melting between 400° and 500° to a dark-brown liquid that solidifies with much contraction, forming a yellowish mass with *S.G.* 5.9 (Lamy, *l.c.*). Very slightly soluble in water; *S.* 26 at 15° , 29 at 17° , 1.9 at 100° (Crookes; Hebberling, *A.* 134, 21). The solution is said to show the reactions both of thallic and thallic compounds. Heated above 500° Cl is given off; heating in H_2S produces Ti_2S , *S*, and HCl (Hebberling, *l.c.*). Heating in NH_3 produces TiCl , NH_4Cl , and *N* (Crookes a. Church, *C. N.* 8, 1). Ti_2Cl_3 reacts with KOH Aq to form TiO_2H_2 , TiCl , and KCl .

OTHER THALLO-THALLIC CHLORIDES. According to Werther (*J. pr.* 91, 390), two compounds

besides Tl_2Cl_4 are obtained by evaporating $TlCl$ in *aqua regia*, heating till Cl ceases to be given off, crystallising from water slightly acidified with *aqua regia*, and drying at 100° . To these compounds W. gives the formulæ $3TlCl \cdot 4TlCl_2$, $-Tl_2Cl_4$, and $TlCl \cdot 15TlCl_2 = Tl_2Cl_4$.

Thallium, cyanide of; v. vol. ii. p. 347.

Thallium, ferrocyanide of; v. vol. ii. p. 337.

Thallium, fluorides of. Only one fluoride of Tl has been isolated with certainty; there are indications of the existence of another.

THALLOUS FLUORIDE TlF . Formula probably molecular, from analogy of $TlCl$. Prepared by dissolving Tl_2CO_3 in $HFAq$, evaporating to dryness, heating gently to remove HF , and crystallising from water; forms white, lustrous, regular octahedra (Büchner, *J. pr.* 96, 404). TlF is also said to be formed as a white sublimate by heating Tl_2O in HF gas (Kuhlmann, *C. R.* 58, 1037). Sol. in water; $S. = 80$ at 15° , and increases with increase of temperature; solution in water has alkaline reaction; somewhat sol. in alcohol. A hydrate $TlF \cdot H_2O$ forms in monoclinic crystals by evaporating a solution of Tl_2O or Tl_2CO_3 in $HFAq$; it is deliquescent, and acts on glass (Kuhlmann, *l.c.*; Willm, *A. Ch.* [4] 5, 5). A compound with fluorhydric acid, $TlF \cdot HF = TlHF_2$, is obtained by evaporating a solution of TlF in $HFAq$ over H_2SO_4 . Decomposed above 100° to TlF and HF . V. sol. water; $S. = 100$ at ordinary temperature; the solution has an acid reaction (Büchner, *l.c.*).

THALLIC FLUORIDE. By digesting Tl_2O_3 with $HFAq$, and also by adding $HFAq$ to $Tl(NO_3)_3Aq$, Willm (*A. Ch.* [4] 5, 5) obtained a dark olive-green solid, becoming brown when heated, and melting to an orange-yellow liquid that became white on cooling, insoluble in water and in cold $HClAq$. This substance was probably thallic fluoride, or perhaps a thallothallic fluoride; no analyses are given.

Thallium, hydride of. Herapath (*Ph.* 4, 302) supposed that a compound of Tl and H existed; but Crookes (*C. J.* 17, 132) failed to obtain any compound either by the interaction of an acid with $Tl-Zn$ alloy, or by heating Tl in a stream of H ; the escaping H burnt with a green flame, but this was found to be due to particles of Tl carried by the stream of H .

Thallium, hydroxides of. Tl forms three compounds with O and H , namely, $TlOH$, Tl_2O_2H (or $Tl_2O \cdot OH$), and $Tl_2O_3H_2$.

THALLOUS HYDROXIDE $TlOH$. (Hydrated thalious oxide $Tl_2O \cdot H_2O$.) Mol. w. not known with certainty. Thomsen (*Th.* 3, 354) gives $H.F.$ $[Tl_2O, H] = 56,915$; $[Tl_2O, H \cdot O] = 45,470$; $[Tl_2O, H \cdot O] = 3,230$.

Formation.—1. By dissolving Tl in water containing air, and evaporating.—2. By decomposing Tl_2SO_4Aq by $BaOAq$, filtering, and evaporating.—3. By the interaction of $CaOAq$ and Tl_2O_3Aq .—4. By dissolving Tl_2O in water and evaporating.

Preparation.—1. Tl ppd. by zinc is allowed to oxidise in warm, moist air, and the oxide is dissolved in boiling water; these operations are repeated till a saturated hot solution is obtained, and this solution is evaporated a little, filtered from any Tl_2CO_3 that may have separated, and allowed to crystallise (Crookes, *C. J.* 17, 132).—2. Tl_2SO_4 is mixed with the proper quantity

of $BaOAq$, and the solution, filtered from $BaSO_4$, is crystallised *in vacuo*; this method is tedious, and there is much difficulty in getting rid of all BaO .—3. Thin plates of Tl are suspended over a shallow dish containing absolute alcohol, within a bell-jar from which air has been exhausted, and pure O is passed into the jar, the temperature being kept at 20° – 25° ; after several hours or days, C_2H_5TlO is formed as an oil in the dish; excess of alcohol is removed by heating to 100° ; a little water is added, whereby $TlOH$ is ppd.; the pp. is drained, and exposed to warm dry air till all water and alcohol are removed (Lamy, *A. Ch.* [3] 67, 385).

Properties and Reactions.—Pale-yellow, prismatic crystals. At 100° in air, or *in vacuo* over H_2SO_4 , at the ordinary temperature, the crystals become black from formation of Tl_2O , without altering their crystalline form. Easily soluble in water; Thomsen (*Th.* 3, 354) gives $[TlOH, Aq] = -3,155$. The solution in water resembles $KOHAq$ and $NaOHAq$ in its properties; it is strongly alkaline, absorbs CO_2 , ppts. heavy metals as hydroxides or oxides, feels soapy to the touch, stains the skin, neutralises acids, &c. The solution absorbs a little O on heating; when evaporated to dryness and the residue re-dissolved, a little Tl_2O_3 generally remains.

THALLIC HYDROXIDES. Two thallic hydroxides are known, $TlO \cdot OH$ and $Tl_2O_3H_2$.

I. Monohydrated thallic oxide, $TlO \cdot OH = Tl_2O_3H_2O$. Mol. w. not known with certainty.

Formation.—1. By ppg. $TlCl_3Aq$ by alkali and drying at 100° (Lamy, *A. Ch.* [3] 67, 385).—2. By passing ozonised air through $TlOHAq$ (Schönbein, *J. pr.* 93, 35).—3. By the action of H_2O_2Aq on Tl ; according to Weltzien (*A.* 138, 129) a mixture of $TlOH$ and $Tl_2O \cdot OH$ is thus obtained.—4. Various oxidisers—e.g. $KMnO_4Aq$, hypochlorite solutions, &c.—convert $TlOH$ into $Tl_2O \cdot OH$ (Schönbein, *l.c.*)—5. By electrolysis a neutral or ammoniacal solution of $Tl_2(SO_4)_3$ or $Tl(NO_3)_3$; the hydroxide separates on the positive (Pt) electrode (Flemming, *J. Z.* 1869, 292).

Preparation.— $TlCl_3Aq$ is ppd. by a slight excess of $KOHAq$ or NH_4Aq , the pp. is thoroughly washed, and dried at 100° (Lamy, *A. Ch.* [3] 67, 397; Crookes, *C. J.* 17, 132; Werther, *J. pr.* 91, 388). The air-dried pp. has the composition $Tl_2O \cdot OH$ (Carnelley a. Walker, *C. J.* 53, 88).

Properties and Reactions.—A brown powder; insoluble in water and dilute alkali solutions. Heated to $c. 60^\circ$ begins to lose water; completely dehydrated at 115° , according to Werther (*J. pr.* 91, 385), but the residue contains some Tl_2O , as well as Tl_2O_3 (cf. Birnbaum, *A.* 138, 133). According to Carnelley a. Walker (*C. J.* 53, 88), dehydration is complete at 230° , and the residue is Tl_2O_3 , which is stable to 360° . Dissolves in $HClAq$, forming $TlCl_3$; in conc. acid Cl is given off and some $TlCl$ is produced. Dissolves in dilute H_2SO_4Aq ; with conc. acid some O is given off. Dissolves in SO_4Aq , As_2O_3Aq , hot tartaric acid solution, and boiling oxalic acid solution, in each case forming a salt of Tl_2O . $Tl_2O \cdot OH$ dissolves in warm conc. NH_4ClAq , giving off NH_3 , and forming $TlCl_3 \cdot 3NH_3$; on adding water Tl_2O_3 is ppd. as a black powder (Willm, *A. Ch.* [4] 5, 5).

II. Trihydrated thallic oxide, $Tl_2O_3H_2 \cdot 3H_2O$. Formed, as light-brown, lustrous.

microscopic, hexagonal plates, by dissolving $\text{Tl}_2\text{O} \cdot \text{H}_2\text{O}$ in molten KOH , fusing for some time, cooling, washing with hot water, then with alcohol, and drying at 100° . Insoluble in water. Not decomposed at 340° ; soluble in dilute acids (Carnegie, *C. N.* 60, 113).

Thallium, iodides of. Tl combines directly with I . At least two compounds are known: TlI and TlI_2 ; TlI_2 , and probably one, or perhaps more than one, other compound of TlI and TlI_2 , seem also to exist.

Thallous iodide TlI . (*Thallium monoxide.*) Mol. w. not known with certainty, but formula TlI is probably molecular from analogy of TlCl .

Formation. — 1. By heating together Tl and I in the ratio TlI . — 2. By adding KIAq to solution of a thallous salt.

Preparation. — KIAq is added to a dilute solution of a thallous salt, and the yellow pp. is thoroughly washed with water and dried at 100° (Lamy, *A. Ch.* [3] 67, 405; Crookes, *C. J.* 17, 137).

Properties and Reactions. — A citron-yellow powder; melts at 439° (Carnelley, *C. J.* 33, 278), and boils at 800° – 806° (C. a. Williams, *C. J.* 33, 284). S.G. 7.072 at 15.5° , after fusion 7.0975 at 14.7° (Twitchell, *Clarke's Table of Spec. Grav.* [2nd edit.] 35). Very slightly soluble in water. Determinations of solubility vary considerably; Werther (*J. pr.* 92, 130) says that 1 pt. requires 20,000 pts. water to dissolve it at 15° , and Crookes (*l.c.*) gives solubility as 1 in 4450 of water at 15° (v. also Heberling, *A.* 134, 16). Crookes says TlI is somewhat more soluble, Heberling says it is decidedly less soluble, in KIAq than in water.

When heated to $c. 190^\circ$ TlI becomes red, and when it melts a red liquid is formed which solidifies to a red crystalline mass having the composition TlI (Heberling, *l.c.*, p. 18); the red variety is also obtained by crystallising from hot KOHAc (Willm, *A. Ch.* [4] 5, 28); also by crystallising from hot $\text{K}_2\text{C}_2\text{O}_4\text{Ac}$ (Werther, *l.c.*). The red form of TlI is produced by adding KIAq to a warm conc. solution of a thallous salt (Heberling, *l.c.*, p. 16). Red TlI crystallises in octahedral forms (W., *l.c.*). The red variety slowly changes on keeping to the yellow form.

When freshly ppd. yellow TlI is exposed to the sun's rays it becomes green and crystalline without any change in composition. The green variety of TlI is somewhat more soluble in hot water than the yellow form; it crystallises from hot water in green microscopic crystals that are very refractive. The green variety changes slowly to the yellow on keeping; the change is hastened by heating in water containing I or KI , but not by heating with pure water. When strongly heated, green TlI becomes red (v. Knösel, *B.* 7, 576, 593).

TlI is decomposed by warm HNO_3Ac , with separation of I . It is dissolved, without I being separated, by ClAc or *aqua regia*; Willm (*l.c.*) supposes that an iodochloride is formed. Fusion with KCN produces Ti (Werther, *l.c.*).

Thallic iodide TlI_2 . This compound has not been isolated with certainty. By treating Ti with an ethereal solution of I , Nicklès (*C. R.* 53, 537) obtained a brown liquid from which brown needles gradually separated. These crys-

tals may have been TlI_2 ; no analyses are given.

Double salts of TlI_2 with alkali iodides have been prepared by digesting TlI with solutions of I and alkali iodides in ether; these salts have the composition $\text{TlI}_2 \cdot \text{MI} \cdot x\text{H}_2\text{O}$, where $\text{M} = \text{NH}_4$ and K (v. Nicklès, *J. Ph.* [4] 1, 25; Willm, *A. Ch.* [4] 5, 5; Rammelsberg, *P.* 146, 597). A compound $\text{TlI}_2 \cdot \text{CuI}_2 \cdot 8\text{NH}_3$ is described by Jörgensen (*J. pr.* [2] 6, 82).

Thallium sesqui-iodide Tl_2I_3 or $\text{TlI}_2 \cdot 3\text{TlI}$ — Tl_2I_4 . (*Thallothallic iodide.*) Black, lustrous needles; insoluble in water, slightly soluble cold alcohol, decomposed by boiling alcohol; decomposed slowly at ordinary temperature, quickly on heating; obtained by long-continued heating yellow TlI with excess of IAq (Knösel, *B.* 7, 576, 593).

OTHER THALLO-THALLIC IODIDES. By evaporating a solution of TlI in HIAq , in presence of I , at 70° , small, brown, rhombic, crystals were obtained by Jörgensen (*l.c.*). The composition of the crystals is represented by J. as $6\text{TlI} \cdot \text{TlI}_2$, or perhaps $5\text{TlI} \cdot \text{TlI}_2$. The same compound is said to be obtained by digesting TlI with an ethereal solution of I . Heating to $c. 100^\circ$ drives off I , and leaves yellow TlI ; boiling alcohol, and also KIAq , withdraws I , forming TlI .

Thallium, oxides of. Two oxides have been isolated, Tl_2O and Tl_2O_3 ; there is evidence in favour of the existence of a third oxide, probably TlO_2 .

Thallous oxide Tl_2O . (*Thallium monoxide.*) Mol. w. not known with certainty. [Ti_2O] = 42,240 (*Th.* 3, 354). Prepared by heating Ti in air to not above 100° (to prevent formation of Tl_2O_3); also by heating TlOH to 100° out of contact with air; also by heating Tl_2O_3 to full redness. A black powder; melting at $c. 300^\circ$ to a dark-yellow liquid, which acts on glass, forming a silicate of Ti . Tl_2O absorbs moisture from the air, forming TlOH ; it dissolves easily in water, forming a strongly alkaline solution of TlOH (v. Thallous hydroxide, p. 678). Soluble in absolute alcohol, forming $\text{C}_2\text{H}_5\text{OTl}$, a colourless, heavy oil (S.G. 3.55); this oil is decomposed by a little water with separation of TlOH (v. Thallous hydroxide, Preparation, No. 3, p. 678). (Crookes, *C. J.* 17, 128; Lamy, *A. Ch.* [3] 67, 385). Tl_2O is reduced to Ti by heating to redness in H_2 or in CO , or with Mg (Winkler, *B.* 23, 788).

Thallic oxide Tl_2O_3 . Mol. w. not known with certainty. Prepared by ppg. a thallic salt with KOHAc or NH_4Ac , washing the pp. thoroughly, drying, and heating it to $c. 260^\circ$ (Crookes, *l.c.*, p. 132). Also formed by burning Ti in air to a little below redness; at a lower temperature the product is chiefly Tl_2O , and at a full red heat Tl_2O_3 is decomposed to Tl_2O and O (Lamy, *l.c.*). Tl_2O_3 is also formed by passing an electric current (from a couple of Grove cells) through neutral $\text{Ti}_2\text{SO}_4\text{Ac}$, using Pt electrodes; Ti deposits on the negative electrode, and Tl_2O_3 forms, as a brown cake, on the positive electrode; the $\text{H}_2\text{SO}_4\text{Ac}$ formed should be neutralised from time to time by NH_4Ac (Crookes, *l.c.*). For other methods of formation v. Wöhler (*A.* 146, 263, 375), and Willm (*A. Ch.* [4] 5, 19). Tl_2O_3 is a brownish-black solid; insoluble in water. Melts at $c. 760^\circ$ (?) (Carnelley a. O'Shea, *C. J.*

45, 409). Gives off O at a full red heat, forming TiO_2 . Dissolves in hot $\text{H}_2\text{SO}_4\text{Aq}$, forming $\text{Ti}_2\text{SO}_4\text{Aq}$ and giving off O. Soluble cold HClAq , forming TiCl_3Aq , and some TiCl with evolution of Cl. Takes fire in dry H_2S , forming Ti_2S_3 (Carstanjen, *J. pr.* 102, 65). A mixture of TiO_2 and S takes fire when struck (Böttger, *J. pr.* 90, 27). Reduced by heating in H or CO to Ti_2O_3 , and then to Ti . Ti_2O_3 absorbs NH_3 when heated in that gas; no definite compound has been isolated. For compounds with H_2O v. THALLIUM HYDROXIDES, p. 678).

THALLIUM DIOXIDE ($?\text{TiO}_2$). When a rapid stream of Cl is passed into conc. KOHAg , holding freshly ppd. TiO.OH in suspension, a violet-coloured solution is obtained; mineral acids added to this solution form thallous salts, and give off O, or Cl with HClAq . Carstanjen (*J. pr.* 101, 55) supposed the violet solution to contain a thallate of potassium. Piccini (*G.* 17, 450) obtained a violet pp. by adding $\text{Ba(NO}_3)_2\text{Aq}$ to the violet solution; analyses of this pp. were not satisfactory, but the results indicated that an oxide of Tl of the composition TiO_2 is formed by the method described. Piccini says that the same violet solution is obtained by electrolysis 30 p.c. KOHAg , using a plate of Tl as anode; also by digesting 1 pt. KOH with 4 pts. KClO_4 in water, and adding Ti_2SO_4 .

Thallium, phosphide of. No compound of Tl and P has been isolated with certainty. According to Crookes (*C. J.* 17, 185), the black substance formed by passing P hydride into ammoniacal $\text{Ti}_2\text{SO}_4\text{Aq}$ is a phosphide of Tl. Carstanjen (*J. pr.* 102, 80) failed to obtain a phosphide by reducing Ti_2PO_4 by C or H, or by heating the elements together. Flemming (*Bl.* [2] 10, 35) noticed that a thin, black coating formed on molten Tl when pieces of P were thrown on to it; by heating solution of a thallous salt with P in a sealed tube, he obtained a black solid, perhaps a phosphide, and also a phosphite and hydride of P (*cf.* Willm, *A. Ch.* [4] 5, 5).

Thallium, platino-cyanide of; v. vol. ii. p. 345.

Thallium, salts of. Two series of salts are formed by replacing the H of acids by Tl; thallous salts, Ti_2X , and thallic salts, TiX_3 , where $\text{X} = \text{SO}_3, \text{CO}_3, 2\text{NO}_3, 2\text{IO}_3, \frac{2}{3}\text{PO}_4, \&c.$ The chief thallous salts of oxyacids are *arsenates, carbonates, chlorate and perchlorate, chromate, dichromate and trichromate, dithionate and trithionate, hypophosphite, iodate and periodate, molybdates, nitrate, phosphates, selenite and selenates, silicates, sulphates and sulphite, tellurate, thiosulphate*. The principal thallic salts are *arsenate, iodate and periodate, nitrate, phosphates, sulphates* (v. CARBONATES, NITRATES, SULPHATES, &c.). Several double salts of both series are also known.

Thallium, salts of oxyacids of. No compounds of this kind have been isolated with certainty, but there is evidence in favour of the existence of salts of the hypothetical thallic acid, probably analogous to plumbates (v. THALLIUM DIOXIDE, *supra*).

Thallium, selenides of. Ti_2Se has been isolated; another selenide, perhaps Ti_2Se_3 , probably exists.

THALLOUS SELENIDE Ti_2Se . Mol. w. not known. Obtained by fusing the elements toge-

ther in the ratio 2Tl:Se (Willm, *A. Ch.* [4] 5, 5; Carstanjen, *J. pr.* 102, 79); also by ppng. $\text{Ti}_2\text{CO}_3\text{Aq}$ by H_2Se (Kuhlmann, *Bl.* [2] 1, 380). A grey, lustrous, crystalline solid; melting at c. 840° (Kuhlmann, *l.c.*). Dissolves in $\text{H}_2\text{SO}_4\text{Aq}$ and HClAq , giving off H_2Se .

THALLIC SELENIDE ($?\text{Ti}_2\text{Se}_3$). By fusing the elements together in the ratio 2Tl:3Se, Carstanjen (*l.c.*) obtained greyish-black prismatic crystals, resembling Sb; not acted on by dilute $\text{H}_2\text{SO}_4\text{Aq}$; decomposed by hot conc. H_2SO_4 , with separation of Se and evolution of SO_2 . The composition of this substance has not been determined.

Thallium, silicofluoride of, Ti_2SiF_6 . Obtained by dissolving Ti_2CO_3 in $\text{H}_2\text{SiF}_6\text{Aq}$, and evaporating. Colourless, regular, octahedra (Werther, *J. pr.* 91, 385). According to Kuhlmann (*Bl.* [2] 1, 380), the crystals are $\text{Ti}_2\text{SiF}_6 \cdot \text{H}_2\text{O}$. Easily soluble in water. Volatile without decomposition, according to Kuhlmann (*l.c.*).

Thallium, sulphides of. Ti_2S and Ti_2S_3 have been isolated, and also probably more than one compound of these two sulphides.

THALLOUS SULPHIDE Ti_2S . Mol. w. not known.

Formation.—1. By fusing the elements together in the ratio 2Tl:S (Carstanjen, *J. pr.* 102, 76).—2. By ppng. an alkaline solution of a thallous salt by H_2S .—3. By ppng. slightly acidified $\text{Ti}_2\text{SO}_4\text{Aq}$ by H_2S (Hebberling, *A.* 134, 11).—4. By heating an alkaline solution of a thallous salt with $\text{Na}_2\text{S}_2\text{O}_3$ (C, *l.c.*).

Preparation.—A cold, fairly conc., aqueous solution of Ti_2SO_4 is acidulated with a trace of $\text{H}_2\text{SO}_4\text{Aq}$, and saturated with H_2S , and the bluish-black pp., consisting of microscopic crystals, is washed with H_2SAq and dried over H_2SO_4 (Hebberling, *l.c.*).

Properties and Reactions.—Prepared by ppn. from slightly acidulated $\text{Ti}_2\text{SO}_4\text{Aq}$, Ti_2S forms very minute, blue-black, lustrous tetrahedra; prepared by heating together Tl and S it is a black, crystalline, brittle solid; prepared by ppn. from alkaline solutions it is a black amorphous solid. When the amorphous solid is dried, and strongly heated, it melts, and solidifies on cooling to a black crystalline mass. After melting, S.G. is 8.0 (Lamy, *J.* 15, 185). H.F. [Ti_2S] = 21,660 (*Th.* 3, 354). Moist ppd. Ti_2S oxidises in air to Ti_2SO_4 . On long continued heating Ti_2S is completely decomposed (Lamy, *l.c.*). Ti_2S is insoluble in solutions of alkalis, alkali sulphides, carbonates, and cyanides; it dissolves readily in $\text{H}_2\text{SO}_4\text{Aq}$ and HNO_3Aq , and less readily in HClAq . By ppng. from a very dilute solution of a thallous salt, and dialysing, Winssinger (*Bl.* [2] 49, 452) obtained a reddish-brown aqueous solution of colloidal Ti_2S .

Combination.—By passing H_2S into $\text{Ti}_2\text{SO}_4\text{Aq}$ containing $\text{As}_2\text{O}_3\text{Aq}$, and acidulated with dilute $\text{H}_2\text{SO}_4\text{Aq}$, Gunning (*Ar. N.* 3, 86) obtained a red pp. of $\text{Ti}_2\text{S} \cdot \text{As}_2\text{S}_3$; the same compound was obtained by mixing a solution of As_2S_3 in NH_4Aq with an ammoniacal solution of a thallous salt. Heat decomposes the compound into its constituent sulphides; alkali solutions dissolve out As_2S_3 , leaving Ti_2S .

THALLIC SULPHIDE Ti_2S_3 . Obtained as a black, amorphous, easily fusible, solid, by melting Tl with excess of S, and removing uncon-

bined S by heating out of contact with air (Carstanjen, *J. pr.* 102, 65). Below 12° Ti_2S_3 is hard and brittle; above 12° it is so soft that it may be drawn out like pitch. It dissolves in warm dilute H_2SO_4 without separation of S. Strecker (*J. pr.* [2] 2, 162) obtained a lustrous, brown-black pp. by passing H_2S into a solution of a thallic salt mixed with sodium tartrate and excess of NH_4Aq , followed by boiling; this pp. was Ti_2S_3 according to Strecker. When H_2S is passed into an aqueous solution of a thallic salt, the pp. is a mixture of Ti_2S_3 and S. Ti_2S_3 combines with potassium and sodium sulphides, forming $\text{Ti}_2\text{S}_3 \cdot \text{K}_2\text{S}$ and $\text{Ti}_2\text{S}_3 \cdot \text{Na}_2\text{S}$. These compounds are obtained by fusing together 1 pt. Ti_2SO_4 , 6 pts. S, and 9 pts. K_2CO_3 or Na_2CO_3 , and washing the fused mass with water. The K compound is more stable than the compound of Na; when heated it melts, and then gives off S, leaving K₂S and Ti_2S_3 ; it is not changed by water or alkali solutions, but is decomposed by mineral acids (v. Schneider, *A.* 135, 215; cf. Krüss, *B.* 19, 2738). These compounds may be regarded as KTiS_3 and NaTiS_3 , that is, as salts of a hypothetical thio-thallic acid.

THALLO-THALIC SULPHIDES. By adding $(\text{NH}_4)_2\text{SAq}$ to a solution of TiCl_3 , a black pp. is obtained which is more fusible than Ti_2S_3 , and after melting solidifies to large greyish-black prisms. This pp. contains Ti and S. Similar substances are formed by heating together Ti_2S_3 and Ti_2S_3 , and by melting Ti with more S than $2\text{Ti}:\text{S}$, and less than $2\text{Ti}:\text{S}:\text{S}$; Carstanjen (*J. pr.* 102, 65) gave the formulæ $5\text{Ti}_2\text{S}_3 \cdot 3\text{Ti}_2\text{S}_3 = \text{Ti}_{16}\text{S}_{14}$, and $\text{Ti}_2\text{S}_3 \cdot \text{Ti}_2\text{S}_3 = \text{TiS}$ to compounds obtained in this way. By heating $\text{Ti}_2\text{S}_3 \cdot \text{Na}_2\text{S}$ (v. *supra*) with water, Schneider (*A.* 135, 215) obtained a compound to which he gave the formula $\text{Ti}_2\text{S}_3 \cdot 2\text{Ti}_2\text{S}_3 = \text{Ti}_6\text{S}_6$.

Thallium, sulphocyanide of; v. vol. ii. p. 352.

Thallium, thioisals of. The compounds of Ti_2S_3 with K_2S and Na_2S may be regarded as K and Na thiothallates (v. **THALIC SULPHIDE**, *supra*).

M. M. P. M.

THALLIUM ETHIDE TiEt . Has not been obtained in the free state.

Ethylchloride TiEt_2Cl . S. 2.76 in the cold; 3.87 at 92° . S. (alcohol) $.33$ at 78° . Formed from TiCl_3 and ZnEt_2 in ether (Hartwig, *A.* 176, 257). Scales (from water), explodes feebly at 190° , yielding TiCl . Reacts with silver salts forming: TiEt_2NO_3 , S. 5.67 at 70° , exploding at 236° .— $(\text{TiEt}_2)_2\text{SO}_4$, S. 65.4 in the cold; 87.3 at 90° ; exploding at 205° and converted by BaI_2 into TiEt_2I , S. $.1$, exploding at 195° .— $(\text{TiEt}_2)_2\text{PO}_4$, S. 23.7 in the cold; 20.7 at 75° , exploding at 189° .— TiEt_2OAc crystallising in needles [212° (245°)], exploding if rapidly heated.

Ethylhydroxide TiEt_2OH . S. 15.1 in the cold; 8 at 88° . Formed from $(\text{TiEt}_2)_2\text{SO}_4$ and baryta. Silky needles (from water). More sol. cold than hot water, forming an alkaline solution. Does not unite with CO_2 , but forms the above salts with other acids.

THAPSIC ACID $\text{C}_{17}\text{H}_{25}\text{O}_7$. [124°]. Obtained from the root-bark of *Thapsia garganica*. The bark is extracted with ether, which leaves on evaporation an amber-coloured resin. The resin dissolves in potash with evolution of heat, and the solution, on acidification, yields a neutral resin, *n*-octoic acid and thapsic acid. The

alkaline solution on standing deposits potassium thapsate (Canzoneri, *G.* 13, 514). White scales (from alcohol), nearly insol. water and benzene, sol. alcohol and ether.

Salts.— $\text{KA}''\text{z}$ aq. Prisms.— BaA'' (dried at 120°). Crystalline pp.— AgA'' : amorphous.

Anhydride $\text{C}_{17}\text{H}_{25}\text{O}_7$. [71°]. Crystalline powder (from benzene).

Anilide $\text{C}_{17}\text{H}_{25}\text{O}_7(\text{NHPh})$. [163°].

THEBAÏNE $\text{C}_{17}\text{H}_{21}\text{NO}_3$. [198°]. S.G. 1.3. $[\alpha]_D = -219^{\circ}$ in 97 p.c. alcohol at 15° ; $= -230^{\circ}$ in CHCl_3 ; S. (ether) $.7$ at 10° ; S. (isoamyl alcohol) 1.67 in the cold; S. (benzene) 5.27 in the cold (Kubly, *J.* 1866, 823). Occurs in opium to the extent of about .6 p.c. (Pelletier, *J. Ph.* 21, 569; Courbe, *A. Ch.* [2] 59, 155; Kane, *A.* 19, 9; Anderson, *A.* 86, 179; Hesse, *B.* 3, 367; *A.* 153, 47; 176, 196). Prepared by treating the aqueous extract of opium with Na_2CO_3 or lime, exhausting the filtrate with ether, agitating the ether with dilute acetic acid, and pouring the acid liquid into dilute KOH aq. The pp. is collected after 24 hours, warmed with dilute alcohol and dilute HOAc is added till just acid. The alcohol is evaporated off at 50° , papaverine and narcotine removed by filtration, and thebaïne acid tartrate ppd. by adding powdered tartaric acid to the filtrate. The tartrate is re-crystallised from water (Hesse, *A. Suppl.* 8, 262). Thebaïne may also be obtained by adding NaOAc to a solution of the hydrochlorides of the opium alkaloids, allowing to stand, filtering, evaporating, again filtering, and adding sodium salicylate. After 24 hours thebaïne salicylate crystallises (Plugge, *Ar. Ph.* [3] 24, 993; 25, 343).

Properties.—Colourless leaflets (from dilute alcohol) or prisms (from conc. alcohol). Tasteless. Alkaline in reaction. Very poisonous. Begins to sublime at 135° ; at 160° the sublimate contains needles, cubes, and prisms (Blyth). V. sol. alcohol and chloroform. Ppd. by alkalis and alkaline carbonates, the pp. being slightly soluble in NH_4Aq and lime-water. Conc. H_2SO_4 gives a deep-red solution. Boiling dilute H_2SO_4 converts it into thebenine and thebaïne. Hot conc. HClAq at 90° yields MeCl and morphothebaïne (Howard, *B.* 17, 527). HI aq gives MeI (2 mols.) (Howard & Roser, *B.* 19, 1597). Bromine-water forms $\text{C}_{17}\text{H}_{21}\text{BrNO}_3$, a flocculent pp. converted by excess of Br into $\text{C}_{17}\text{H}_{21}\text{Br}_2\text{NO}_3$, a yellow pp. Solutions of its salts give a pp. of the dichromate on adding $\text{K}_2\text{Cr}_2\text{O}_7$.

Salts.— B^+HCl aq. Large trimetric prisms. S. $.63$ at 10° . $[\alpha]_D = -168.32 + 2.33p$.— $\text{B}^+\text{H}_2\text{PtCl}_2\text{z}$ aq. Amorphous pp., quickly changing to orange prisms. Decomposed by boiling water (O. De Coninck, *Bl.* [2] 45, 131).— $\text{B}^+\text{H}_2\text{C}_2\text{O}_4$ 6aq. S. 1.03 at 10° .— $\text{B}^+\text{H}_2\text{C}_2\text{O}_4$ aq. S. 2.3 at 20° .— $\text{B}^+\text{C}_2\text{H}_3\text{O}_4$ aq. Prisms, very soluble in hot alcohol. S. $.77$ at 20° .—Meconate $\text{B}^+\text{C}_2\text{H}_3\text{O}_4$ 6aq. White prisms (from alcohol).— $\text{B}^+\text{H}_2\text{FeCy}_2$ (Plugge, *Ar. Ph.* [3] 25, 793).

Methyl-iodide B^+MeI . Crystallises from alcohol in prisms (containing EtOH), m. sol. water.

Ethylchloride B^+EtCl . Needles.

Ethyl-iodide B^+EtI . Needles (from alcohol) (Howard, *B.* 17, 527).

Benzylchloride $\text{B}^+\text{C}_6\text{H}_5\text{Cl}$. Crystals.

Morpho-thebaïne $\text{C}_{17}\text{H}_{21}\text{O}_3\text{N}$ [191°]. Obtained by heating thebaïne with strong aqueous HCl or

HBr, MeCl (or EtCl) being split off; the yield being 50 p.c. of the thebaine. Yellowish crystals. Soluble in alcohol, ether, and benzene, sparingly in water. It dissolves in H_2SO_4 to a colourless solution.

Salts.—B'HCl. Small glistening crystals, sol. water, insol. alcohol.—B'HBr: fine silky needles.—B'HNO₃ 2aq: small white crystals, v. sol. water and alcohol.—B'₂H₂SO₄ 7aq: small crystals, v. sol. water, insol. alcohol. The oxalate is a sparingly soluble amorphous pp. The picrate is a yellow pp. which melts under water. Insoluble pps. are produced with potassium ferrocyanide, ammonium molybdate, $\text{HgCl}_2\cdot\text{K}_2\text{I}_2$, $\text{K}_2\text{Cr}_2\text{O}_7$, and bismuth-potassium iodide.

Acetyl derivative $\text{C}_{17}\text{H}_{19}\text{AcO}_2\text{N}$. [183°]: glistening plates (Howard, B. 17, 529).

Ethyl-iodide *B'EtI. Crystallises from acetic acid.

Methylo-iodide B'MeI. Dimetric tables, insol. alcohol, sol. HOAc.

Benzyl-chloride *B'C₆H₅Cl. Needles, m. sol. water, sl. sol. alcohol (Howard a. Roser, B. 19, 1596).

Thebenine $\text{C}_{19}\text{H}_{21}\text{NO}_3$. Formed by boiling thebaine with HClAq (S.G. 1.04) (Hesse, A. 153, 69). Amorphous. Insol. benzene and ether, sl. sol. boiling alcohol. Conc. H_2SO_4 forms a blue solution. V. sol. KOHAq.—B'HCl 3aq. S. 1. Plates.—B'₂H₂HgCl₂ 2aq. Very long efflorescent prisms.—B'₂H₂SO₄ 2aq. Plates, insol. cold water.—B'₂H₂C₂O₄ aq. Prisms, sl. sol. hot water.

Thebaïcine. Formed by boiling thebaine or thebenine with conc. HClAq (Hesse). Yellow amorphous pp., insol. ether, benzene, and water, sl. sol. hot alcohol, v. sol. KOHAq. Conc. H_2SO_4 forms a dark-blue solution. The salts are resins.

Theïne v. Caffeïne.

THEOBROMINE $\text{C}_7\text{H}_7\text{N}_2\text{O}_2$ i.e.

$\text{CO} \begin{smallmatrix} \text{NMe} \cdot \text{C} \cdot \text{CH} \cdot \text{NMe} \\ \text{N} = \text{C} \cdot \text{NH} \cdot \text{CO} \end{smallmatrix}$. Mol. w. 180. Di-

methyl-xanthine. S. 0.62 at 17°; .7 at 100°. S. (alcohol) .02 at 17°; .2 at 78°. S. (ether) .006 in the cold; .17 at 35°. S. (boiling CHCl_3) 1. Occurs in the seeds of *Theobroma cacao* to the extent of 1.3 to 4.6 p.c. (Woskresensky, A. 41, 125; Glasson, A. 61, 335; Keller, A. 92, 71; Roehleder, A. 71, 9; 79, 124; Strecker, A. 118, 151). Formed by heating the lead salt of xanthine $\text{C}_7\text{H}_7\text{PbN}_2\text{O}_2$ (4 pts.) with MeI (5 pts.) for twelve hours at 130° (Fischer, B. 15, 454; A. 215, 311). Prepared by ppg. the aqueous extract of the seeds with lead acetate, filtering, removing excess of lead by H_2SO_4 , adding MgCO_3 , evaporating to dryness, and extracting with alcohol (Dragendorff, Ar. Ph. [3] 13, 1). Got also by freeing cacao from oil by pressure, adding slaked lime, and extracting with 80 p.c. alcohol (Schmidt a. Pressler, A. 217, 287).

Properties.—Minute trimetric crystals, sl. sol. hot water, alcohol, and ether. Tastes bitter. At 134° it begins to sublime; at 170° (Blyth) or 290° (S. a. P.) it yields a crystalline sublimate. Very slowly attacked by pure HNO_3 (Franchimont, R. T. C. 6, 223). Not attacked by boiling KOHAq. Its salts are more or less easily decomposed by water. Ammoniacal AgNO_3 gives a gelatinous pp. which dissolves on warming, and deposits, on boiling, crystalline $\text{C}_7\text{H}_7\text{AgN}_2\text{O}_2$

(Strecker). Theobromine is ppd. by sodium phosphotungstate (Wolfram, C. J. 36, 406; Fr. 18, 346).

Reactions.—1. Yields methyl-parabanic acid on oxidation by CrO_3 .—2. KClO_3 and HClAq at 50° yield methyl-alloxan and methyl-urea (Fischer, A. 215, 304). Chlorine-water yields amalic acid.—3. Will not combine with MeI to form a methyl-iodide. But in presence of dilute alcoholic KOH it reacts with MeI, forming caffeine, even in the cold; better at 100°. But the reaction is never complete, some theobromine being decomposed.—4. Conc. HCl has no action below 200°. At 250° it decomposes it, producing formic acid, carbonic acid, ammonia, methylamine and sarcosine, $\text{C}_7\text{H}_7\text{N}_2\text{O}_2 + 6\text{H}_2\text{O} = 2\text{CO}_2 + \text{NMeH}_2 + 2\text{NH}_3 + \text{C}_4\text{H}_7\text{NO}_2 + \text{CH}_3\text{O}_2$; the NH_3 and NMeH_2 occur in the proportion indicated by the formula (Schmidt, A. 217, 298). Boiling aqueous Ba(OH)₂ effects in 40 hours the same decomposition.—5. HNO_3 forms CO_2 , methyl-parabanic acid and methylamine, but no ammonia.

Salts.—B'HCl aq. Rosettes of needles.—B'HBr aq. Tables.—B'₂H₂PtCl₄ 4aq.—B'₂H₂PtCl₅ 5aq.—B'HAuCl₄.—B'₂H₂NO₃.—B'HOAc.—B'₂H₂I₂. Nearly black prisms, decomposed by alcohol (Jörgenssen, Z. [2] 5, 675).—B'HAq(NO₃)₂. Silvery needles, v. sl. sol. water.— $\text{C}_7\text{H}_7\text{AgN}_2\text{O}_2\cdot\frac{1}{2}\text{aq}$.—Ba($\text{C}_7\text{H}_7\text{N}_2\text{O}_2$)₂ (dried at 105°). Got by adding theobromine to baryta-water (Maly a. Andreasch, M. 4, 379). Needles (from hot water).

Bromo-theobromine $\text{C}_7\text{H}_7\text{N}_2\text{O}_2\text{Br}$. From theobromine and bromine (Fischer, A. 215, 305). Crystalline powder. Sl. sol. hot water. Sol. HCl, but reppd. by water. Sol. aqueous NaOH, not in NH_3 . Does not give an ethoxy-derivative with alcoholic KOH (unlike bromo-caffeine). After warming with ammonia it gives with ammoniacal AgNO_3 a silver salt that can be converted by EtI into bromo-ethyl-theobromine $\text{C}_7\text{H}_7\text{EtN}_2\text{O}_2\text{Br}$, whence alcoholic KOH forms ethoxy-ethyl-theobromine $\text{C}_7\text{H}_7\text{EtN}_2\text{O}_2(\text{OEt})$ [153°] as needles. Boiling HCl converts this into EtCl and oxy-ethyl-theobromine $\text{C}_7\text{H}_7\text{EtN}_2\text{O}_2(\text{OH})$, whence bromine and alcohol form the di-ethyl derivative of tri-oxy-di-hydro-ethyl-theobromine $\text{C}_7\text{H}_7\text{EtN}_2\text{O}_2(\text{OH})(\text{OEt})_2$ [152°]. This body on treatment with hot dilute HCl gives methylamine and apo-ethyl-theobromine (?); and with chlorine at -10° forms hypo-ethyl-theobromine $\text{C}_7\text{H}_7\text{N}_2\text{O}_2$ [142°].

Methyl-theobromine is Caffeïne.

Ethyl-theobromine $\text{C}_7\text{H}_7\text{EtN}_2\text{O}_2$ [above 270°]. Formed from $\text{C}_7\text{H}_7\text{AgN}_2\text{O}_2$ and EtI (Philips, B. 9, 1308). Small crystals, m. sol. hot water. Weak base.

THEOPHYLLIN $\text{C}_7\text{H}_7\text{N}_2\text{O}_2$ i.e.

$\text{CO} \begin{smallmatrix} \text{NH} \cdot \text{C} \cdot \text{CH} \cdot \text{NMe} \\ \text{N} = \text{C} \cdot \text{NMe} \cdot \text{CO} \end{smallmatrix}$. [264°]. Occurs in alco-

holic extract of tea, from which it may be separated by means of its Ag salt (Kossel, B. 21, 2164). Monoclinic tables (containing aq. v. e. sol. warm water and very dilute ammonia. May be sublimed. When evaporated with chlorine-water it yields a scarlet residue, which is coloured violet by NH_4Aq . MeI converts its Ag salt into caffeine. KClO_3 and HClAq yield dimethyl-alloxan.

Salt.— $\text{AgC}_6\text{H}_4\text{N}_2\text{O}_2$ aq. Amorphous pp., which may be crystallised from NH_3 aq.

THETINES. A name given by Crum-Brown and Letts to compounds of the form $\text{CO}_2\text{H}.\text{CH}_2.\text{SR}_2.\text{OH}$ or their anhydrides $\text{CH}_2.\text{SR}_2$ where R is a hydrocarbon radicle; v. CO-O

DI-ETHYL-THETINE and DI-METHYL-THETINE.

THEVETIN $\text{C}_{14}\text{H}_{18}\text{O}_2$ aq. [170°]. S. 8 at 14°. $\alpha = -85.5^\circ$. A poisonous glucoside occurring in the kernels of *Thevetia nereifolia* (Blas, J. 1868, 768; De Vrij, R. T. C. 3, 167; Warden, Ph. [3] 12, 417). Crystalline powder, v. sol. hot water and alcohol, insol. ether. Sol. acids and alkalis. Lævorotatory. Conc. H_2SO_4 gives a dirty-brown colour. Decomposed by boiling dilute HCl aq into glucose and theveresin $\text{C}_{16}\text{H}_{20}\text{O}_2$, 2aq, a white powder [140°], v. sl. sol. cold water, sol. alkalis.

THIACETIC ACID v. THIO-ACETIC ACID.

THIALDINE $\text{C}_6\text{H}_{13}\text{NS}_2$ i.e.

$\text{NH} \begin{smallmatrix} \text{CHMe.S} \\ \text{CHMe.S} \end{smallmatrix} \text{CHMe.}$ Mol. w. 163. [43°].

Formed by passing H_2S for four hours into a solution of aldehyde-ammonia (1 pt.) in water (15 pts.), and a little NH_3 aq (Wöhler a. Liebig, A. 61, 2; Hofman, A. 103, 93; Brusewitz a. Cathander, J. pr. 98, 315). Monoclinic crystals (from ether-alcohol). May be distilled with steam. V. sl. sol. water, v. sol. alcohol, v. e. sol. ether. Boiling dilute H_2SO_4 forms thio-acetic aldehyde. KMnO_4 forms $\text{CH}_3.\text{CH}(\text{SO}_3\text{K})_2$ (Guareschi, B. 11, 1384, 1692). Boiling AgNO_3 aq forms aldehyde. MeI in ether forms crystalline $\text{C}_6\text{H}_{13}\text{MeNS}_2\text{I}$ (Hofmann, A. 103, 93). I in KI forms amorphous $(\text{CHMe})_2\text{S}_2$ (Fassbender, B. 20, 460).

Salts.— B'HCl . Prisms, v. sol. water.— B'HB'r — B'HI — B'HNO_3 — $\text{B'H}_2\text{SO}_4$. Prisms.— $\text{B'H}_2\text{PO}_4$ aq. Needles, v. sol. water.

THIAZOLE $\text{N} \begin{smallmatrix} \text{CH.S} \\ \text{CH.CH} \end{smallmatrix}$ (116.8° cor.). S.G.

$\frac{1}{2}$ 1-1799; $\frac{1}{2}$ 1-1998. Formed by the action of boiling alcohol on the diazo-compound of amido-thiazole, obtained from di-chloro-di-ethyl oxide and thio-urea (Hantzsch a. Popp, B. 21, 2582; A. 250, 274). Formed also from $\text{N} \begin{smallmatrix} \text{CCL.S} \\ \text{CH.CH} \end{smallmatrix}$

and the corresponding μ -bromo-thiazole by reduction with zinc-dust and HOAc (Schatzmann, A. 261, 12). Mobile liquid, very volatile, hygroscopic, and highly refractive. Miscible with water, alcohol, and ether. Insol. KOH aq. Smells like pyridine. Neutral in reaction.—**Salts.**— $\text{B'H}_2\text{PtCl}_4$ 2aq.— B'HAuCl_4 . [250°].— $\text{B'C}_6\text{H}_5\text{N}_3\text{O}_7$. [151°].— B'HHgCl_2 . [104°].— B'HgCl_2 . [204°]. Crystalline pp., sl. sol. water.

μ -Amido-thiazole $\text{N} \begin{smallmatrix} \text{C}(\text{NH}_2)\text{S} \\ \text{CH}=\text{CH} \end{smallmatrix}$ Thiazoline. Thiazylamine. (90°). Formed by the action of chloro-acetic aldehyde on thio-urea (Traumann, A. 249, 36). Prepared by boiling $\text{CH}_3\text{Cl}.\text{CHCl}.\text{OEt}$ (1 pt.) with thio-urea (1 pt.) and water (5 pts.). Yellowish plates, sl. sol. water, alcohol, and ether. Strong base.— B'HCl aq. Needles.— $\text{B'H}_2\text{PtCl}_4$. Yellow tables.

Acetyl derivative. [203°]. Needles.

THIAZOLE-TRIAZOLE (so called)

$\text{CH} \begin{smallmatrix} \text{S}=\text{C}:\text{N} \\ \text{CH.N.N} \end{smallmatrix} \text{CH}$. Formed by the action of HCl aq on methyl-nitroso-imido-thiazoline (Näf, A. 265, 123). Liquid, v. sol. water. Alkaline;

reduces Fehling's solution. Nitrous acid reproduces nitroso-methyl-imido-thiazoline.— B'HCl 2aq. [220°]. Needles.— B'HB'r 2aq.

THIENONE is DI-THIENYL KETONE.

DITHIENYL $\text{C}_6\text{H}_4\text{S}_2$ i.e. $\text{C}_6\text{H}_4.\text{S}.\text{C}_6\text{H}_4.\text{S}$. [83°]. (266° cor.). Formed on passing thiophene through a red-hot tube (Nahnsen, B. 17, 789, 2197). Plates (from alcohol). Conc. H_2SO_4 gives a reddish-brown solution with deep-green fluorescence. On warming with isatin and H_2SO_4 it gives a violet-blue colour.

Sulphonic acid $\text{C}_6\text{H}_3\text{S}_2(\text{SO}_3\text{H})$. Got by heating with H_2SO_4 (20 pts.) at 100°. Yields a crystalline BaA' aq.

Reference.—HEXA-BROMO-DITHIENYL.

THIENYL-ACETIC ACID $\text{C}_6\text{H}_4\text{S}.\text{CH}_2.\text{CO}_2\text{H}$. [76°]. Formed from $\text{C}_6\text{H}_4\text{S}.\text{CH}(\text{OH}).\text{CO}_2\text{H}$ [115°], HIAq , and P (Ernst, B. 19, 3281). Crystalline, sol. hot water, alcohol and ether.— BaA'_2 (dried at 130°). Crystals.— AgA' : pp.

Reference.—OXY-THIENYL-ACETIC ACID.

THIENYL-ACRYLIC ACID $\text{C}_6\text{H}_4\text{SO}_2$ i.e. $\text{C}_6\text{H}_4\text{S}.\text{CH}:\text{CH}.\text{CO}_2\text{H}$. [138°]. Formed by boiling thiophenic aldehyde with NaOAc and Ac_2O (Biedermann, B. 19, 1855). Needles (from water), sol. hot water and alcohol. FeCl_3 gives an amorphous orange pp.— AgA' : white pp.

THIENYLAMINE v. AMIDO-THIOPHENE.

THIENYL-BROMO-ETHANE v. BROMO-THIENYL-ETHANE.

THIENYL-BROMO-ETHYLENE v. BROMO-THIENYL-ETHYLENE.

THIENYL BROMO-METHYL KETONE

$\text{C}_6\text{H}_4\text{S}.\text{CO}.\text{CH}_2\text{Br}$. ω -Bromo-acetothienone. Formed by adding Br (2 at.) to thienyl methyl ketone (1 mol.) dissolved in CS_2 (Brunswig, B. 19, 2891). Pungent yellow oil, may be distilled *in vacuo*. V. sol. alcohol and ether. Solidified by cold. Alcoholic NH_3 forms a deep-blue colour. Oxidised to (a)-thiophenic acid [126.5°]. Aniline yields $\text{C}_6\text{H}_4\text{S}.\text{CO}.\text{CH}_2.\text{NHPh}$ [80°].

Thienyl di-bromo-methyl ketone

$\text{C}_6\text{H}_4\text{S}.\text{CO}.\text{CHBr}_2$. [c. 0°]. Formed from thienyl methyl ketone and Br. Pungent oil, almost insol. ligroin.

(β)-THIENYL-CARBINOL $\text{C}_6\text{H}_4\text{S}.\text{CH}_2.\text{OH}$. (207° cor.). Formed by shaking (β -thiophenic aldehyde with aqueous potash (Biedermann, B. 19, 639). Liquid. HCl forms $\text{C}_6\text{H}_4\text{S}.\text{CH}_2\text{Cl}$, a pungent oil boiling with partial decomposition at 175°.

THIENYL CHLORO-ETHANE v. CHLORO-THIENYL-ETHANE.

THIENYL-CHLORO-ETHYLENE v. CHLORO-THIENYL-ETHYLENE.

(a)-THIENYL CHLORO-METHYL KETONE

$\text{C}_6\text{H}_4\text{S}.\text{CO}.\text{CH}_2\text{Cl}$. [47°]. (259° cor.). Formed by chlorination of thienyl methyl ketone (Peter, B. 18, 539). Pungent white crystals. Yields (a)-thiophenic acid on oxidation.

THIENYL-ETHYL-AMINE $\text{C}_6\text{H}_4\text{NS}$ i.e.

$\text{C}_6\text{H}_4\text{S}.\text{OHMe}.\text{NH}_2$. (186°). Got by reducing the oxim of thienyl methyl ketone in alcoholic solution by adding sodium-amalgam and HOAc (Goldschmidt a. Schulthess, B. 20, 1700). Liquid, sol. water. Absorbs CO_2 from the air.— B'HOAc . Needles, v. e. sol. water.

Benzoyl derivative. [95°]. Needles.

THIENYL ETHYL KETONE $\text{C}_6\text{H}_4\text{S}.\text{CO}.\text{C}_2\text{H}_5$. Propiothienone. (228° cor.). Formed from propionyl chloride, thiophene, and AlCl_3 (Kreker,

B. 19, 677). Liquid. Hot conc. H_2SO_4 forms propionic and thiophene (α)-sulphonic acids. Chromic acid mixture yields (α)-thiophenic acid. Oxim $\text{C}_6\text{H}_4\text{S.COEt.NOH}$. [56°].

THIENYL DIETHYL PHOSPHINE

($\text{C}_6\text{H}_5\text{S}$) Pet_2 . (225°). Formed from thienyl-chloro-phosphine and ZnEt_2 in ether (Sachs, B. 25, 1517).

Ethyl-iodide ($\text{C}_6\text{H}_5\text{S}$) Pet_2I .

Methyl-iodide ($\text{C}_6\text{H}_5\text{S}$) Pet_2MeI . [122°].

White powder, v. sol. water insol. ether.

THIENYL-GLYCOLLIC ACID α . OXY-THIENYL-ACETIC ACID.

(α)-THIENYL-GLYOXYLIC ACID

$\text{C}_6\text{H}_5\text{SO}_2\text{aq}$ i.e. $\text{C}_6\text{H}_4\text{S.CO.CO}_2\text{H}$. [91°]. Formed by oxidising thienyl methyl ketone with alkaline KMnO_4 (Peter, B. 18, 537; Biedermann, B. 19, 637; Bradley, B. 19, 2115). Formed also, together with thiophene (α)-carboxylic acid, by oxidation of (α)-ethyl-thiophene by alkaline KMnO_4 . Crystals (containing aq, possibly as $\text{C}_6\text{H}_4\text{S.C(OH)}_2\text{CO}_2\text{H}$), v. sol. warm water. Melts at 59° when hydrated. May be extracted by ether from its aqueous solution. If a drop of crude benzene, followed by H_2SO_4 , be added to its solution in HOAc , a brown colour is formed, which on addition of more H_2SO_4 , passes through blue-green, green, violet, red, and bluish-violet to blue.

Reactions.—1. On heating it splits up into CO_2 and thiophenic aldehyde. —2. On heating with di-methyl-aniline and ZnCl_2 , it yields the leuco-base of a green dye $\text{C}_6\text{H}_4\text{S.CH(C}_6\text{H}_4\text{NMe}_2)_2$. —3. PCl_5 forms thiophenic chloride.

Salts. — BaA'_2 aq. Slender efflorescent needles, v. sol. water. — CaA'_2 2aq. — CuA'_2 2aq. — ZnA'_2 2aq. — AgA' aq: amorphous pp., probably $\text{C}_6\text{H}_4\text{S.C(OH)}_2\text{CO}_2\text{Ag}$.

Methyl ether MeA' . [28-5°].

Ethyl ether EtA' . (265° uncor.). Oil.

Amide $\text{C}_6\text{H}_4\text{S.CO.CO.NH}_2$. [88°]. Needles, almost insol. water, v. sol. alcohol and ether.

Oxim $\text{C}_6\text{H}_4\text{S.C(NOH).CO}_2\text{H}$. [146°]. (Hantzsch, B. 24, 48). Slender white needles. Exhibits Liebermann's reaction (Bradley, B. 19, 2119). — BaA'_2 1½aq. — AgA' : amorphous pp. — MeA' . [105°]. Converted by NaOMe and MeI into liquid $\text{C}_6\text{H}_4\text{S.C(NOMe).CO}_2\text{Me}$. — EtA' . [128°]. Needles.

Acetyl derivative of the oxim. [87°].

Phenyl-hydrazide

$\text{C}_6\text{H}_4\text{S.C(N}_2\text{HPh).CO}_2\text{H}$. [165°]. Deep-yellow needles (from ether).

Reference.—NITRO-THIENYL-GLYOXYLIC ACID.

THIENYL HEXYL KETONE $\text{C}_{11}\text{H}_{16}\text{SO}$ i.e. $\text{C}_6\text{H}_4\text{S.CO.C}_5\text{H}_{11}$. (304° cor.). Formed from thiophene, heptyl chloride, and AlCl_3 in ligroin (Schleicher, B. 19, 664). Yellow oil, yielding (α)-thiophenic acid on oxidation. Conc. H_2SO_4 forms thiophene (α)-sulphonic and heptoic acids.

Oxim [49°]. Crystals (from alcohol).

THIENYL-INDOLE $\text{C}_{12}\text{H}_9\text{NS}$ i.e.,

$\text{C}_6\text{H}_4\text{C}(\text{NH})\text{C}_6\text{H}_4\text{S}$. [162°]. Formed by heating the phenyl-hydrazide of thienyl methyl ketone with ZnCl_2 (Brunck, A. 272, 201). Light-yellow needles, insol. water, v. sol. ether, m. sol. alcohol. Colours pine-wood, moistened with HCl , bluish-violet. Yields $\text{C}_6\text{H}_4\text{Br}_2\text{NS}$ [278°] and $\text{C}_6\text{H}_4\text{CH(C}_6\text{H}_4\text{NS)}_2$ [245°]. — $\text{B'O}_2\text{C}_6\text{H}_4\text{N}_2\text{O}$. [187°]. Dark red plates, v. sol. alcohol.

Nitrosamine $\text{C}_{12}\text{H}_9\text{(NO)NS}$. [241°].

DI-THIENYL KETONE ($\text{C}_6\text{H}_4\text{S})_2\text{CO}$. [88°]. (826° uncor.). Formed from thiophene, COCl_2 , and AlCl_3 . Obtained also by distilling calcium α -thiophenate (Gattermann, B. 18, 3012). Needles or plates, sol. alcohol.

Phenyl-hydrazide [187°].

THIENYL MERCAPTAN ($\text{C}_6\text{H}_4\text{S})\text{SH}$. (166°).

Got by reducing thiophene (α)-sulphinic acid with zinc and HClAq (Biedermann, B. 19, 1616). Got also in small quantity from succinic acid and P_2S_5 (V. Meyer a. Neure, B. 20, 1757). Stinking oil, volatile with steam. — $\text{AgS.C}_6\text{H}_4\text{S}$.

Acetyl derivative ($\text{C}_6\text{H}_4\text{S})\text{SAC}$. (231°).

Methyl ether ($\text{C}_6\text{H}_4\text{S})\text{SMe}$. (186°).

DI-THIENYL METHANE $\text{C}_6\text{H}_4\text{S}_2$ i.e.,

$\text{CH}_2(\text{C}_6\text{H}_4\text{S})_2$. (267°). Got by adding H_2SO_4 to a solution of thiophene and methylal in HOAc (Peter, B. 17, 1345). Oil, smelling like oranges. Volatile with steam. Gives a red colour with isatin and H_2SO_4 .

(α)-THIENYL METHYL KETONE $\text{C}_6\text{H}_5\text{SO}$ i.e. $\text{C}_6\text{H}_4\text{S.CO.CH}_3$. *Acetothienone*. (213° cor.). S.G. $\frac{4}{4}$ 1.167. Formed from thiophene, AcCl , and AlCl_3 (Peter, B. 17, 2643; Biedermann, B. 19, 636; Bradley, B. 19, 2115). Formed also from $\text{C}_6\text{H}_5(\text{HgCl})\text{S}$ and AcCl (Volhard, A. 267, 178). Liquid, smelling like acetophenone. Gives a blue colour with isatin and H_2SO_4 . Oxidised by KMnO_4 to (α)-thienyl-glyoxylic and thiophenic acids. Mercuric chloride and NaOAc form the compound $(\text{CH}_3\text{CO.C}_6\text{H}_4\text{S})\text{HgCl}_2$ crystallising in white needles. Oxalic ether (1 mol.) and NaOEt give $\text{C}_6\text{H}_4\text{S.CO.CH}_3\text{CO.CO}_2\text{Et}$ [42°], which forms large yellow crystals, converted by boiling alcoholic hydroxylamine hydrochloride into the compound $\text{C}_6\text{H}_4\text{S.C}(\text{N}=\text{CH.C.CO}_2\text{Et})_2$ or

$\text{CO}_2\text{Et.C}(\text{N}=\text{CH.C}_6\text{H}_4\text{S})_2$ crystallising in colourless needles [48°] (Angeli, B. 24, 232).

Oxim $\text{C}_6\text{H}_4\text{S(NOH)}$. [112°].

Phenyl-hydrazide $\text{C}_6\text{H}_4\text{S(N}_2\text{HPh)}$. [96°].

Reference.—Bromo-, Chloro-, Iodo-, and Nitro-THIENYL METHYL KETONE.

THIENYL PHENYL - AMIDO - METHYL

KETONE $\text{C}_6\text{H}_4\text{S.CO.CH}_2\text{NPh}$. [80°]. Formed by mixing $\text{C}_6\text{H}_4\text{S.CO.CH}_2\text{Br}$ with aniline in alcohol (Brunswig, B. 19, 2892). Plates. Yields a nitrosamine $\text{C}_6\text{H}_4\text{S.CO.CH}_2\text{NPh(NO)}$ [81°], and acetyl derivative $\text{C}_6\text{H}_4\text{S.CO.CH}_2\text{NPhAc}$ [142°].

THIENYL PHENYL KETONE

$\text{C}_6\text{H}_4\text{S.CO.C}_6\text{H}_5$. [55°]. (c. 300°). Formed by the action of AlCl_3 on a mixture of thiophene and BzCl (Corney, B. 17, 790). Formed also by heating $\text{C}_6\text{H}_5(\text{HgCl})\text{S}$ with BzCl at 100° (Volhard, A. 267, 179). Long needles (from dilute alcohol), insol. water. Gives a blue colour on heating with isatin and H_2SO_4 . Yields thiophene and benzoic acid on heating with soda-lime.

Oxims $\text{C}_6\text{H}_4\text{S.CPh.NOH}$. Hydroxylamine forms two stereo-isomeric (?) oxims [98°] and [114°] (Hantzsch, B. 23, 2332; 24, 59).

THIENYL-PHENYL-METHANE

$\text{CH}_2\text{Ph.C}_6\text{H}_4\text{S}$. (265°). Formed by the action of H_2SO_4 on a mixture of thiophene and benzyl alcohol dissolved in HOAc (Peter, B. 17, 1346). Liquid with fruity smell, volatile with steam. Gives a red colour with isatin and H_2SO_4 .

Thienyl-di-phenyl-methane $\text{CHPh}_2\text{C}_6\text{H}_4\text{S}$. [68°]. (830°-840°). Formed from thiophene, di-phenyl-carbinol, and P_2O_5 (Levi, B. 19, 1624).

Plates (from alcohol) or needles (from ligroin), v. sol. HOAc, alcohol, and ether. Crystallises from cold benzene in needles $C_7H_7SC_6H_5$ [48°].

THIENYL ISOPROPYL KETONE

$C_6H_5S.CO.CHMe_2$. (232° cor.). Formed from isobutyryl chloride, thiophene, and $AlCl_3$ (Krekeler, *B.* 19, 675). Liquid. Yields (a)-thiophenic acid on oxidation. Fuming H_2SO_4 reacts with formation of the sulphonic acid $C_6H_4(SO_3H)S.CO.CHMe_2$, which yields the salts BaA'_2 , PbA'_2 , and is converted by phenyl-hydrazine into $C_6H_4(SO_3N_2H_4Ph)S.C(N_2HPh).CHMe_2$, crystallising from hot water in plates.

Oxim $C_6H_5S.C(NOH).CHMe_2$. [108°]. Pearly plates (from dilute alcohol).

THIENYL STYRYL KETONE v. STYRYL THIENYL KETONE.

THIENYL DISULPHIDE $(C_6H_5S)_2S_2$. [56°].

Formed by atmospheric oxidation of a solution of thienyl mercaptan in alcoholic NH_3 (Meyer a. Neure, *B.* 20, 1757). Needles.

THIENYL SULPHOCYANO - METHYL KETONE $CH_3(SCy).CO.C_6H_5S$. [88°]. Formed from $CH_3Br.CO.C_6H_5S$ and $KSCy$ in alcohol (Brunswig, *B.* 19, 2893). Plates (from ether), sl. sol. water and ligroin, m. sol. alcohol.

DI-THIENYL-THIOPHENE $C_6SH_4(C_6SH_5)_2$. [147°]. (357°). V.D. 8.6. One of the products of the passage of benzene and sulphur-vapour through a red-hot tube (Renard, *C. R.* 112, 49). Yellowish needles (from alcohol), m. sol. benzene. H_2SO_4 forms a rose-coloured solution, turned violet and finally blue on heating. Fuming H_2SO_4 at 120° forms a trisulphonic acid, which yields $(C_6H_5S_2(SO_3)_3)_2Ca_3$ as an amorphous powder, v. sol. water. Fuming HNO_3 at 160° forms $C_{12}H_8S_3O_4$ [318°], crystallising in white plates, v. sl. sol. benzene. Br forms $C_{12}H_8Br_3S_3$ [282°], and amorphous $C_{12}H_8Br_3S_3$.

THIENYL TOLYL KETONE $C_{12}H_{10}SO$ i.e. $C_6H_5Me.CO.C_6H_5S$. Formed from *o*-toluic chloride, thiophene, and $AlCl_3$ (Ernst, *B.* 19, 3279). Oil. Yields an oily oxim.

THIO-. This prefix is employed to denote the replacement of O by S. Most inorganic salts of thio-acids are described under the heading of the oxy-salts; thus *thio-carbonates* are described under CARBONATES. In some cases thio-salts are described under the heading of the characteristic element of the salts: *thio-arsenates* are to be found under ARSENIC. Certain thio-salts are described under headings placed in their strictly alphabetical position; for instance, THIOSULPHATES. *Thiocyanides* are described as SULPHOCYANIDES.

The following addition should be made to the sub-article THIO-OXYORTHOPHOSPHATES (p. 147). By heating metallic chlorides or sulphides with excess of P_2S_5 , Glatzel has prepared a number of *tetrathio-oxyorthophosphates*, i.e. salts of the hypothetical acid H_4PS_4 (*Zeit. für anorg. Chemie*, 4, 186). These salts are crystalline—generally green to black in colour; they are burnt in air, giving off SO_2 ; some are decomposed to sulphides and P_2S_5 , but the mercuric and arsenic salts distil unchanged when heated out of contact with air. These salts are insol. in dilute acids; they are decomposed by strong acids. G. isolated the thiophosphates of Sb, As, Bi, Cd, Cu(ous), Fe(ous), Pb, Mn, Hg(io), Ni, Ag, Tl, Sn(ous), and Zn; he could not obtain the salts of Ca, K, Na, or Sr.

M. P. M.

THIOACETAMIDE $CH_3CS.NH_2$. [108°].

Formed from acetonitrile and H_2S (Bernthsen, *A.* 192, 46), and from acetamide and P_2S_5 (Hofmann, *B.* 11, 340). Monoclinic plates, v. sol. water and alcohol, m. sol. ether. HgO forms HgS . $AgNO_3$ gives Ag_2S . $CuSO_4$ and $Pb(OAc)_2$ give, on boiling, CuS and PbS . $HgCl_2$ forms a crystalline compound. ω -bromo-acetoacetic ether forms $CH_2C(NH).S.CH_2.CO.CH_2.CO_2Et$ [94°], and finally $S < CH.CO.CH_2.CO_2Et$ (239°), the ether of methyl-thiazyl-acetic acid [121°] (Steude, *A.* 261, 36). The ether melting at 94° is converted by warming with water into the compound $CH_2.CO.S.CH_2.CO.CH_2.CO_2Et$ (155° at 15 mm.), whence H_2SO_4 forms an acid $C_6H_5SO_2$ [168°].

THIO-ACETIC ACID C_2H_3SO i.e. $CH_3.CO.SH$. Mol. w. 76. (93°). S.G. 1.074. Prepared by distilling acetic acid with P_2S_5 (Kekulé, *A.* 90, 311; Ulrich, *A.* 109, 272; Kekulé a. Linne-mann, *A.* 123, 273). Obtained also from $AcCl$ and KSH (Jacquemin a. Vosselmann, *J.* 1859, 354), by heating lead acetate with $Na_2S_2O_3$ (Fröhde, *Z.* 1866, 543), and by the action of KSH on an alcoholic solution of $PhSAc$ (Kekulé, *Z.* [2] 3, 196). Colourless liquid, turning yellow on keeping. Smells like acetic acid and H_2S . Not solid at -17° . M. sol. warm water, v. sol. alcohol and ether. Violently attacked by fuming HNO_3 . PCl_5 yields $AcCl$, $PSCl_2$, and HCl . Its neutral solutions give pps. with $AgNO_3$ and $HgCl_2$, which quickly turn black. Molten $ZnCl_2$ forms CMe_2S_2CMe [225°], which may be crystallised from hot alcohol (Bongartz, *B.* 19, 2182). HCl passed into a mixture of thio-acetic acid and benzoic aldehyde forms $(CH_3.CO.S)_2CHPh$ [148°], crystallising from hot ether in slender needles.

Salts.— KA' . Crystals, v. sol. water and alcohol.— NaA' 1 aq.— BaA'_2 3 aq.— SrA'_2 2 aq.— CaA'_2 2 aq.— PbA'_2 . Silky needles (from hot water or alcohol). Quickly decomposes, with separation of PbS .

Methyl ether MeA' . (96°). Formed by heating $AcBr$ with Me_2S at 100° (Cahours, *Bl.* 25, 562; Wallach a. Bleibtreu, *B.* 12, 1062). Formed also from $AcCl$ and $Pb(SMe)_2$ (Obermeyer, *B.* 20, 2920).

Ethyl ether EtA' . (116° i.v.). Formed from $AcCl$ and $NaSEt$ (Saytzeff, *Z.* [2] 4, 642; Beckmann, *J. pr.* [2] 17, 461). Formed also from $PhOAc$ and $NaSEt$ (Seiffert, *J. pr.* [2] 31, 468). Colourless liquid, with alliaceous odour. Oxidised by $AgMnO_4$ to acetic acid and ethane sulphonic acid.

n-Propyl ether PrA' . (136°).

Isopropyl ether PrA' . (126°).

Isobutyl ether CH_3PrA' . (149°).

Anhydride v. ACETYL SULPHIDE.

Thio-acetic acid $CH_3CS.OH$.

Amide v. THIOACETAMIDE.

Anilide $CH_3CS.NHPh$. [75°]. Formed from $CH_3CCl.NPh$ and H_2S (Leo, *B.* 10, 2134). Prepared by heating acetanilide with P_2S_5 at 100° (Hofmann, *B.* 11, 339; Jacobsen, *B.* 19, 1071). Yellowish needles (from water). Sol. $NaOHAq$ and reppd. by acids. On oxidation with alkaline K_2FeO_4 , it yields ethenyl-amidophenyl mercaptan. MeI forms C_6H_5NSMeI or $(CH_3CS.NPhMe)HI$ [139°], which yields an aqueous solution from which $AgNO_3$ at once

ppts. AgI, and which is converted by AgCl into $C_6H_5NSMeCl$, whence $(C_6H_5NSMeCl)_2PtCl_4$ may be got (Bernthsen, A. 192, 56). NaOEt forms $CH_3C(SNa)NPh$, whence MeI yields the ether $CH_3C(SMe)NPh$ (245°) (Wallach a. Bleibtreu, B. 12, 1061; 13, 529), which is decomposed by MeI at 100° into methyl thioacetate and methyl-aniline. NaOEt and EtBr yield the corresponding $CH_3C(SET)NPh$, a heavy oil, insol. alkalis, split up by warm HClAq into thioacetic ether and aniline. 'Ethyl-iso-thioacetanilide' yields $(C_6H_5NS)_2H_2PtCl_4$.

Methyl antilide $CH_3CS.NMePh$. [59°]. (290°). Formed from AcNMePh and P_2S_5 (Wallach, B. 13, 528). Monoclinic tables, v. sol. alcohol.

o-Toluide $CH_3CS.NHC_6H_4$. [68°]. Yields $CH_3C(SET).NO_2C_6H_4Me$ (262°), an oil which reacts with bases forming amidines and EtSH.

p-Toluide [132°]. Yields oily $CH_3C(SET).NO_2C_6H_4$. (273°) (Wallach a. Wüsten, B. 16, 147).

Xylidide $CH_3CS.NHC_6H_4Me_2$. [80°] (G.); [95°] (Jacobsen). Formed by heating acetyl-xylidine with P_2S_5 on the water-bath (Gudeman, B. 21, 2561).

ψ-Cumidide $CH_3CS.NHC_6H_4Me_2$. [114°]. Prisms (Jacobsen a. Elley, B. 22, 907).

(a)-**Naphthalide** $CH_3CS.NHC_{10}H_7$. [96°]. Tables. Formed from naphthyl-acetamidine and CS_2 (Bernthsen a. Trompeter, B. 11, 1760).

(β)-**Naphthalide**. [146°]. Needles or plates (Jacobsen, B. 21, 2627). Oxidised by K_2FeO_4

to $C_{10}H_6\langle\frac{N}{S}\rangle CMe$ [81°].

Tri-thio-ortho-acetic acid $CH_3C(SH)_3$.

Ethyl ether $CH_3C(SET)_3$. Formed from mercaptan, $CHCl_3$, and NaOH at 100° (Laves, B. 25, 354). Brownish liquid. Oxidised by $KMnO_4$ and H_2SO_4 to the trisulphone.

Benzyl ether $CH_3C(SC_6H_5)_3$. [46°]. Formed from benzyl mercaptan, $CHCl_3$, and (2 p.c.) NaOHAg (Laves). Crystals, v. sol. $CHCl_3$, m. sol. alcohol.

THIO-ACETIC ALDEHYDE. On passing H_2S into an aqueous solution of aldehyde, crude thioacetic aldehyde separates as an oil, which solidifies at -8°, and then melts at -2°. This oil (V.D. 60 (H=1)) is a mixture of thioacetic aldehyde and its polymerides, and may be represented, in a state of vapour, as $C_2H_4S + C_6H_{12}S_3$ (Pinner, B. 4, 258; Klinger, B. 9, 1893; 10, 1877; 11, 1023). On distillation, or on passing HCl through the liquid, it is converted into the polymeric tri-thio-tri-acetic aldehyde.

Tri-thio-tri-acetic aldehyde $C_6H_{12}S_3$. Mol. w. 180. [46°]. V.D. 89.7 (calc. 90) (Hofmann, B. 3, 589; Z. [2] 6, 699). Formed by passing H_2S into an acid solution of aldehyde (Klinger; cf. Weidenbusch, A. 66, 152; Crafts, C. R. 54, 1279). Formed also from paraldehyde and H_2S . White needles, sol. alcohol and ether. Smells like garlic. $AgNO_3$ added to its alcoholic solution forms crystalline $C_6H_{12}S_3.2AgNO_3$. Chlorine forms ethylidene chloride (Pinner, A. 179, 21). $KMnO_4$ oxidises it to $CH_3CH(SO_3H)_2$ and oxysulphides, including $C_6H_{12}S_3O_2$ [217°], which crystallises from hot water in needles (Guareschi, A. 222, 301). Zinc permanganate produces $C_6H_{12}S_3O_2$, which does not melt below

245°, $C_6H_{12}S_3O_2$ [112°-116°], and $C_6H_{12}S_3O_4$ [228°-231°] (cf. Baumann, B. 26, 2074).

(a)-**Tri-thio-tri-acetic aldehyde** $C_6H_{12}S_3$, i.e. $CHMe\langle S.CHMe\rangle S$. [102°]. (247°). V.D. 6

(air=1). Formed by the long-continued action of H_2S on a mixture of equal parts of water, conc. HClAq and aldehyde. Long prisms (from acetone). Reduced by HI to Et_2S_2 . Oxidised by $KMnO_4$ to $C_6H_{12}S_3O_4$ [284°] (S. 1 at 100°; 116 at 20°), and $C_6H_{12}S_3O_6$ or $C_6H_4\langle SO_2.C_2H_4\rangle SO_2$, which softens at 340° and is converted by MeI into $C_6H_4S_3O_6$ [302°]. Yields crystalline $C_6H_{12}S_3AgNO_3$ and $C_6H_{12}S_3.8AgNO_3$.

(β)-**Tri-thio-tri-acetic aldehyde** $C_6H_{12}S_3$. [126°]. (247°). V.D. 6.0. Formed by the action of $AcCl$ or H_2SO_4 on its (a)-isomeride. Prepared by passing H_2S into a mixture of aldehyde (1 pt.) and alcohol previously saturated with HCl (3 pts.) (Baumann a. Fromm, B. 22, 2600; 26, 2074). Long needles (from alcohol). Oxidised by $KMnO_4$ to the same sulphones as the (a)-isomeride. Reacts with MeI, yielding SMe_2I . Distillation with Cu forms ψ-butylene. Forms crystalline $C_6H_{12}S_3AgNO_3$ and $C_6H_{12}S_3.8AgNO_3$.

(γ)-**Tri-thio-acetic aldehyde** $C_6H_{12}S_3$. [76°]. (242°). Formed, together with $C_6H_5NS_3$, by boiling thialdine sulphocyanide with water (Marckwald, B. 19, 1827; 20, 2817). Needles (from alcohol), insol. water, v. sol. ether and CS_2 . Volatile with steam. Sol. conc. H_2SO_4 and reppd. by water. When mixed with EtI (4 pts.) and left for some weeks it suddenly changes to a crystalline mass of the (β)-isomeride. $C_6H_{12}S_3AgNO_3$. Plates, v. sol. water. Yields Ag_2S on boiling with alcohol.

'Di-thialdehyde thiocarbimide' $C_6H_5NS_3$. [138°]. Formed as above. Needles, m. sol. ether. Yields $C_6H_5NS_3AgNO_3$, v. sol. water, and $(C_6H_5NS)_2PtCl_4$.

Di-thio-acetic orthoaldehyde. **Ethyl ether** $CH_3CH(SET)_2$. Formed by passing HCl into a mixture of acetic aldehyde and EtSH (Baumann, B. 18, 884). Mobile oil.

THIOACETIC ANHYDRIDE v. ACETYL SULPHIDE.

THIO-ACETONE $*CH_3CS.CH_3$. A product of the action of H_2S on acetone, and formed also when $CMe_2(SET)_2$ is heated above 160° (Baumann a. Fromm, B. 22, 2592). Volatile oil, with very persistent and disagreeable smell. Unstable.

Duplo-thioacetone $C_6H_{12}S_2$, i.e. $S\langle CMe_2\rangle S$.

V.D. 5.08 (calc. 5.11). (154° cor.). Formed by heating acetone with P_2S_5 at 125° (Wislicenus, Z. [2] 5, 324; Autenrieth, B. 20, 375). Formed also by heating tri-thio-tri-acetone at 200° for some time (Fromm a. Baumann, B. 22, 1043). Oil. Its alcoholic solution gives a white pp. with $HgCl_2$. Reduced by sodium-amalgam to isopropyl mercaptan (Spring, Bl. [2] 40, 69). Oxidised by a 5 p.c. solution of $KMnO_4$ to the disulphone $SO_2\langle CMe_2\rangle SO_2$ [220°-225°].

Tri-thio-tri-acetone $C_6H_{12}S_3$, i.e. $S\langle CMe_2\rangle S.CMe_2$. [24°]. (180° at 15 mm.). Formed, together with $C_6H_5NS_3$ [171°], by passing H_2S into a cooled mixture of acetone and

conc. HClAq (Fromm a. Baumann, *B.* 22, 1037, 2597). Needles (from alcohol); insol. water, v. sol. alcohol and ether. Boils, with much decomposition, at 225°-230°. Gives a white pp. with HgCl₂ and a yellow pp. with lead acetate. Potassium permanganate and H₂SO₄ yield the trisulphone SO₂<CMe₂.SO₂>CMe₂ [302°] and

Duplo-di-thio-acetone (Me₂CS₂)₂. [98°]. (c. 243°). Formed from acetone and yellow ammonium sulphide in the cold (Willgerodt, *B.* 20, 2467). Dimetric crystals, *a:c* = 1:868, insol. water. Partially decomposed on distillation.

Di-thio-orthacetone. *Di-ethyl ether* CMe₂(SEt)₂. *Acetone-ethyl-mercaptol*. (191°). Formed by passing dry HCl into a mixture of acetone (1 pt.) and mercaptan (2 pts.) (Baumann, *B.* 18, 887). Liquid.

Di-phenyl ether CMe₂(SPh)₂; v. **DI-PHENYL-PROPYLDENE DISULPHIDE**.

THIOACETONURAMIC ACID v. **ACETONYL THIOCARBAMATE**.

THIO - ACETOPHENONE C₆H₅.CS.CH₃. [119.5°]. Formed by the action of alcoholic ammonium sulphide on acetophenone (Engler, *B.* 11, 930). Colourless leaflets or needles, insol. water, sl. sol. alcohol, v. sol. ether. May be sublimed.

THIO-ACETYL-TOLUIDINE v. *Toluide of THIO-ACETIC ACID*.

THIO-ALLOPHANIC ACID. *Ethyl ether* C₂H₅N₂SO₂ i.e. NH₂.CO.NH.CO.SET. [180°]. Formed by heating urea with Cl.CO.SET at 80°-90° (Peitzsch a. Salomon, *J. pr.* [2] 7, 477). Pearly needles (from water), v. sl. sol. cold water and alcohol. Aqueous NH₃ at 100° forms biuret and mercaptan. Boiling baryta-water gives allophanic acid and mercaptan. Aniline yields di-phenyl-biuret and mercaptan.

Isoamyl ether NH₂.CO.NH.CO.SC₄H₁₁. [176°]. Needles (Schöne, *J. pr.* [2] 32, 251). AcCl yields an acetyl derivative [85°].

Phenyl ether [218°] (Gattermann, *A.* 244, 43).

Isothio-allophanic ether NH₂.CS.NH.CO₂Et. [170°-175°]. Formed by the action of thio-urea on COCl.CO₂Et (Peitzsch, *B.* 7, 896). Prisms (from alcohol).

Di-thio-allophanic ether NH₂.CS.NH.CO.SET. Formed from KSCy, alcohol, and HCl (Blankenhorn, *J. pr.* [2] 16, 358). Pearly prisms, insol. cold water, sol. hot ether. Alcoholic NH₃ at 150° forms thio-urea. Baryta-water yields mercaptan, CO₂, and thio-urea.

DI-THIO-AMMELIDE C₂H₄N₂S₂ i.e. C₂N₂(NH₂)(SH)₂. S. 3 at 100°. Formed by boiling pseudosulphocyanogen C₂H₂N₂S₂ with KSH or ammonium sulphide solution (Jamieson, *A.* 59, 339; Ponomareff, *J. R.* 8, 222). Small needles, nearly insol. cold water, alcohol and ether, v. sol. aqueous ammonium sulphocyanide. Acid in reaction, decomposing carbonates.

Reactions.—1. Yields cyanuric acid when heated with HClAq. —2. NH₃Aq forms melamine C₂H₄N₆ by heating in a sealed tube.

Salts.—NaHA' 1½ aq. Tables.—KHA' 2aq. White prisms, v. e. sol. water and alcohol.—MgH₂A' 6aq.—CaH₂A' 2aq.—BaH₂A' 5aq.—BaH₂A' 6aq. Monoclinic crystals, sl. sol. cold

water.—SrH₂A' 4aq.—AgHA'. Flocculent pp., insol. water.

Methyl ether C₂N₂(NH₂)(SMe)₂. [200°]. Formed by heating C₂N₂(SMe)₂ with alcoholic NH₃ for five hours at 100° (Hofmann, *B.* 18, 2756). Trimetric tables, v. sl. sol. water, v. sol. alcohol. Boiling conc. HClAq forms MeSH, cyanuric acid, and NH₃.—B'H₂AuCl₄. Needles.

Ethyl ether Et₂A'. [112°]. Formed by heating tri-thio-cyanuric ether with alcohol NH₃ at 180° (Klason, *J. pr.* [2] 33, 298). Trimetric prisms. Converted by acids into ammeline.

Isoamylether (C₅H₁₁)₂A'. [82°].

Di - thio - methyl ammeline di - methyl ether Cy₂(NHMe)(SMe)₂. [175°]. Formed by heating Cy₂(SMe)₂ with aqueous NMeH₂ (Hofmann, *B.* 18, 2761). Needles or prisms (from dilute alcohol).

THIO-AMMELINE C₂H₄N₂S i.e.

Formed by adding HCl to an aqueous solution of dicyan-diamide and ammonium sulphocyanide at 100° (Rathke, *B.* 18, 3106; 20, 1059; 23, 1675). Formed also from C₂N₂(NH₂)₂Cl and KSH (Klason, *J. pr.* [2] 33, 296) and by heating ψ-sulphocyanogen with conc. NH₃Aq at 100° (Ponomareff, *C. R.* 80, 1884). Needles, sl. sol. hot water, v. sol. acids and alkalis. Yields a canary-yellow pp. on boiling with ammoniacal CuSO₄. Conc. HClAq at 130° yields cyanuric acid, H₂S, and NH₃. Ethylenebromide forms crystalline C₂H₄N₂SHBr. Conc. NH₃Aq at 200° forms melamine. Boiling NaOHAq yields ammeline. Ammoniacal silver nitrate ppts. C₂H₄N₂SAg and C₂H₄N₂SAg₂. Bromine added to a solution of thio-ammeline in HBrAq forms S₂(C₂N₂(NH₂)₂)₂, which dissolves in alkalis, is split up by boiling with acids into ammeline, thio-ammeline, and S.

Salts.—B'HNO₃. Needles.—B'₂H₂SO₃ 3aq.—B'₂H₂C₂O₄. Needles, v. sl. sol. cold water.

Methyl ether MeA'. [268°]. Formed by heating tri-methyl tri-thiocyanurate for five hours with conc. alcoholic NH₃ at 160° (Hofmann, *B.* 18, 2757). Tables (from water).—B'₂H₂PtCl₆.

Ethyl ether EtA'. [165°].

Isoamyl ether C₅H₁₁A'. [178°].

Reference.—**TRI-PHENYL-THIO-AMMELINE**.

THIO-ANILINE v. **DI-AMIDO-DI-PHENYL SULPHIDE**.

THIOANISOIC ACID (so called) C₇H₇SO₂. Got by boiling anethol with HNO₃ (S.G. 1.1), distilling the product and shaking the fraction 215°-245° with conc. NaHSO₄Aq and some alcohol (Städeler a. Wächter, *A.* 116, 163). Crystalline (containing 2aq), v. e. sol. water, alcohol, and ether.—NH₄A'aq.—NaA'aq. S. 15 in the cold.—BaA'₂ 3aq. S. 8.5 in the cold.—CaA'₂ 2aq.—MgA'₂ 5aq.—AgA'. Plates, m. sol. water.

THIOBENZAMIDE v. *Amide of THIOBENZOIC ACID*.

(α)-**THIO-BENZOIC ACID** C₆H₅.CO.SH. Mol w. 138. [c. 24°].

Formation.—1. From BzCl and alcoholic K₂S (Engelhardt a. Latschinoff, *Z.* [2] 4, 358).—2. By boiling EtOBz, PhOBz, and Bz₂O with alcoholic KSH.

Properties.—Yellow oil or white crystalline mass with unpleasant smell, volatile with steam. Decomposed by distillation. V. sol. alcohol and

ether. Its solutions, when exposed to air, deposit crystals of Bz_2S_2 . Nitric acid also oxidises it to benzoyl disulphide. A neutral solution gives with $CuSO_4$ a greenish-yellow pp., turning bright red; the pp. then containing Bz_2S_2 .

Salts.— KA' . Large prisms (from alcohol), v. sol. water.— NaA' .— BaA'_2 aq. Laminæ (from alcohol).— PbA'_2 .— AgA' . Yellowish-white pp.

Methyl ether $C_6H_5.COSMe$. (232°). Formed from $Pb(SMe)_2$ and $BzCl$ (Obermeyer, *B.* 20, 2922).

Ethyl ether EtA' . (243°). Formed by the action of $BzCl$ on $Pb(SET)_2$ in presence of ether (Titschett, *Petersb. Acad. Bull.* 5, 295), and got also by boiling AgA' and EtI , and from $PhOBz$ and $NaSEt$ (Seiffert, *J. pr.* [2] 31, 471). Oil, with unpleasant smell, sol. alcohol and ether. Boiling alcoholic KOH forms KOBz and KSEt. Alcoholic KSH yields KSBz and KSEt. Oxidised by $AgMnO_2$ to benzoic and ethane sulphonic acids (Beckmann, *J. pr.* [2] 17, 464).

Isoamyl ether $C_5H_{11}A'$. (271°).

Phenyl ether $PhS.Bz$. [56°]. Formed from phenyl mercaptan and $BzCl$ (Schiller a. Otto, *B.* 9, 1635). Needles (from benzene).

Di-nitro-phenyl ether $C_6H_3(NO_2)_2A'$. [118°]. Formed from (a)-chloro-*m*-di-nitrobenzene, alcoholic KSH, and $BzCl$ (Willgerodt, *B.* 18, 328). Needles (from alcohol).

Benzyl ether C_6H_5A' . [39-5°]. Formed from benzyl mercaptan and $BzCl$ (Otto a. Liders, *B.* 13, 1285). Triclinic crystals, yielding $PhCH_2.SO_2H$ on oxidation.

p-Tolyl ether C_6H_4A' . [75°] (S. a. O.).

Anhydride v. BENZOYL SULPHIDE.

(*B*). Thio-benzoic acid $C_6H_4.CS.OH$. Formed by boiling thiobenzoic aldehyde with nitric acid (S.G. 1.3) (Fleischer, *A.* 140, 234). Needles (containing $\frac{1}{2}$ aq.), sol. alcohol and benzene. More sol. hot water than benzoic acid. When heated strongly it blackens without melting.— BaA'_2 aq. Small nodules, v. sol. water and ppd. by alcohol.

Amide $C_6H_5.CS.NH_2$. *Thiobenzamide*. [116°]. Formed by passing H_2S into an alcoholic solution of benzonitrile containing a little NH_3 , and heating on a water-bath (Cahours, *C. R.* 27, 329; Bernthsen, *B.* 10, 1241; A. 192, 49; Gabriel a. Heymann, *B.* 23, 157). Formed also by heating benzylamine (2 mols.) with S (1 mol.) at 180° (Wallach, A. 259, 304). Long needles (from hot water). Decomposed by HgO , yielding HgS and benzonitrile. Sodium-amalgam acting on its alcoholic solution forms amorphous thiobenzoic aldehyde, benzonitrile, benzylamine, and benzoic aldehyde. Iodine added to its alcoholic solution reacts with formation of di-benzenyl-azo-sulphim

$C_6H_5.C \begin{smallmatrix} N \\ \diagup \end{smallmatrix} \begin{smallmatrix} S \\ \diagdown \end{smallmatrix} C_6H_5$, crystallising in long

colourless needles [90°] converted by boiling H_2SO_4 into a base $O_2H_4.N_2$ [71°], which yields $B'H.PtCl_4$ (Hofmann, *B.* 2, 645; B. 25, 1587; Wanstrat, *B.* 6, 335). Zinc and HCl reduce thiobenzoic aldehyde in alcoholic solution to benzylamine. Hydroxylamine forms $C_6H_5.C(NO_2H).NH_2$. Ethylene bromide at 100° forms the compound $C_6H_5.(S.C(NH)C_6H_5)_2.HBr$ [238°] decomposed by boiling water into $C_6H_5.(SBz)_2$ (Gabriel a. Heymann, *B.* 24, 783). Chloral (1 mol.) forms, on warming, a compound $C_6H_5Cl.NSO$ or $C_6H_5.CS.NH.CH(OH).OCl$, (?) crystallising in

silky plates [104°], sl. sol. water, v. sol. alcohol (Spica, *G.* 16, 182).

Anilide $C_6H_5.CS.NHPh$ or $C_6H_5.C(SH):NPh$. *Thiobenzanilide*. [102°]. Formed by the action of P_2S_5 (1 pt.) on benzaniline (2 pts.), and by heating phenyl-benzamide or *s*-di-phenyl-benzamide $OPh(NPh)(NPhH)$ with H_2S or with CS_2 (Bernthsen, *B.* 11, 503; A. 192, 31). Formed also by passing H_2S into a solution of $C_6H_5.CCl:NPh$ in benzene (Leo, *B.* 10, 2133), and from benzophenone oxim and P_2S_5 (Dodge, A. 264, 184). Obtained by heating benzyl-aniline (1 mol.) with S (2 at.) at 220° as long as H_2S escapes (Wallach, A. 259, 301). Thin prisms (from $EtOAc$), nearly insol. boiling water, v. sol. alcohol and ether. V. sol. KOHAq. Converted into benzaniline by heating with dry PbO or with alcoholic potash at 150°. Yields benzenyl-*o*-amido-phenyl-mercaptan on dry distillation, on heating with S, and also on treatment in alkaline solution with K_2FeCy_6 (Jacobsen, *B.* 19, 1068). Hydroxylamine yields $C_6H_5.C(NO_2H).NHPh$.

o-Toluide $C_6H_4.CS.NHC_6H_4Me$ [1.2]. [86°]. Formed by melting $BzNH.C_6H_4Me$ with P_2S_5 (Stieglitz, *B.* 22, 3160). Yellow, six-sided prisms (from benzene). Hydroxylamine in alcohol forms, on heating, $C_6H_4.C(NO_2H).NHC_6H_4$, [147°], crystallising in needles.

p-Toluide. [129°]. Formed in like manner (Müller, *B.* 22, 2405), and also by the action of H_2S on $C_6H_4.CCl:NC_6H_4$ (Leo, *B.* 10, 2134; Pätzinger a. Gattermann, *B.* 22, 1065), and by heating *p*-tolyl-benzamide with CS_2 (Bernthsen a. Trompeter, *B.* 11, 1759). Long yellow needles, insol. water, v. sol. alcohol, ether, and NaOHAg.

Xylide $C_6H_4.CS.NHC_6H_4Me_2$. [90°]. Formed by heating the benzoyl derivative of (4,2,1)-xylidine with P_2S_5 (Gudeman, *B.* 21, 2552). Small needles (from alcohol). Oxidised by

K_2FeCy_6 to oily $C_6H_2Me_2 \begin{smallmatrix} N \\ \diagup \end{smallmatrix} \begin{smallmatrix} S \\ \diagdown \end{smallmatrix} C_6H_5$.

Di-phenyl-amide $C_6H_5.CS.NPh_2$. [151°]. Triclinic crystals (Bernthsen, A. 192, 37).

(*a*) *Naphthalide* v. vol. iii. p. 474.

Di-thio-benzoic acid $C_6H_4.CS.SH$. Formed by adding an alcoholic solution of K_2S to $C_6H_5.CCl$, (Engelhardt a. Latschinoff, *Z.* [2] 4, 455; Klinger, *B.* 15, 862). Heavy, red oil, v. sol. alcohol and ether. Its dilute ethereal solution is crimson. Resinifies when exposed to air.— PbA'_2 . Thin orange-red needles (from alcohol or xylene).— HgA'_2 . Golden plates (from alcohol).— AgA' . Brown pp., insol. water and benzene.

References.—OXY-THIO-BENZOIC ACID and AMIDO-THIO-BENZAMIDE.

(*a*) THIO-BENZOIC ALDEHYDE $C_6H_5.CHS$. *Benzylidene sulphide*. Formed by passing H_2S into an alcoholic solution of benzoic aldehyde (Laurent, A. *Ch.* [3] 1, 292; Klinger, *B.* 9, 1895; 15, 863; Böttinger, *B.* 12, 1056), or of hydrobenzamide (Cahours, *C. R.* 25, 457). White amorphous powder, softening at 85°, decomposed at a higher temperature. Insol. water and cold alcohol, v. e. sol. benzene and chloroform. Does not combine with $KHSO_4$ or HCl . Potash-fusion yields benzyl mercaptan. On heating with copper it forms CuS and *s*-di-phenyl-ethylene. Alcoholic KSH on heating forms $Ph.CS.SK$ and di-benzyl disulphide. Thiogly-

collic acid forms $C_6H_5.CH(S.OH_2.CO_2H)_2$ [124°] (Bongartz, B. 21, 479).

(β)-Thio-benzoic aldehyde $(C_6H_5.OHS)_2$ [225°]. Formed from the (α)-isomeride by treatment with $AcCl$, EtI , or a little iodine in benzene (Klinger, B. 10, 1877). Prepared by passing H_2S into a mixture of benzoic aldehyde and alcoholic HCl (Baumann a. Fromm, B. 22, 2604). Needles. Crystallises from benzene as $(C_6H_5)_2C_2H_4$, and gives off its benzene at 180°-140°. V. sol. hot $HOAc$, m. sol. alcohol. On heating with copper-powder it yields CuS and di-phenyl-ethylene. An oily compound $(C_6H_5)_2H_2S$ is formed, together with benzyl disulphide and di-thio-benzoic acid, by the action of alcoholic KSH on benzylidene chloride (Klinger, B. 15, 864). This compound yields benzoic acid on treatment with dilute HNO_3 .

(γ)-Thio-benzoic aldehyde $C_6H_5.OHS$. [167°]. Occurs in the benzene mother-liquor in the preparation of the (β)-isomeride (B. a. F.). Small pointed needles, much more sol. benzene and chloroform than the (β)-modification, sl. sol. alcohol and ether. Its crystals do not contain benzene of crystallisation. By adding iodine to its solution in benzene it is changed to the (β)-isomeride.

Thio-benzoic orthaldehyde $C_6H_5.CH(SH)_2$.

Methyl ether $C_6H_5.CH(SMe)_2$. Formed by passing HCl into a mixture of benzoic aldehyde and $MeSH$ (Bongartz, B. 21, 487). Oil. Oxidised by $KMnO_4$ to $C_6H_5.CH(SO_2CH_3)_2$ [163°].

Ethyl ether $C_6H_5.CH(SeEt)_2$. Oil (Baumann, B. 18, 885).

p-Bromophenyl ether

$C_6H_4.CH(SC_6H_4Br)_2$. [80°]. Silky needles (Baumann, B. 18, 885).

Reference.—NITRO-THIO-BENZOIC ALDEHYDE.

THIO-BENZOPHENONE $C_6H_5.CS.C_6H_5$.

Formed by heating $CSCl_2$ (5g.) with benzene (25 g.) and $AlCl_3$ (9 g.) (Bergreen, B. 21, 337). Reddish-brown oil, v. sol. ether, benzene, and hot alcohol. Decomposed by distillation. Reacts with hydroxylamine, forming $Ph_2C:NOH$ and with phenyl-hydrazine, with production of $CPh_2.N_2HPh$.

Thio-benzophenone $(CSPPh)_2$. [146°-5°].

Formed from CCl_4Ph and K_2S (Engler, B. 11, 922). Small white needles. Converted by CrO_3 and $HOAc$ into benzophenone. Does not react with hydroxylamine or phenyl-hydrazine.

THIO-BENZOYL-(α)-NAPHTHYLAMINE v. vol. iii. p. 474.

THIOBENZPINAONE $C_{10}H_7S_2$ i.e.

$CPh_2(SH).CPh_2(SH)$ or $CPh_2.H.S.S.OPh_2H$. [151°]. Formed from benzophenone by the action of alcoholic ammonium sulphide (Engler, B. 11, 922) or P_2S_5 (Japp a. Roschen, C. J. 49, 479), and, together with thiobenzophenone, by the action of KSH on $C_6H_5.CCl_2.C_6H_5$ (Behr, B. 5, 970). Formed also by the action of alcoholic KSH on $(C_6H_5)_2CHCl$, and of P_2S_5 on di-phenyl-carbinol. Slender needles (from alcohol), v. sol. CS_2 . In alcoholic solution it is converted by finely-divided copper into tetra-phenyl-ethane $CHPh_2.CHPh_2$.

THIO-BIURET $C_{12}H_{11}N_2OS$. Formed by boiling carbimido-urea ('amidodicyan acid') with ammonium sulphide (Wunderlich, B. 19, 452). Needles (containing aq). Sol. hot water and alkalis, v. sl. sol. ether. Gives a white pp

with copper salts. By ammoniacal $AgNO_3$ it is converted back into carbimido-urea.

THIO-BUTYRIC ACID C_4H_7SO i.e.

$CH_3.CH_2.CH_2.CO.SH$. (180°). Formed by distilling butyric acid with P_2S_5 (Ulrich, A. 109, 280). Liquid with disgusting smell, v. sl. sol. water, v. sol. alcohol.— PbA_2 . Small crystals (from hot water).

Thio-isobutyric acid. *Methyl ether* C_4H_7SO i.e. $Pr.CO.SMe$. (c. 142°). V.D. 57.5. Formed from $Pb(SMe)_2$ and isobutyl chloride (Obermeyer, B. 20, 2922). Oil.

THIO-ISOBUTYRIC ALDEHYDE $Pr.OHS$. (70°-90°). A product of the action of S on isobutyric aldehyde at 180° (Barbaglia, G. 18, 85). Oil.

(α)-THIO-CARBAMIC ACID $NH_2.CO.SH$.

This acid, set free by adding acids to a solution of its ammonium salt, splits up at once into COS and ammonia. The ammonium salt $NH_4.CO.SNH_4$ is prepared by passing gaseous COS into alcoholic NH_3 (Berthelot, J. 1868, 160) or into NH_4Aq at 0° (Schmidt, B. 10, 191; Kretzschmar, J. pr. [2] 7, 474). It forms colourless crystals, v. e. sol. water, m. sol. alcohol, insol. ether. The dry salt becomes yellow in air, forming ammonium sulphocyanide. The dry salt forms thio-urea when heated in a sealed tube at 135°. Thio-urea is also formed when $Pb(OH)_2$ is added to its cold aqueous solution. HgO forms, in the cold, ammonium cyanate (Fleischer, B. 9, 438). Water at 100° forms NH_4SH and $(NH_4)HCO_3$. $FeCl_3$ gives a red liquid, and finally a red pp. (Mulder, A. 168, 228).

Methyl ether $NH_4.CO.SMe$. [c. 98°]. Formed, together with a small quantity of the (β)-isomeride, by adding HCl to a solution of potassium sulphocyanide in boiling $MeOH$ (Blankenhorn, J. pr. [2] 16, 375). Monoclinic prisms (from ether). Decomposed by alcoholic NH_3 into $MeSH$ and urea. Aniline at 100° forms $MeSH$, s-di-phenyl-urea and NH_3 .

Ethyl ether $NH_4.CO.SET$. [102°] (Pinner, B. 14, 1088); [108°] (F.). Formed in like manner (B.) and also by passing NH_3 into $Cl.CO.SET$ (Salomon, J. pr. [2] 7, 256) and by the action of $EtBr$ on $NH_4.CO.SNH_4$ (Fleischer, B. 9, 991). Plates, v. sol. hot water, alcohol, and ether. Decomposed at 150° into mercaptan and cyanuric acid. P_2O_5 converts it into ethyl sulphocyanide.

Isoamyl ether $CO(NH_4).SC_4H_{11}$. [107°]. From $CO(SC_4H_{11})Cl$ and NH_3 (Schöne, J. pr. [2] 32, 247). Glittering plates (from ether). Sol. hot water, but decomposed by boiling water. Gives amorphous pps., insol. water, alcohol, and ether with $AgNO_3$, $HgCl_2$ and $PtCl_4$.

Reactions.—Alcoholic NH_3 forms urea and amyl mercaptan.—2. Alcoholic KOH forms K_2CO_3 , NH_3 and amyl mercaptan.—3. Heated with aniline it forms NH_3 , HSC_4H_{11} , and di-phenyl-urea.

(β)-Thio-carbamic acid $NH_2.CS.OH$.

Methyl ether $NH_4.CS.OMe$. [43°]. Formed by the action of alcoholic NH_3 on $MeO.CS.SMe$ or on $MeO.CS.SET$ (Salomon, J. pr. [2] 8, 115).

Ethyl ether $NH_4.CS.OEt$. *Xanthogenamide*. [38°]. Formed by the action of NH_3 on xanthogenic ether $EtS.CS.OEt$, on $MeS.CS.OEt$, and on $(EtO.CS)_2S$ (Debus, A. 72, 1; 75, 121; 82, 258; Y Y

Chance, J. 1851, 513; Salomon a. Maintz, *J. pr.* [2] 8, 114). Monoclinic prisms, sl. sol. water, miscible with alcohol and ether. Decomposed on distillation into mercaptan and cyanic acid. Boiling KOHAq resolves it into alcohol and potassium sulphocyanide. P_2O_5 forms ethyl sulphocyanide (Conrad, *J. pr.* [2] 10, 84). Nitrous acid passed into water containing xanthogenamide in solution forms crystalline $C_2H_5N_2SO_2$. $CuSO_4$ followed by HClAq ppts. $C_2H_5NOSCuCl$ as a white crystalline powder, nearly insol. water, sol. hot alcohol. Compounds of $CuCl$ with 2, 3, and 4 mols. of xanthogenamide may be obtained. KI added to a boiling alcoholic solution of $(C_2H_5NOS)_2CuCl$ forms crystals of $(C_2H_5NOS)_2CuI$ and $(C_2H_5NOS)_2CuI$. Compounds $(C_2H_5NOS)_3CuSCy$ and $C_2H_5NOSCuSCy$ may also be prepared (Debus). Isovaleric aldehyde in presence of HCl and alcohol forms $C_4H_9CH(NH.CS.OEt)_2$ [108°] (Bischoff, *B.* 7, 1088). β -Iodo-propionic acid forms $NH_2.CO.S.CH_2.CH_2.CO_2H$ [147-5°], which yields CaA' , $3aq$, BaA' , $2aq$, and AgA' (Langlet, *B.* 24, 3849). β -Iodopropionic acid and Ac_2O yield sinapane propionic acid $CO<\frac{S-CH_2}{NH.CO}>CH_2$ [159°], v. sol. hot water, converted by HgO into the mercaptide of β -thiolactic acid.

Isobutyl ether $NH_2.CS.OCH_2Pr$. [36°]. Tables (from alcohol or ether) (Mylius, *B.* 5, 976; Blankenhorn, *J. pr.* [2] 16, 380).

Isoamyl ether $NH_2.CS.OCH_2H_{11}$. Oil (Johnson, *C. J.* 5, 242).

Di-thio-carbamic acid $NH_2.CS.SH$. Mol. w. 98. The ammonium salt $NH_4.CS.SNH_4$ is formed by passing NH_3 (from 150 pts. NH_4Cl) into 95 p.c. alcohol (600 pts.) containing CS_2 (96 pts.) (Mulder a. Bettink, *J. pr.* 103, 178; cf. Zeise, A. 48, 95; Debus, A. 73, 26). It is also formed by heating $(NH_4)_2CS_3$. On gradually adding HClAq to a cooled conc. solution of the ammonium salt the free acid separates as colourless needles, v. sol. water, alcohol, and ether; acid in reaction. An alcoholic solution of the acid gradually decomposes into CS_2 and the NH_4 salt. An aqueous solution of the acid decomposes on heating into H_2S and HCO_2S . The di-thio-carbamates also split at 100° into H_2S and sulphocyanides. An alcoholic solution of iodine decomposes $NH_4.CS.SNH_4$, forming $EtNCS$ and $EtNH_2$ (Hofmann, *Z.* [2] 5, 671). Ammonio di-thio-carbamate treated with HCl and solution of I gives crystals of the bisulphide $S_2(CS.NH_2)_2$ (Klason, *J. pr.* [2] 36, 62). $FeCl_3$ added to a solution of the NH_4 salt gives a black pp. turned white by excess. $AgNO_3$ gives a yellow pp., turning black. A solution of aldehyde forms carbothialdine $NH_2.CS.SN(C_2H_5)_2$. Benzoic aldehyde, isovaleric aldehyde, and acrolein form analogous bodies.

Salts.— NH_4A' . Deliquescent lemon-yellow prisms. On heating with KOHAq it forms K_2S , $KSCy$, and NH_3 .— CuA' . Yellow powder, insol. water.— PbA' . White pp., blackening on boiling with water.— ZnA' : white pp.

Ethyl ether $NH_2.CS.SET$. Mol. w. 121. [42°]. Formed by passing H_2S under pressure into ethyl sulphocyanide at 100° (Jeanjean, *J.* 1866, 501; Salomon a. Conrad, *J. pr.* [2] 10, 29). Trimetric crystals (from ether), insol. water, v. e. sol. alcohol. Alcoholic NH_3 or KOHAq in the

cold forms mercaptan and ammonium sulphocyanide.

Isopropyl ether $NH_2.CS.SPr$. [97°]. Trimetric plates (Gerlich, A. 178, 82).

Acetyl derivative of the ethyl ether $NHAc.CS.SET$. [128°]. Formed by heating thio-acetic acid with ethyl sulphocyanide (Chalaroff, *B.* 15, 1987). Yellow needles (from alcohol), v. sol. hot water. Decomposed by distillation into thio-acetic acid and ethyl sulphocyanide. Boiling baryta-water forms mercaptan and acetic acid. Hot dilute HClAq forms $NH_2.CS.SET$.

Isothiocarbamic ether v. Di-ethyl-(α)-thiocarbonate. Amide.

THIO-CARBAMIDE v. THIO-UREA.

THIOCARBAMYL SULPHIDE $C_2H_5N_2S$, i.e. $(NH_2.CS)_2S$ (?) Very unstable oil, got by adding HCl to its ammonium salt. Quickly decomposes into CS_2 , sulphur, H_2S , and ammonium sulphocyanide. The ammonium salt $C_2H_5(NH_2)_2N_2S_2$ is a product of the action of CS_2 on alcoholic NH_3 in the cold (Zeise, *B. J.* 4, 98; Hlasiwetz a. Kachler, A. 166, 187). It forms colourless prisms, v. sol. water, m. sol. alcohol, sl. sol. ether. The moist salt slowly decomposes into H_2S and ammonium sulphocyanide. The cupric salt $CuC_2H_5N_2S_2$ is canary-yellow.

Thiocarbamyl disulphide $C_2H_5N_2S_2$, i.e. $(NH_2.CS)_2S_2$. Formed by the action of Cl on a solution of the ammonium salt of the preceding body, and on ammonium di-thio-carbamate (Debus, A. 73, 27). Pearly plates, v. sol. hot alcohol, insol. water. Decomposed by boiling water into CS_2 , ammonium sulphocyanide, and S.

THIOCARBIMIDES. Mustard oils. Compounds $RN:CS$. Essential oil of mustard is allyl thiocarbimide. They are formed by the action of $CSCl_2$ on primary amines (Rathke, A. 167, 218), and by the action of aqueous $HgCl_2$ on the dithiocarbamates $RNH.CS.SNH_2R$ obtained by heating primary amines with CS_2 and alcohol or ether (Hofmann, *B.* 1, 171; 2, 452; 7, 811; 8, 106; Rudneff, *J. R.* 10, 188). Methyl sulphocyanide is partially converted into methyl thiocarbimide by heating at 180°. Allyl sulphocyanide changes to the mustard oil on boiling. Thiocarbimides are also got by distilling alkyl cyanates with P_2S_5 (Michael a. Palmer, *Am.* 6, 268). The thiocarbimides are pungent oils. They are reduced by Zn and HClAq to amines and CH_3S , whereas sulphocyanides yield HCy , mercaptans, and other products. Amines convert thiocarbimides into thio-ureas; thus aniline combines with phenyl thiocarbimide, forming *s*-di-phenyl-thio-urea. Alcoholic potash, or alcohol at 100° forms thio-carbamic ethers $NHR.CS.OEt$ (Hofmann, *B.* 2, 117; Schiiff, *B.* 9, 1316). Water at 200°, or HClAq at 100°, forms amine, CO_2 , and H_2S , while with sulphocyanides it yields Et_2S , CO_2 , and NH_3 . Conc. H_2SO_4 forms amine and COS . HNO_3 forms amine and CO_2 ; whereas with the isomeric sulphocyanides it forms a sulphonic acid. Hydroxylamine unites with thiocarbimides, forming oxy-thio-ureas $NHR.CO.NH.OH$ (Tiemann, *B.* 22, 1899). Chlorine unites with $PhN:CS$, forming unstable $(PhNCS)_2Cl_2$, whence boiling water

forms $(\text{PhNCS})_2\text{O}$ [118°], crystallising in yellow needles (Helmers, *B.* 20, 786).

THIOCARBIMIDO-ACETIC ACID $\text{C}_2\text{H}_3\text{NSO}_2$, i.e. $\text{CH}_2(\text{N}:\text{CS})\cdot\text{CO}_2\text{H}$. Formed by boiling thiohydantoin with HClAq (Volhard, *J. pr.* [2] 9, 6), and by boiling isoamyl sulphocynoacetate with fuming HClAq (Claesson, *B.* 10, 1852; Heintz, *A.* 136, 232). Trimetric plates, v. e. sol. hot water. Oxidised by HNO_3 to H_2SO_4 and oxalic acid. Weak acid.— BaA'_2 aq. Four-sided prisms, sl. sol. cold water. Benzoic aldehyde and NaOHAq (1 mol.) react, forming the compound $\text{CHPh}\cdot\text{C}(\text{CO}_2\text{Na})\cdot\text{S}\cdot\text{CO}\cdot\text{NH}_2$, which crystallises with $1\frac{1}{2}\text{aq}$ and is converted by HCl into CO_2S . $\text{NH}_2\text{CO} > \text{C}:\text{CHPh}$ [242°] (Andreasch, *M.* 10, 73).

THIOCARBIMIDO-BENZOIC ACID v. *m*-AMIDO-BENZOIC ACID.

THIOCARBONIC ACID.

Thiocarbonates v. vol. i. p. 703. The thiocarbonic ethers that have not been treated of in former articles are described below.

Methyl thiocarbonates v. vol. iii. p. 399.

Methyl iso-dithiocarbonate $\text{CO}(\text{SMe})_2$ (169°). Formed by warming methyl sulphocyanide with H_2SO_4 (Schmitt a. Glutz, *B.* 1, 166).

Ethyl thiocarbonates v. vol. ii. p. 520.

Ethylene thiocarbonates v. vol. ii. p. 493.

Ethylene di-ethyl di-thio-di-carbonate $\text{C}_2\text{H}_4(\text{S}\cdot\text{CO}\cdot\text{Et})_2$. Formed by heating $\text{C}_2\text{H}_5\text{Br}_2$ with $\text{KS}\cdot\text{CO}_2\text{Et}$ in alcohol (Welde, *J. pr.* [2] 15, 52). Thick oil, converted by alcoholic potash into $\text{C}_2\text{H}_4(\text{SH})_2$ and $\text{KO}\cdot\text{CO}_2\text{Et}$.

Isobutyl di-thio-carbonic acid $\text{CH}_3\text{Pr}\cdot\text{O}\cdot\text{CS}\cdot\text{H}$. Salts.— NaA' . Formed from $\text{C}_4\text{H}_9\text{ONa}$ and CS_2 . Yellowish white needles, v. e. sol. water and alcohol.— KA' . Needles (from alcohol). *S.G.* $\frac{15}{16}$ 1.371 (Clarke, *B.* 11, 1505). Chlorine gas passed into its aqueous solution forms oily $(\text{CH}_3\text{Pr}\cdot\text{O}\cdot\text{CS})_2\text{S}_2$ (Mylus, *B.* 5, 976).

Ethyl ether EtA' . (228°).

Isobutyl ether $\text{CH}_3\text{Pr}\cdot\text{O}\cdot\text{CS}\cdot\text{SCH}_2\text{Pr}$. (249°). *S.G.* $\frac{12}{13}$ 1.009 (Mylus, *B.* 5, 975).

Isoamyl ether $\text{CH}_3\text{Pr}\cdot\text{O}\cdot\text{CS}\cdot\text{SC}_2\text{H}_{11}$. (265°–270°) (Mylus).

Isoamyl di-thio-carbonic acid

$\text{C}_5\text{H}_{11}\cdot\text{O}\cdot\text{CS}\cdot\text{SH}$. Oil, with unpleasant smell.

Salts.— KA' . Formed from fusel oil, KOH , and CS_2 (Balard, *A. Ch.* [3] 12, 307; Erdmann, *J. pr.* 31, 4; Desains, *A. Ch.* [3] 20, 505; Johnson, *C. J.* 5, 142). Gives a lemon-yellow pp. with CuSO_4 .— PbA'_2 . Plates. Iodine forms oily $(\text{C}_5\text{H}_{11}\cdot\text{O}\cdot\text{CS})_2\text{S}_2$.

Di-isamyl s-di-thio-carbonate $\text{CO}(\text{SC}_5\text{H}_{11})_2$. (281°) (Schmitt a. Glutz).

Cetyl di-thiocarbonate v. vol. i. p. 728.

Iso-butyl-tri-thio-carbonic acid $\text{C}_4\text{H}_9\text{S}\cdot\text{CS}_2\cdot\text{H}$. Formed from $\text{C}_4\text{H}_9\text{SNa}$ and CS_2 (Mylus, *B.* 6, 316). The Na salt crystallises in yellow needles, v. sol. alcohol and ether.

Isobutyl ether $(\text{C}_4\text{H}_9\text{S})_2\text{CS}$. (287°). Got by heating aqueous K_2CS_3 with isobutyl iodide. Yellow oil with faint odour.

Di-isamyl-tri-thiocarbonate $(\text{C}_5\text{H}_{11}\text{S})_3\text{CS}$. (247°). *S.G.* .88 (Husemann, *A.* 126, 297). Oil, with unpleasant smell.

Di-allyl tri-thio-carbonate $(\text{C}_3\text{H}_5\text{S})_3\text{CS}$. (170°–175°). *S.G.* .94. Formed from allyl iodide and Na_2CS_3 in the cold (Husemann, *A.*

126, 269). Pungent yellow oil, with offensive odour.

THIOCARBONYL - ACETOACETIC ETHER $\text{CS}\cdot\text{OAc}\cdot\text{CO}_2\text{Et}$. [156°–162°]. Formed from thiocarbonyl chloride and acetoacetic ether (Bergreen, *B.* 21, 847). Yellow needles, sl. sol. ether and ligroin.

THIO - CARBONYL - DI-AMIDO-DI-BENZOIC ACID v. *m*-AMIDO-BENZOIC ACID.

THIOCARBONYL - BENZOYL - ACETIC ETHER $\text{CS}\cdot\text{CBz}\cdot\text{CO}_2\text{Et}$. [164°]. Formed from CSCl_2 and benzoylacetate ether (Bergreen, *B.* 21, 351). Yellow needles, sol. alcohol-chloroform.

THIO-CARBONYL CHLORIDE v. *Sulphochloride of CARBON*.

Thio-carbonyl tetrachloride v. *PER-CHLORO-METHYL-MERCAPTAN*.

THIO - CARBONYL - ETHYL - o - AMIDO-PHENOL $\text{C}_6\text{H}_4\langle\text{NMe}\rangle\text{CS}$. [112°]. (above

300°). Formed from ethyl-o-amido-phenol and CSCl_2 (Seidel, *J. pr.* [2] 42, 449, 457). Insol. water and dilute NaOHAq , m. sol. cold alcohol. HClAq at 170° forms ethyl-amido-phenol, CO_2 , and H_2S . PCl_5 yields $\text{C}_6\text{H}_4\langle\text{N}\rangle\text{CSCl}$.

THIO - CARBONYL - METHYL - AMIDO-PHENOL $\text{C}_6\text{H}_4\langle\text{NMe}\rangle\text{CS}$. [128°]. (above

300°). Formed by the action of CSCl_2 on methyl-o-amido-phenol (Seidel, *J. pr.* [2] 42, 452). Needles, insol. water, sl. sol. cold alcohol.

THIO - CARBONYL - DI - (β) - NAPHTHYL - THIO - UREA $\text{C}_{10}\text{H}_7\text{N}\langle\text{CS}\rangle\text{C}(\text{NO}_2\text{H}_2)\text{S}$. [152°].

Formed from di-(β)-naphthyl-thio-urea and CSCl_2 in benzene (Freund a. Wolf, *B.* 25, 1466). Stellate groups of needles, m. sol. hot benzene. Melts at 152° with evolution of gas, forming a solid melting at 224°.

THIO-CARBONYL-DI-p-TOLYL-THIO-UREA $\text{C}_7\text{H}_7\text{N}\cdot\text{C}\langle\text{N}(\text{C}_6\text{H}_5)\rangle\text{CS}$. [109°]. Formed from

di-p-tolyl-thio-urea [172°] and CSCl_2 in ether (Freund a. Wolf, *B.* 25, 1465). Yellowish needles, v. sol. hot alcohol and ether. Converted by HgO into carbonyl-di-tolyl-thio-urea [112°].

THIOCHRONIC ACID $\text{C}_6\text{H}_4\text{S}_2\text{O}_4$, i.e. $\text{C}_6(\text{OH})(\text{SO}_2\text{H})(\text{SO}_2\text{H})_2$. Formed by adding tetrachloro-quinone to a conc. solution of K_2SO_3 (Hesse, *A.* 114, 313; Graebe, *A.* 146, 40). Yellow trimetric prisms, v. sol. hot water, insol. alcohol. Coloured brownish-red by FeCl_3 . Reduces AgNO_3 . Converted into hydroquinone disulphonic acid by heating with water at 135°, or by boiling with HClAq .

Euthiochronic acid $\text{C}_6\text{H}_4\text{S}_2\text{O}_4$, i.e. $\text{C}_6(\text{OH})_2\text{O}_2(\text{SO}_2\text{H})_2$. *Di-oxy-quinone disulphonic acid*. Formed by boiling thiochronic acid with KOH . Deliquescent yellow needles, v. sol. water and alcohol. Reduced by tin and HClAq to $\text{C}_6\text{H}_4\text{S}_2\text{O}_4$, which yields $\text{Na}_2\text{A}'_2$ 2aq and $\text{K}_2\text{A}''$ 2aq, which are re-oxidised in aqueous solution by air to euthiochronates.— $\text{Na}_2\text{A}'$ aq (dried at 150°).— $\text{K}_2\text{A}'$ 2aq. Minute lemon-yellow prisms, v. sol. water.— $\text{K}_2\text{HA}'$ aq. Small orange-red four-sided prisms.— $\text{Ba}_2\text{A}'$ 4aq. Ochre-yellow pp.— $\text{Ag}_2\text{A}'$: amorphous pp.

(a) **THIO - CINNAMIC ACID** $\text{C}_6\text{H}_5\text{SO}$ i.e. $\text{C}_6\text{H}_5\text{CH}:\text{CH}\cdot\text{CO}\cdot\text{SH}$. Formed from cinnamoyl chloride and $\text{Pb}(\text{SEt})_2$, the resulting oily ether

being boiled with alcoholic KSH (Engelhardt, Z. [2] 4, 359).—KA'. Crystalline.

(β)-Thio-cinnamic acid. *Amide* $C_6H_5S.NH_2$. [112°]. Formed by passing H_2S into a solution of cinnamic nitrile in alcoholic NH_3 (Rossum, Z. 1866, 862; Krüss, B. 17, 1768). Golden plates.

(α)-THIO-CINNAMIC ALDEHYDE (C_6H_5S). [167°]. Formed by passing H_2S into oil of cinnamon dissolved in alcoholic HCl (Baumann & Fromm, B. 24, 1452). Crystalline, v. e. sol. benzene, sl. sol. alcohol.

(β)-Thio-cinnamic aldehyde (C_6H_5S). [213°]. Formed at the same time as the (α)-isomeric. Prisms, v. sl. sol. cold benzene and alcohol.

Thio - cinnamic orthoaldehyde. *Phenyl ether* $C_6H_5CH:CH.CH(SPh)_2$. [81°]. Formed by passing dry HCl into a mixture of cinnamic aldehyde and phenyl mercaptan (Baumann, B. 18, 885). Needles (from ligroin).

p-Bromo-phenyl ether $CHPh.CH.OH(S.C_6H_4Br)_2$. [107°]. Needles (from alcohol or ether).

Glycolyl ether $CHPh.CH.OH(S.CH_2.CO_2H)_2$. [143°]. Formed from cinnamic aldehyde and thioglycollic acid (Bongartz, B. 21, 481). Plates (from water). Zinc-dust in alkaline solution converts it into $CHPh.CH.CH_2S.CH_2.CO_2H$ [77°], crystallising from dilute alcohol in plates.

TRI-THIO-ITRITIC ETHER $C_6H_5O(CO.SET)_3$. Formed from tri-phenyl citrate and NaSEt in presence of ether (Seiffert, J. pr. [2] 31, 470). Oil, smelling like mercaptan.

THIO-COUMARIN $C_6H_4 \begin{array}{c} \diagup CH:CH \\ \diagdown O \quad | \\ \quad CS \end{array}$. [101°].

Formed by heating equal parts of coumarin and P_2S_5 at 120°; the yield is 50 p.c. Also by heating o-coumaric acid with P_2S_5 . Long yellow needles, v. sol. alcohol, ether, and benzene; insol. water. Sublimable. By heating with aqueous alcoholic KOH it is reconverted into coumarin. Unlike coumarin it readily reacts with hydroxylamine and with phenyl-hydrazine (Tiemann, B. 19, 1661).

THIO-CRESOL v. TOLYL MERCAPTAN.

THIO-CROCONIC ACID $C_6H_2O_3S$, probably $SO \begin{array}{c} \diagup C(OH).CO \\ \diagdown C(OH).CO \end{array}$. Formed by saturating a warm solution of potassium croconate treated with 2 mols. of HCl, with H_2S .—BaA'' 2aq: brownish-yellow amorphous pp., v. sol. dilute HCl, which after some time changes to reddish-brown crystals with violet reflex, insol. dilute HCl (Nietzki & A. Benkiser, B. 19, 299).

THIO-CUMINIC ACID. *Amide* C_6H_5NS i.e. $C_6H_5.C_6H_4.CS.NH_2$. Formed by passing H_2S into a solution of cuminic nitrile in alcoholic NH_3 (Czumpelik, B. 2, 185). Needles, v. sol. hot alcohol. Converted in alcoholic solution by iodine into $C_{20}H_{22}N_2S$ [45°] crystallising in prisms (Wanstrat, B. 6, 322).

THIODICYANDIAMIDINE v. GUANYL THIO-UREA.

THIOCYANIC ACID v. SULPHOCYANIC ACID.

THIOCYANO- v. SULPHOCYANO-.

DI-THIO-CYANURIC ACID $Cy_2(SH)_2(OH)aq$.

Preparation.—An alcoholic solution of KCyS is mixed with the calculated quantity of HCl, filtered from KCl, and evaporated at 40°. The residue is extracted with strong NH_4Aq and

$BaCl_2$ is added to the filtrate. The barium salt gradually separates in globular crystals (Klason, J. pr. [2] 33, 121). Yield, very small.

Properties.—White scales (from hot water). Sol. NaOHAq. A solution of the potassium salt gives pps. with $AgNO_3$, $HgCl_2$, and $Pb(OAc)_2$.

Reactions.—1. Conc. HCl at 180° gives cyanuric acid and H_2S .—2. Cold $KMnO_4Aq$ and hot HNO_3Aq form cyanuric acid.—3. Iodine forms $(HOCCy)_2S$ as a white crystalline powder.

Salts.— KH_2A''' . Silvery mass of microscopic prisms.— $BaHA'''2aq$.

Tri-thio-cyanuric acid $Cy_3(SH)_3$. Formed by warming powdered $C_3N_3Cl_3$ (1 mol.) with conc. aqueous KSH (4 mols.) (Hofmann, B. 18, 2196; Klason, J. pr. [2] 33, 116). Minute prisms, when ppd. from dilute solutions; amorphous, from conc. solutions. Nearly insol. hot water, alcohol and ether. Not decomposed at 200°. $FeCl_3$ gives no colour in solutions of the acid, but in conc. solutions of the K salt it gives a white pp. and a yellow solution.

Reactions.—1. $HClAq$ at 130° gives cyanuric acid and H_2S .—2. Alkaline $KMnO_4$ at 20° gives cyanuric acid.—3. Warm HNO_3 forms cyanuric acid.—4. At 360° it gives off CS_2 and some $HCyS$ and leaves melem $C_6H_3N_3$.

Salts.— $K_3A'''3aq$.— $K_3H_2A'''6aq$.— NaH_2A''' . Crystals, v. sol. water.— $BaHA'''3aq$. Yellow crystals, ppd. by addition of $BaCl_2$ and NH_4Aq .— $BaH_2A'''2aq$. Prisms, m. sol. water.— $SrHA'''5aq$.— $CaHA'''5aq$. Prisms, m. sol. water.

Methyl ether Me_3A''' . [189°]. Got by heating methyl sulphocyanide with a few drops of $HClAq$ at 100° (Hofmann, B. 13, 1351; 18, 2197, 2755, 2774; 19, 2065). Hexagonal crystals. An alcoholic solution of ethylamine at 100° forms $Cy_2(NHET)(SMe)_2$ [114°] while at 140° it yields $Cy_2(NHET)SMe$ [84°]. Alcoholic NH_3 forms, in like manner, $Cy_2(NH_2)(SMe)_2$ and $Cy_2(NH_2)SMe$.

Ethyl ether Et_2A''' . [27°]. (350°). Formed from Cy_2Cl_2 and NaSEt. Colourless tablets (from HOAc) converted by alcoholic NH_3 at 180° into $Cy_2(NH_2)(SEt)_2$ [112°] (crystallising in trimetric forms; $a:b:c = .669:1:391$, v. sol. ether), accompanied by $Cy_2(NH_2)_2(SEt)_2$ [165°], which is insol. ether (Klason, J. pr. [2] 33, 298).

Amyl ether $(C_5H_{11})_2A'''$. Oil. Yields $Cy_2(NH_2)(SC_5H_{11})_2$ [82°] and $Cy_2(NH_2)_2SC_5H_{11}$ [178°].

Phenyl ether Ph_2A''' . [97°]. Prisms (from HOAc).

p-Tolyl ether $(C_6H_4)_2A'''$. [114°].

THIO-DI-ETHYL-ANILINE v. TETRA-ETHYL-DI-AMIDO-DI-PHENYL SULPHIDE.

THIO-ETHYL-COUMARIN $C_6H_4 \begin{array}{c} \diagup CH:CEt \\ \diagdown O \quad -CS- \end{array}$. [94°]. Formed by heating (α)-ethyl-coumarin with P_2S_5 at 120° (Aldringen, B. 24, 3462). Yellowish-red plates, sol. alcohol. May be sublimed.

THIO-ETHYLENE GLYCOL v. ETHYLENE MERCAPTAN.

THIO-FORMIC ACID $H.CO.SH$ (?) [120°]. Formed by the action of H_2S on lead formate (Wöhler, A. 91, 125; Limpricht, A. 97, 361), but not from P_2S_5 and formic acid (Hurst, A. 126, 68). Small transparent crystals (from alcohol) with alliaceous odour, insol. water. May be sublimed. According to Nicol (Pr. E. 10, 425) a solution of thioformic acid, got from

PbA', and H_2S , rapidly decomposes, yielding formic acid.

Salts.— $H.CO.SK$. Formed from $CHCl_3$ and alcoholic K_2S (Nicol, *T. E.* 29, 531). Needles, sol. water and alcohol, nearly insol. dilute alcohol. $AgNO_3$ added to its aqueous solution forms a white pp., turning black on standing. HNO_3 yields S and formic acid. HgO also gives formic acid.—($H.CO.S$), Pb.

Anilide $H.CS.NHPh$. *Thioformanilide*. [137°]. Formed from dry phenyl carbamine and H_2S (Hofmann, *B.* 10, 1095, 1238). Formed also by passing dry H_2S over di-phenyl-formamidine $NPh.CH.NHPh$ at 150° (Bernthsen, *A.* 192, 35). Prepared by warming formamidine (5 pts.) with P_2S_5 (3 pts.), the yield being 60 p.c. of the theoretical (Hofmann, *B.* 11, 338). Thin plates (from water), partially decomposed on distillation into H_2S and phenyl carbamine. Its solution tastes bitter. Decomposed by hot KOH aq into aniline, H_2S , and formic acid. Heated in a sealed tube at 180° it yields $C_6H_5N_2S$ [140°] v. sol. alcohol (Nicol, *B.* 15, 211). $NaOEt$ and $EtBr$ yield oily $CH(SET):NPh$ (c. 235°) (Wallach a. Wüsten, *B.* 16, 145).

***o*-Toluide** $H.CS.NHC.H$, [96°]. Got by heating formyl-toluide with P_2S_5 (Senier, *C. J.* 47, 762).

***p*-Toluide**. Yellow needles.

Xylido $HCS.NHC.H_2Me$, [105°]. Small needles (from alcohol) (Gudeman, *B.* 21, 2549).

Thio-orthoformic acid. *Ethyl ether* $CH(SET)_2$. Formed by boiling chloroform with aqueous $NaSEt$ (Gabriel, *B.* 10, 186; Claesson, *J. pr.* [2] 15, 174). Oil, with nasty smell, partly decomposed on boiling. Oxidised by HNO_3 to ethane sulphonic acid. Fuming HCl aq yields formic acid and mercaptan.

Benzyl ether $CH(SC_6H_5)_2$, [98°]. Formed from $NaSC_6H_5$ and chloroform (Dennstedt, *B.* 11, 2265). White crystals.

Phenyl ether $CH(SPh)_3$, [39.5°]. Trimetric tables. Oxidised by potassium permanganate to $PhS.CH(SO_2Ph)_2$ [176°] (Laves, *B.* 23, 1416; 25, 347).

Reference.—CHLOROFORMIC ACID.

THIO-FORMIC ALDEHYDES

Thio-formic paraldehyde $(CH_2S)_3$. *Methyl-ene sulphide*. Mol. w. 138. [216°]. V.D. 5.08 (obs.).

Formation.—1. By heating Na_2S with methylene iodide (Husemann, *A.* 126, 293).—2. By reducing CS_2 with Zn and HCl aq (Girard, *A.* 100, 306).—3. By the action of H_2S on formic aldehyde or trioxymethylene.

Preparation.—By saturating a mixture of formic aldehyde (2 vols.) and conc. HCl aq (4 vols.) with H_2S (Baumann, *B.* 23, 67).

Properties.—Prisms, smelling like onions. Insol. cold water, sl. sol. alcohol and ether, m. sol. benzene and CS_2 . May be sublimed. Oxidised by $KMnO_4$ to a trisulphone and also $C_6H_5S_2O_3$, crystallising in colourless needles.—Forms: $C_3H_4S_3.2AgNO_3$.— $C_3H_4S_3.AgNO_3.3aq$.— $C_3H_4S_3.HgCl_2$.— $(C_3H_4S_3)_2PtCl_2$.— $(C_3H_4S_3)_2PtCl_4$ (Hofmann, *B.* 2, 162; 3, 584; Girard, *C. R.* 70, 625).

Thio-formic orthaldehyde.

Ethyl ether $CH_3(SET)_2$, (184°) (C); (180°) (F). S.G. 22.967. Formed from CH_3I and $NaSEt$ (Claesson, *J. pr.* [2] 15, 176). Liquid

with unpleasant smell. Oxidised by HNO_3 to ethane sulphonic acid. $KMnO_4$ and H_2SO_4 yield $CH_3(SO_3C_2H_5)_2$ (Fromm, *A.* 253, 155).

Thio-formic metaldehyde $(CH_2S)_n$, [176°]. Formed, as a white amorphous substance, on warming an aqueous or alcoholic solution of hexamethylene-amine saturated with H_2S (Wohl, *B.* 19, 2344). Insol. most solvents. Decomposed when heated above its melting-point.

Di-thio-formic paraldehyde $(C_2H_4S_2O)_n$, aq. *Dithioglyceric aldehyde*. [82°]. (180°–185°). Formed by passing H_2S into a solution obtained by electrolysis of dilute glycerin (Renard, *A. Ch.* [5] 17, 307). Amorphous waxy mass, sol. warm water, insol. alcohol and ether.

(a) **THIO-FURFURALDEHYDE** $(C_5H_4SO)_n$, [128°]. Formed, together with the (*β*)-isomeride, by passing H_2S into a solution of furfuraldehyde (10 g.) in alcohol (100 c.c.) and HCl aq (20 c.c.) at -5° (Baumann a. Fromm, *B.* 24, 8598). Crystals, v. e. sol. alcohol and chloroform, insol. water.

(β) **Thio-furfuraldehyde** $(C_5H_4SO)_n$, [229°]. Needles, v. sl. sol. alcohol, v. sol. chloroform.

Thio-furfuraldehyde $(C_5H_4SO)_n$ [$n = 20$ to 24]. Mol. w. (by Raoult's method) 2182. Formed by mixing an alcoholic solution of furfuraldehyde with alcoholic ammonium sulphide (Cahours, *A.* 69, 85; B. a. F.). White crystalline powder, softens at 80° and is melted at 91°. Thiofurfuraldehyde is decomposed by warm aniline, yielding furfuraldehyde and H_2S (Schiff, *B.* 19, 2153).

THIO-GLYCERIN v. GLYCERIN.

THIO-GLYCOL v. ETHYLENE MERCAPTAN.

THIO-GLYCOLLIC ACID $CH_2(SH).CO_2H$. *Sulphydro-acetic acid*.

Formation.—1. By reducing the compound $ClSO_2.CHCl.COCl$ with tin and HCl aq (Siemens, *B.* 6, 669).—2. By adding $CH_2Cl.CO_2H$ (1 mol.) to conc. $KSHAq$ (2 mols.) (Claesson, *A.* 187, 113).—3. By the action of H_2S on glyoxylic acid in presence of Ag_2O (Böttiger, *A.* 198, 215).—4. By boiling thiohydantoin with baryta-water (Andreasch, *B.* 12, 1385).—5. Together with $HSCy$, by the decomposition of rhodanic acid $C_2H_4NS_2O$ with baryta-water (Ginsberg a. Bondzynski, *B.* 19, 113).

Properties.—Oil, miscible with water, alcohol, and ether. Decomposes when quickly heated. Very dilute $FeCl_3$ gives a fugitive indigo-blue colour, changed by a few drops of NH_4Aq to dark red and then to violet. Excess of $FeCl_3$ oxidises it to di-sulphido-di-acetic acid $S_2(C_2H_4.CO_2H)_2$, which is also readily formed by atmospheric oxidation of the alkaline solution. A solution of the K salt added to $CuSO_4$ gives a bluish-black pp. reduced by further addition of the K salt to the white cuprous salt $Cu_2(S.CH_2.CO_2H)_2$. HCl passed through a mixture of thioglycollic acid and acetoacetic ether gives rise to crystalline $CO_2Et.CH_2.CMe(S.CH_2.CO_2H)_2$ [96°] (Bongartz, *B.* 21, 485). Acetyl-propionic acid forms, in like manner, $CO_2H.CH_2.CH_2.CMe(S.CH_2.CO_2H)_2$ [154°]. Aldehydes react, forming the compound $CRH(S.CH_2.CO_2H)_2$, compounds which are produced either on standing, on warming, or on treatment with $ZnCl_2$ or dry HCl (Bongartz, *B.* 19, 1981; 21, 479). Such compounds obtained by using acetic, benzoic, cinnamic, *o*-oxy-benzoic, and *o*-, *m*-, and *p*-nitro-benzoic aldehydes melt at 108°, 124°, 148°, 148°, 128°, 180°, and 162° respec-

tively. Thioglycollic acid reacts with ketones in presence of ZnCl_2 or HCl , forming acids $\text{CRB}(\text{S}(\text{CH}_2\text{CO}_2\text{H})_2)$; such compounds obtained from acetone, acetophenone, and benzophenone melt at 135° , 139° , and 164° respectively.

Salts.— KHA'' aq (from water).— KHA'' (from alcohol). Decomposes K_2CO_3 , forming $\text{CH}_3(\text{SK})\text{CO}_2\text{K}$.— BaA'' 3aq: crystalline pp.— BaA'' : gummy.— CdA'' .— $\text{Hg}(\text{S}(\text{CH}_2\text{CO}_2\text{H})_2)$. Needles or flat prisms, v. sol. hot water and alcohol.— $\text{Hg}_2(\text{S}(\text{CH}_2\text{CO}_2)_2)_2\text{BaH}_2$. Minute crystals.— $\text{Hg}_2(\text{S}(\text{CH}_2\text{CO}_2)_2)_2\text{AlH}_3$.— $\text{Hg}_2\text{MnH}_2\text{A}''$.— HgPbA'' .— HgA'' .— PbA'' .— $\text{Bi}(\text{HA}'')$. [c. 33°]. Yellow pp.— $\text{Cu}_2\text{H}_2\text{A}''$. White pp.— $\text{Cu}_2\text{BaA}''$.— AgA'' .— $\text{Ag}_2(\text{NH}_4)\text{A}''(\text{NO}_3)$.— $\text{Ag}_2\text{HgA}''$.

Ethyl ether EtA. Formed by boiling thioglycollic acid with alcohol and a little H_2SO_4 (Claesson, A. 187, 116). Oil with nasty smell. Slowly decomposed by boiling into H_2S and $\text{S}(\text{CH}_2\text{CO}_2\text{Et})_2$. Alcoholic HgCl_2 ppts. $\text{ClHg}(\text{S}(\text{CH}_2\text{CO}_2\text{Et})_2)$, converted by excess of the ether into $\text{Hg}(\text{S}(\text{CH}_2\text{CO}_2\text{Et})_2)$ (Wislicenus, A. 146, 145).

Ethyl derivative $\text{CH}_3(\text{SEt})\text{CO}_2\text{H}$. Formed by mixing $\text{CH}_3\text{Cl}.\text{CO}_2\text{Et}$ with NaSEt and alcohol (Claesson, B. 8, 120). Liquid, v. sol. alcohol and ether, m. sol. water. Decomposed by heat, but may be distilled with steam.— KA' .— BaA' .— CaA' .— MgA' .3aq.— ZnA' .2aq.— CdA' .aq. [85°].— CoA' .2aq. [90°].— NiA' .2aq.— CuA' .2aq.— AgA' aq. Crystalline pp.

Ethyl ether of the ethyl derivative $\text{CH}_3(\text{SEt})\text{CO}_2\text{Et}$. (188°). S.G. ± 1.0469 . Oil. Converted by EtI at 120° into crystalline $\text{CH}_3(\text{SEtI})\text{CO}_2\text{Et}$.

Ethyl ether of the isoamyl derivative $\text{CH}_3(\text{SO}_2\text{H}_1)\text{CO}_2\text{Et}$. (230°). S.G. $\pm .9797$. Oil.

Phenyl derivative v. PHENYL-THIO-GLYCOLLIC ACID.

Benzyl derivative $\text{CH}_3\text{Ph}.\text{S}(\text{CH}_2\text{CO}_2\text{H})_2$. [59°]. Formed from $\text{CH}_3\text{Cl}.\text{CO}_2\text{H}$ and benzyl mercaptan (Gabriel, B. 12, 1641). Flat tables. Yields EtA' (275° – 290°) and the amide $\text{CH}_3\text{Ph}.\text{S}(\text{CH}_2\text{CONH}_2)_2$ [97°] crystallising in flat plates.

Phenyl-phenyl derivative $\text{C}_6\text{H}_5\text{Ph}.\text{S}(\text{CH}_2\text{CO}_2\text{H})_2$. [170°]. Crystals.

Amide $\text{CH}_3(\text{SH})\text{CO}.\text{NH}_2$. A product of the passage of H_2S through an alcoholic solution of chloro-acetamide containing a little NH_3 (Schulze, Z. 1865, 73). Groups of small prisms.

Ethyl derivative of the amide $\text{CH}_3(\text{SEt})\text{CONH}_2$. [44°]. Formed from $\text{CH}_3(\text{SEt})\text{CO}_2\text{Et}$ and ammonia. Thin prisms.

Reference.—NITROSO-THIO-GLYCOLLIC ACID.

THIO-GLYCOLLIC ORTHALDEHYDE. *Ethyl derivative of the ether* $\text{CH}_3(\text{SEt})\text{CH}(\text{OEt})_2$. (169°). Formed from $\text{CH}_3\text{Cl}.\text{CH}(\text{OEt})_2$ and NaSEt (Autenrieth, B. 24, 162). Volatile in steam.

Phenyl derivative of the ethyl ether $\text{CH}_3(\text{SPh})\text{CH}(\text{OEt})_2$. (278°). Got in like manner.

THIO-HYDANTOIC ACID $\text{C}_2\text{H}_4\text{N}_2\text{SO}_2$, i.e. $\text{NH}_2.\text{CS}.\text{NH}.\text{CH}_2\text{CO}_2\text{H}$ or $\text{NH}_2.\text{C}(\text{NH})\text{S}(\text{CH}_2\text{CO}_2\text{H})_2$. Formed by heating sodium chloro-acetate in aqueous solution with thio-urea (Maly, A. 189, 880). Crystalline powder, al. sol. water, v. sol. acids and alkalis. Decomposed by heat. Converted into thio-

hydantoin by warming with Na_2CO_3 aq or HCl aq.

THIOHYDANTOIN $\text{C}_2\text{H}_4\text{N}_2\text{SO}$ i.e.

Formation.—1. By heating thio-urea with chloro-acetic acid or chloro-acetamide (Volhard, A. 166, 383; Mulder, B. 8, 1264; Maly, A. 168, 133; B. 10, 1853; Claesson, B. 10, 1852).—2. By heating thioglycollic acid (2 mols.) with cyanamide (1 mol.) in aqueous solution (Andreasch, B. 13, 1421; M. 1, 442).

Preparation.—Thio-urea (50 g.) dissolved in water (500 c.c.) is mixed with chloro-acetic acid (62 g.) in water (50 c.c.), heated to 90° , cooled, and mixed with the calculated quantity of NaOH (Andreasch, M. 8, 414).

Properties.—Long needles (from hot water), insol. alcohol and ether. Decomposes about 200° . Since it cannot be desulphurised by HgO , Liebermann (A. 207, 132) suggests that it does not contain the group CS .

Reactions.—1. Chlorine passed into its cooled solution in HCl aq forms thio-oxy-hydantoin (Kramps, B. 13, 788).—2. Br forms di-bromothio-hydantoin.—3. KClO_3 and HCl yield $\text{C}_2\text{H}_4\text{KN}.\text{SO}_3$, crystallising in monoclinic tables, S. 1.7 at 22° ; 23.3 at 100° , converted by nitrous acid into $\text{SO}_2\text{H}.\text{CH}_2\text{CO}_2\text{H}$, and by baryta-water into sulpho-acetic acid and urea (Andreasch, B. 13, 1423; M. 4, 131).—4. Baryta-water forms thioglycollic acid and dicyandiamide.—5. Boiling HCl aq forms thiocarbimido-acetic acid.

Salts.— $\text{Ag}_2\text{C}_2\text{H}_4\text{N}_2\text{SO}_2$.— $\text{B}'_2\text{H}_2\text{SO}_4$. Plates.— $\text{B}'\text{HNO}_3$.— $\text{B}'\text{HCl}$.— $\text{B}'\text{H}_2\text{C}_2\text{O}_4$ aq. Prisms.— $\text{B}'_2\text{H}_2\text{PtCl}_6$.— $\text{B}'\text{C}_2\text{H}_4\text{N}_2\text{O}$. Minute yellow needles.

References.—DI-BROMO- and NITROSO-THIO-HYDANTOIN.

DI-THIO-HYDROQUINONE $\text{C}_6\text{H}_4(\text{SH})_2$ [98°].

Formed by reducing benzene *p*-disulphonic chloride with tin and HCl aq (Körner a. Monsele, G. 6, 142). Formed also from $(\text{C}_6\text{H}_4(\text{NH}_2))_2\text{S}_2$ by diazotisation, treatment with potassium xanthate, and saponification of the product with alcoholic potash (Leuckart, J. pr. [2] 41, 205). Six-sided plates, slowly oxidised by air.

THIO-ISATYDE v. ISATYDE.

THIO-LACTIC ACID $\text{CH}_3.\text{CH}(\text{SH})\text{CO}_2\text{H}$. *α -Sulphydro-propionic acid.*

Formation.—1. From α -chloro-propionic acid and KHS (Schacht, A. 129, 1; Lovén, J. pr. [2] 29, 368).—2. By the action of H_2S on silver α -chloro-propionate or silver pyruvate (Böttiger, A. 188, 320; B. 9, 404, 804, 1061; 11, 1561; 18, 486).

Preparation.—By saturating a solution of pyruvic acid with H_2S , and adding conc. HCl aq and zinc (Lovén).

Properties.—Syrup, miscible with water, alcohol, and ether. May be distilled *in vacuo*. Its odour is unpleasant. FeCl_3 gives a transient indigo colour, and then oxidises it to sulphido-dipropionic acid. CuSO_4 gives a violet solution; a smaller quantity of CuSO_4 ppts. the cuprous salt. Cobalt acetate and air gives a brown colour.

Salts.— BaA' , (at 180°). Gummy mass.— $\text{Hg}(\text{S}.\text{CHMe}.\text{CO}_2\text{H})_2$.— $\text{Hg}(\text{S}.\text{CHMe}.\text{CO}_2\text{K})_2$ aq. $\text{Hg}(\text{S}.\text{CHMe}.\text{CO}_2)_2$.— Ba_2 aq. — $\text{AgS}.\text{CHMe}.\text{CO}_2\text{H}$.

—Bi(S.CHMe.CO₂H)₂. — Pt(S.CHMe.CO₂H)₂. — CuS.CHMe.CO₂H. Yellow pp.—PbC₂H₃O₂S.
Ethyl ether EtA'. Oil. Yields

CuS.CHMe.CO₂Et as a yellowish powder.

THIO-DILACTYLIC ACID v. SULPHIDO-DI-PROPIONIC ACID.

THIO-MALIC ACID C₄H₄SO₄. Formed from bromo-succinic acid and aqueous KSH at 110° (Carius, A. 129, 6). Deliquescent mass, oxidised by dilute HNO₃ to sulpho-succinic acid.—BaA". —Ag₂A". Bulky pp., readily blackening.

THIO-MESITOL v. TRI-METHYL-PHENYL MERCAPTAN.

THIO-DI-METHYL-ANILINE v. TETRA-METHYL-DI-AMIDO-DI-PHENYL SULPHIDE.

THIO-METHYL-COUMARILIC ETHER

C₁₂H₁₂SO₂ i.e. C₆H₅<CMe>C.CO.SET. [91°].

Formed from methyl-coumarilic ether and P₂S₅ (Hantzsch, B. 19, 2400). Yellow needles (from alcohol), v. sol. ether.

THIO-(α)-METHYL-COUMARIN C₁₀H₈SO i.e.

C₆H₅<CH₂CMe>O-CS. [122°]. Formed by heating

(α)-methyl-coumarin with P₂S₅ at 120° (Aldringen, B. 24, 3460). Yellow needles, insol. water, v. sol. alcohol. Converted by alcoholic potash into (α)-methyl-coumarin.

THIO-METHYL-DI-PHENYL-AMINE v. METHYL-IMIDO-DI-PHENYL SULPHIDE.

THIO-METHYL-URACIL C₄H₄N₂SO i.e.

CS<NH.CMe>CH(?). S. 054 at 21°. Formed by the action of alcoholic potash on the needles which separate after some days from a solution of thio-urea (1 mol.) and acetoacetic ether (1 mol.) in alcohol to which a little HCl has been added (Nencki a. Sieber, J. pr. [2] 25, 72; List, A. 236, 1; Behrend, B. 19, 219). Plates, v. sl. sol. ether. Decomposed at 280°.

Reactions.—1. The K salt reacts with EtI forming C₄H₄N₂SOEt [145°], and with MeI forming C₄H₄N₂SOMe [220°], which yields C₄H₄AgN₂SO. —2. *Chloro-acetic ether* forms C₄H₄N₂SO(CH₂.CO.Et) [143°], which yields C₄H₄N₂SO(CH₂.CO.H) [204°]. —3. Br forms methyl-uracil, and finally di-oxy-methyl-uracil. Cl acts in like manner, forming C₄H₄Cl₂N₂O₂. —4. On warming with lead hydrate in strongly alkaline solution it is converted into methyl-uracil. Conc. HClAq at 150°, conc. NH₄Aq at 150°, and Ac₂O at 185° also form methyl-uracil.

Salts. — C₄H₄Ag₂N₂SO. — C₄H₄CuN₂SO. — (C₄H₄N₂SO)₂Hg. — C₄H₄N₂NaSO 2aq. — C₄H₄N₂KSO ½aq.

THIONAMIC ACID. H. Rose (P. 33, 235; 42, 415) found that SO₂ and NH₃ combined in equal volumes, when dry NH₃ was mixed with excess of dry SO₂, to form a yellowish white solid, which quickly decomposed in solution, or moist air, giving (NH₄)₂SO₄ and ammonium salts of other sulphur oxyacids. Rose concluded that the substance was SO₂.NH₃, from the fact that it was formed by combining equal volumes of the two gases; if this empirical formula is accepted the compound may be SO₂.NH₃.H or SO.OH.NH₃. When dry SO₂ was mixed with excess of dry NH₃, Rose found that 1 vol. SO₂ combined with 2 vols. NH₃; the product—an amorphous, white solid—may be SO₂.NH₃.NH₃ or SO.OH.NH₃.

M. M. P. M.

THIONAMIDE. By passing NH₃ into cooled S₂Cl₂ Schiff (A. 102, 111) obtained a white solid which was decomposed by warm water to (NH₄)₂SO₄Aq. The solid contained NH₄Cl; Schiff regarded it as a mixture of this salt with SO(NH₂)₂; he did not attempt to separate the supposed thionamide from NH₄Cl.

M. M. P. M.

(α)-**THIO-NAPHTHOIC ACID.**

Amide C₁₀H₇.CS.NH₂. [126°]. Formed from (α)-naphthoic nitrile and alcoholic ammonium sulphide at 80°-35° (Hofmann, B. 1, 40; Bamberger, B. 21, 54). Crystals, v. sol. alcohol.

Tetrahydride of the amide

CH₂.CH₂>C₆H₄.CS.NH₂. Formed by digesting a solution of tetrahydride of (α)-naphthoic nitrile in alcoholic ammonia saturated with H₂S for some days at 30°-40° (Bamberger a. Bordt, B. 22, 629). Dark-yellow oil.

(β)-**Thio-naphthoic acid.** *Amide*

C₁₀H₇.CSNH₂. [149°]. Formed from (β)-naphthoic nitrile and ammonium sulphide at 35°-40° (Bamberger a. Bockmann, B. 20, 1115). Needles, v. sol. alcohol. Dissolves in hot water, being slowly converted into the nitrile.

THIO-NAPHTHOL v. NAPHTHYL MERCAPTAN.

THIO-DI-NAPHTHYL-AMINE v. IMIDO-DI-NAPHTHYL SULPHIDE.

THIONATES. Salts of the *thionic acids* (q. v., p. 698). Four series of thionates are known; a fifth probably exists: M₂S₂O₆=dithionates; M₂S₃O₆=trithionates; M₂S₄O₆=tetra-thionates; M₂S₅O₆=pentathionates; and probably M₂S₆O₆=hexathionates. The thionates are formed by the action of alkalis on the liquid obtained by passing H₂S into saturated SO₂Aq; also by the oxidation of sulphites, thiosulphates, and mixtures of these, and in other reactions (cf. THIONIC ACIDS, p. 698). For general qualitative reactions of thionates and thiosulphates v. Debus (C. J. 53, 298).

DITHIONATES, M₂S₂O₆, M^{III}S₂O₆, and M^{III}(S₂O₆)₂. (*Hyposulphates*.) The alkali salts are formed by the interaction of a dilute solution of I in KIAq and dilute NaHSO₄Aq (Spring a. Bourgeois, Bl. [2] 46, 151; Sokoloff a. Mattscheffski, B. 14, 2058); also by the reaction of KMnO₄ on thiosulphates in acetic acid solution, or on sulphites or trithionates (Hönig a. Zatzek, M. 4, 738; Fordos a. Gélis, J. Ph. [3] 36, 113). The Ba salt is formed by passing SO₂ into water holding MnO₂ in suspension, filtering, and adding BaOAq (for more details v. DITHIONIC ACID, p. 698); most of the other dithionates are obtained by the interaction of BaS₂O₆Aq and sulphates; several have been prepared by digesting H₂S₂O₄Aq with metallic hydroxides. The dithionates are sol. water; the salts of the alkali and alkaline earth metals are not readily decomposed either in solution or as solids; solutions of most of the other salts are decomposed, by heat, giving off SO₂ (v. Klüss, A. 246, 179, 284; Geuther, A. 226, 232).

Dithionates give off SO₂ when heated to redness, leaving normal sulphates; thus M₂S₂O₆=SO₂+M₂SO₄; this reaction is characteristic; so also is the reaction of H₂SO₄Aq or HClAq with boiling solutions of dithionates, whereby H₂SO₄Aq is formed and SO₂ is given off, without separation of S.

Ammonium dithionate $(\text{NH}_4)_2\text{S}_2\text{O}_8$. Obtained by decomposing the Ba salt in solution by $(\text{NH}_4)_2\text{SO}_4$ aq, filtering and crystallising. S.G. 1.704 (Topsoë, C. C. 4, 76). Klüss (A. 246, 179, 284) gives formula $2\text{Am}_2\text{S}_2\text{O}_8 \cdot \text{aq}$, and says the salt crystallises in monoclinic needles. Very sol. water; insol. alcohol. Aqueous solution may be boiled without change. Forms *double salts* with AmCl (Fock a. Klüss, B. 24, 3017); also with the dithionates of Al, Cd, Co, Cu, Fe, Mn, Ni, and Zn (K., l.c.).

Barium dithionate $\text{BaS}_2\text{O}_8 \cdot 2\text{aq}$. Formed by passing SO_2 into water at c. 0° holding coarsely-powdered MnO_2 in suspension, till the MnO_2 is dissolved ($\text{MnO}_2 + \text{SO}_2 + \text{Aq} = \text{MnSO}_4\text{Aq}$; and also $\text{MnO}_2 + 2\text{SO}_2 + \text{Aq} = \text{MnS}_2\text{O}_8\text{Aq}$), filtering if necessary, adding BaOAc to alkaline reaction ($\text{MnS}_2\text{O}_8\text{Aq} + \text{BaO} \cdot \text{H}_2\text{Aq} = \text{BaS}_2\text{O}_8\text{Aq} + \text{MnO} \cdot \text{H}_2$), filtering from $\text{MnO} \cdot \text{H}_2$, evaporating, and recrystallising from water (cf. Stas, *Chem. Propert.* 117). White prisms; S. 24.75 at 18° , 90.9 at 100° , 100.6 at 102° = b.p. of saturated solution; insol. alcohol. The crystals effloresce in air, losing $2\text{H}_2\text{O}$; a hydrate with $4\text{H}_2\text{O}$ is obtained by slow evaporation (v. Heeren, P. 7, 55; Gay-Lussac, A. Ch. [2] 10, 812; Baker, C. N. 36, 203; cf. Spring a. Bourgeois, Bl. [2] 46, 151. For crystalline form v. Senarmont, J. 1857, 142; Rammelsberg, P. 58, 295; von Lang, W. A. B. 45 [2] 27). Schiff (A. 105, 239) described *double salts* with MgS_2O_8 and $\text{Na}_2\text{S}_2\text{O}_8$ (cf. Kraut, A. 118, 95); Bodländer (*Chem. Zeit.* 14, 1140) described a double salt with $\text{Rb}_2\text{S}_2\text{O}_8$; and Klüss (A. 246, 179, 284) double salts with $\text{Ag}_2\text{S}_2\text{O}_8$ and $\text{Tl}_2\text{S}_2\text{O}_8$.

Many of the other dithionates are prepared from the Ba salt.

Potassium dithionate $\text{K}_2\text{S}_2\text{O}_8$. Prepared from a solution of the Ba salt by adding an equivalent quantity of K_2SO_4 in solution, warming, filtering, and evaporating; also by boiling $\text{K}_2\text{S}_2\text{O}_8\text{Aq}$ with MnO_2 , filtering, and separating from K_2SO_4 by fractional crystallisation (K_2SO_4 is much less sol. water than $\text{K}_2\text{S}_2\text{O}_8$). White, hexagonal crystals; unchanged in air; decrepitate when heated and then gives off SO_2 and leaves K_2SO_4 ; S.G. 2.277 (Topsoë, Bl. [2] 19, 246). The crystals rotate the plane of polarisation of light; an aqueous solution is optically inactive (Pape, P. 139, 224). S. c. 6 at ordinary temperature, c. 66 at 100° ; insol. alcohol (Heeren, P. 7, 55).

Sodium dithionate $\text{Na}_2\text{S}_2\text{O}_8 \cdot 2\text{aq}$. Prepared similarly to the K salt. Also formed, according to Bunte (B. 7, 646), by heating $\text{Na} \cdot \text{Et} \cdot \text{S}_2\text{O}_8$ for some time at 100° (Et, S_2 distills off). Large, lustrous, rhombic prisms; unchanged in air; S.G. 2.175 at 11° (Baker, C. N. 36, 203). S. 47.6 at 16° ; 90.9 at 100° ; insol. alcohol. Solution is slowly reduced by sodium-amalgam to $\text{Na}_2\text{SO}_4\text{Aq}$ (Spring, B. 7, 1161). Kraut (A. 117, 97) described a hydrate with $6\text{H}_2\text{O}$.

Dithionates of the following metals have also been described (the figures indicate the references): Al (1) (8); Be (8); Bi (8); Cd (1) (2) (4); Ca (1) (4) (5); Cr (8); Co (1) (2) (3) (4); Cu (8); Fe (1) (3) (4); Pb (1) (4) (5); Li (2) (4); Mg (1) (4) (5); Mn (4); Hg (1) (2) (8); Ni (2) (4) (5); Rb (8); Ag (1) (2) (4) (5); Sr (2) (4); Tl (8); Sn (8); U (8); Zn (1) (2) (4).

(1) Heeren, P. 7, 72, 171; (2) Rammelsberg,

P. 58, 298; (3) Klüss, A. 246, 179, 284; (4) Topsoë, C. C. 4, 76; (5) Baker, C. N. 36, 203; (6) Piccard, J. pr. 86, 456.

TRITHIONATES $\text{M}^+\text{S}_3\text{O}_6$ and $\text{M}^{++}\text{S}_3\text{O}_6$. The alkali salts are formed by digesting conc. MHSO_4Aq with S at 50° – 60° ($6\text{MHSO}_4\text{Aq} + 2\text{S} = 2\text{M}_2\text{S}_3\text{O}_6\text{Aq} + \text{M}_2\text{S}_2\text{O}_8\text{Aq} + 8\text{H}_2\text{O}$) (Pelouze, A. Ch. [3] 79, 85); also by heating dilute MHSO_4Aq , or keeping the solution for a long time in a closed tube (Saint-Pierre, C. R. 62, 632); by passing SO_2 into $\text{M}_2\text{S}_2\text{O}_8\text{Aq}$ ($2\text{M}_2\text{S}_2\text{O}_8\text{Aq} + 3\text{SO}_2 = 2\text{M}_2\text{S}_3\text{O}_6\text{Aq} + \text{S}$); by passing SO_2 into M_2SAq (Chancel a. Diacon, J. pr. 90, 35; Rathke, J. pr. 95, 11); by the interaction of I and a mixture of M_2SO_4 and $\text{M}_2\text{S}_2\text{O}_8$ in solution ($\text{M}_2\text{SO}_4\text{Aq} + \text{M}_2\text{S}_2\text{O}_8\text{Aq} + \text{I}_2 = \text{M}_2\text{S}_3\text{O}_6\text{Aq} + 2\text{MIAq}$) (Spring, B. 7, 1157); by the interaction of boiling water on AgKSO_3 or $\text{HgNa}_2(\text{S}_2\text{O}_3)_2$, whereby $\text{K}_2\text{S}_3\text{O}_6\text{Aq}$ or $\text{Na}_2\text{S}_3\text{O}_6\text{Aq}$ is formed, along with Ag_2S or HgS (Spring, l.c.); by reacting on $\text{M}_2\text{SO}_4\text{Aq}$ with $\text{S} \cdot \text{Cl}$ (Spring, B. 6, 1108); by decomposing $\text{M}_2\text{S}_2\text{O}_8\text{Aq}$ by a non-oxidising acid, e.g. by H_2SO_4 (Spring a. Levy, *Bull. de l'Acad. roy. de Belge*, 42, 108); by heating $(\text{NH}_4)_2\text{SO}_3$ with $\text{P} \cdot \text{S}$, Spring (B. 7, 1158) obtained a little $(\text{NH}_4)_2\text{S}_3\text{O}_6$, along with much $(\text{NH}_4)_2\text{S}_2\text{O}_8$, some NH_3 , polysulphides, and P compounds; $\text{K}_2\text{S}_3\text{O}_6$ is also obtained from Wackenroder's solution.

The trithionates are soluble in water; they very readily decompose; heated with water they give off SO_2 , deposit S, and form sulphates in solution. Addition of excess of CuSO_4Aq to solution of a trithionate causes ppn. of CuS and evolution of SO_2 (Spring, B. 6, 1108).

SELENOTRITHIONATES $\text{M}_2\text{SeS}_3\text{O}_6$ are described as *dithio-triselenates* under SELENATES (p. 434).

Potassium trithionate $\text{K}_2\text{S}_3\text{O}_6$. A conc. solution of $\text{K}_2\text{S}_2\text{O}_8$ is formed by dissolving the salt in 8 pts. water and 1 pt. alcohol till the alcohol separates from the aqueous solution; SO_2 is passed into this solution at 25° – 30° , solid $\text{K}_2\text{S}_3\text{O}_6$ being added from time to time, till the liquid is yellow and smells of SO_2 ; the crystals that separate are dissolved in water at 60° – 70° , the solution is filtered from S, mixed with eight times its volume of 84 p.c. alcohol, warmed gently, and allowed to crystallise (Plessy, A. Ch. [3] 20, 162; for other methods of preparation v. Langlois, A. Ch. [2] 79, 77; Rathke, J. 1864, 164; Chancel a. Diacon, C. R. 56, 710). White rhombic needles (Baker, C. N. 36, 203). Very sol. water, insol. alcohol. Aqueous solution gives $\text{K}_2\text{SO}_4\text{Aq}$, SO_2 , and S when heated. Debus (C. J. 53, 818) found that $\text{K}_2\text{S}_3\text{O}_6\text{Aq}$ slowly changes at the ordinary temperature, giving $\text{K}_2\text{SO}_4\text{Aq}$, $\text{K}_2\text{S}_2\text{O}_8\text{Aq}$, and $\text{K}_2\text{S}_2\text{O}_8\text{Aq}$ without separation of S. According to C. a. D. (l.c.), $\text{K}_2\text{S}_3\text{O}_6\text{Aq}$ interacts with $\text{K}_2\text{S}_2\text{O}_8\text{Aq}$ to give only $\text{K}_2\text{S}_3\text{O}_6\text{Aq}$; with H_2S the products are $\text{K}_2\text{SO}_4\text{Aq}$, $\text{K}_2\text{S}_2\text{O}_8\text{Aq}$, and S (Debus, C. J. 53, 829). Sodium-amalgam reacts readily, producing KNaS_2O_6 and KNaSO_4 (Spring, B. 7, 1161).

The other trithionates that have been isolated are those of Ba (Kessler, P. 74, 253); Pb (K., l.c.); Chancel a. Diacon, C. R. 56, 710); Na (K., l.c.); Rathke, J. pr. 95, 18; Villiers, C. R. 106, 1856); and Zn (Fordos a. Gélis, A. Ch. [8] 22, 66).

TETRATHIONATES $\text{M}^+\text{S}_4\text{O}_6$ and $\text{M}^{++}\text{S}_4\text{O}_6$. The alkali salts are formed by triturating $\text{M}_2\text{S}_2\text{O}_8$ with I, adding a little water and pouring into

alcohol (von Klobukoff, *B.* 18, 1869; Ellasberg, *B.* 19, 822; Fock a. Klüss, *B.* 23, 2429); the Pb salt is formed by the prolonged interaction of I and PbS_2O_6 , also by the interaction of $\text{H}_2\text{SO}_4\text{Aq}$ and a mixture of PbS_2O_6 with PbO_2 (Chancel a. Diacon, *J. pr.* 90, 55); tetrathionates are also formed, according to Spring a. Levy (*Bull. de l'Acad. roy. de Belge*, 42, 108), by the interaction of thiosulphates and ferrous or cuprous salts, KMnO_4Aq , hypochlorites, or KClO_4 dissolved in $\text{H}_2\text{SO}_4\text{Aq}$. $\text{K}_2\text{S}_2\text{O}_8$ is obtained by neutralising Wackenroder's solution by $\text{KO}_2\text{H}_2\text{O}_2$ (v. Debus, *C. J.* 53, 278; cf. Curtius a. Henkel, *J. pr.* [2] 37, 187). The tetrathionates are e. sol. water, but insol. alcohol; aqueous solutions are generally decomposed on evaporation.

Potassium tetrathionate $\text{K}_2\text{S}_4\text{O}_{10}$. Formed by adding I, little by little, to conc. $\text{K}_2\text{S}_2\text{O}_8\text{Aq}$ till a permanent reddish-brown colour is produced, dissolving the crystals that separate in warm water, filtering from S, adding alcohol till the pp. that forms is re-dissolved, and allowing to crystallise (Kessler, *P.* 74, 258). Spontaneous decomposition of conc. $\text{K}_2\text{S}_2\text{O}_8\text{Aq}$ gives $\text{K}_2\text{S}_2\text{O}_8$ and S (Debus, *C. J.* 53, 311). Perfectly dry $\text{K}_2\text{S}_2\text{O}_8$ can be kept unchanged in a dry atmosphere; but in ordinary air, after a time, SO_2 is formed; an aqueous solution of $\text{K}_2\text{S}_2\text{O}_8$ slowly changes to $\text{K}_2\text{S}_2\text{O}_8\text{Aq}$, $\text{K}_2\text{S}_2\text{O}_8\text{Aq}$, $\text{K}_2\text{SO}_4\text{Aq}$, and SO_2 (D., l.c.). BrAq reacts to form $\text{H}_2\text{SO}_4\text{Aq}$, S, and KBr ; but if the BrAq is added very gradually the S that is formed combines with residual $\text{K}_2\text{S}_2\text{O}_8$ to form $\text{K}_2\text{S}_2\text{O}_8$; similarly, if a little K_2SO_4 is added to $\text{K}_2\text{S}_2\text{O}_8\text{Aq}$ and H_2S is then passed in, K_2SO_4 and S are formed, and the S combines with unchanged $\text{K}_2\text{S}_2\text{O}_8$ to form $\text{K}_2\text{S}_2\text{O}_8$ (D., l.c. p. 315). Sodium-amalgam forms $\text{KNaS}_2\text{O}_8\text{Aq}$ (Spring, *B.* 7, 1161).

The other tetrathionates that have been isolated are those of Ba (Lewes, *C. J.* 39, 69; Fordos a. Gélis, *A. Ch.* [3] 22, 66; Curtius a. Henkel, *J. pr.* [2] 37, 187); Od (Kessler, *P.* 74, 253); Cu (Chancel a. Diacon, *C. R.* 56, 510); Fe (F. a. G.); Pb (K.; C. a. D.); Na (K.; von Klobukoff, *B.* 18, 1869); Sr (K.); and Zn (F. a. G.).

PENTATHIONATES $\text{M}_2\text{S}_5\text{O}_{12}$ and $\text{M}^+\text{HS}_5\text{O}_{11}$. Wackenroder, in 1845 (*A.* 60, 189), asserted that the liquid formed by passing H_2S into SO_2Aq contained pentathionic acid $\text{H}_2\text{S}_5\text{O}_{11}$; other chemists confirmed his results, and prepared a few salts of the acid (v. Lenoir, *A.* 62, 253; Fordos a. Gélis, *A. Ch.* [3] 22, 66; Kessler, *P.* 74, 257; Ludwig, *Ar. Ph.* [2] 85, 9; Chancel a. Diacon, *C. R.* 56, 710). At a later time the existence of pentathionates was denied, chiefly by Spring (*B.* 12, 2254; 13, 924; 15, 2618), but upheld by Kessler (*B.* 13, 424; v. also Takamatsu a. Smith, *B.* 13, 1976). In 1881 Lewes (*C. J.* 39, 68) seemed to have isolated $\text{BaS}_5\text{O}_{12}$ and $\text{K}_2\text{S}_5\text{O}_{12}$, but Spring failed to confirm his results. Shaw, however, (*C. J.* 48, 357), repeated Lewes's experiments, and obtained $\text{K}_2\text{S}_5\text{O}_{12}$. In 1888 Debus (*C. J.* 53, 278) made an elaborate investigation of Wackenroder's solution, and prepared $\text{K}_2\text{S}_5\text{O}_{12}$ therefrom. Curtius a. Henkel (*J. pr.* [2] 37, 187) assert that Wackenroder's solution contains acid tetrathionates, in which the ratio of S to Ba is greater than 4S:Ba, and that these have been mistaken for pentathionates. But Debus's experiments seem to have settled

the dispute in favour of the existence of pentathionates. Ammoniacal AgNO_3Aq gives very distinct brown colouration, followed by a black pp. with pentathionates; this reaction distinguishes them from salts of other S oxyacids (v. Debus, l.c., p. 297).

Potassium pentathionate $2\text{K}_2\text{S}_5\text{O}_{12}$. 8aq. Debus (*C. J.* 53, 294) prepared this salt from Wackenroder's solution (v. p. 698) by adding 16.66 g. $\text{KO}_2\text{H}_2\text{O}_2$ (previously fused) to 48 c.c. of the solution of S.G. 1.848; the $\text{KO}_2\text{H}_2\text{O}_2$ was dissolved in as little water as possible acidulated with a few drops of acetic acid; the solution was placed in a large flat dish in a current of air until the liquid had evaporated; the crystalline residue (weighing 26 g.) was repeatedly pressed between filter-paper, and then dissolved in 60 c.c. water + 1 c.c. H_2SO_4 , at 40°; the minute quantity of S that separated (c. .005 g.) was filtered off, and the filtrate was allowed to crystallise in a flat dish. The crystals that separated (18.75 g.) were a mixture of $\text{K}_2\text{S}_5\text{O}_{12}$ and $\text{K}_2\text{S}_4\text{O}_{10}$; they were dried by placing them on blotting paper, and the crystals of pentathionate were picked out (5.75 g. were obtained), crystallised twice from water acidulated with a little $\text{H}_2\text{SO}_4\text{Aq}$, and dried over H_2SO_4 . The crystals of pentathionate form four-sided rhombic plates, or six-sided star-like plates; those of tetrathionate form six-sided prisms, with pyramids only on one end, and with the side on which they rest much developed. Lewes (*C. J.* 39, 75) described three salts: $\text{K}_2\text{S}_5\text{O}_{12}$, $\text{K}_2\text{S}_5\text{O}_{12} \cdot \text{H}_2\text{O}$, and $\text{K}_2\text{S}_5\text{O}_{12} \cdot 2\text{H}_2\text{O}$; Debus's salt was $2\text{K}_2\text{S}_5\text{O}_{12} \cdot 3\text{H}_2\text{O}$. According to Fock a. Klüss (*B.* 23, 2428), this is the only salt that exists (cf. D., l.c., p. 297). The salt can also be obtained by passing H_2S into $\text{K}_2\text{S}_2\text{O}_8\text{Aq}$ acidulated with $\text{H}_2\text{SO}_4\text{Aq}$ (D., l.c., p. 315).

Crystals of $2\text{K}_2\text{S}_5\text{O}_{12} \cdot 3\text{H}_2\text{O}$ begin to decompose, when kept in a stoppered bottle, after a month or so, giving eventually a yellow, pulpy mass of $\text{K}_2\text{S}_2\text{O}_8$, S, and water; the decomposition is caused by water in the interstices of the crystals. By powdering finely, washing with dilute alcohol, and placing over H_2SO_4 , Debus (l.c. p. 295) kept the salt unchanged for two or three years. $2\text{K}_2\text{S}_5\text{O}_{12} \cdot 3\text{H}_2\text{O}$ dissolves in c. 2 parts water, forming a clear, neutral solution, which soon decomposes with separation of S and formation of $\text{K}_2\text{S}_2\text{O}_8\text{Aq}$ (D., l.c., p. 311); addition of a drop of dilute KOH to the solution causes separation of S (p. 291); H_2S ppt. much S, and $\text{K}_2\text{S}_2\text{O}_8$ and K_2CO_3 are formed in the solution (p. 328); SO_2 produces $\text{K}_2\text{S}_2\text{O}_8\text{Aq}$ and $\text{K}_2\text{S}_2\text{O}_8\text{Aq}$ (p. 332); the salt is insoluble in alcohol.

Barium pentathionate $\text{BaS}_5\text{O}_{12}$. 8aq; obtained by Lewes (*C. J.* 39, 68) by partially neutralising Wackenroder's solution by BaOAq , crystallising over H_2SO_4 , pouring off from $\text{BaS}_5\text{O}_{12}$, and again crystallising.

Copper pentathionate $\text{CuS}_5\text{O}_{12}$. 4aq; obtained by Debus (l.c., p. 300) in blue, prismatic crystals, by adding $\text{Cu}(\text{C}_2\text{H}_3\text{O}_2)_2\text{Aq}$ to Wackenroder's solution and allowing to evaporate. Debus probably obtained *zinc pentathionate*, but not in a pure state (l.c., p. 299).

HEXATHIONATES. By adding $\text{KO}_2\text{H}_2\text{O}_2\text{Aq}$ to the mother-liquor from $\text{K}_2\text{S}_5\text{O}_{12}$ and $\text{K}_2\text{S}_4\text{O}_{10}$ (v. *supra*), evaporating in a current of air, dis-

solving in water with a little $\text{H}_2\text{SO}_4\text{Aq}$, allowing to evaporate in portions, and collecting the crystals separately, Debus (*C. J.* 53, 301) obtained a salt in which the ratio of S to O was almost 6S:6O, as required by *potassium hexathionate*.

THIONESSAL v. TETRA-PHENYL-THIOPHENE.

THIONIC ACIDS. The acids $\text{H}_2\text{S}_x\text{O}_6\text{Aq}$, where $x=2, 3, 4, 5$, and probably 6, are generally called thionic acids, and are distinguished as *di-, tri-, &c.*, thionic acid. The acids are known only in aqueous solutions; most of these solutions readily oxidise to $\text{H}_2\text{SO}_4\text{Aq}$. Dithionic acid is produced by the action of certain oxidisers on $\text{H}_2\text{SO}_3\text{Aq}$; dithionates are formed by oxidising sulphites and thiosulphates; trithionates are formed when mixtures of sulphites and thiosulphates are oxidised, also when SO_2Aq interacts with alkali thiosulphates; tetrathionates result by the action of certain oxidisers on thiosulphates. These processes may be represented diagrammatically as follows (the actual reactions are much more complex):

- (1) $2\text{H}_2\text{SO}_3\text{Aq} + \text{O} = \text{H}_2\text{S}_2\text{O}_6\text{Aq} + \text{H}_2\text{O}$;
- (2) $2\text{M}_2\text{SO}_3\text{Aq} + \text{O} = \text{M}_2\text{S}_2\text{O}_6\text{Aq} + \text{M}_2\text{O}$;
 $\text{M}_2\text{S}_2\text{O}_6\text{Aq} + 3\text{O} = \text{M}_2\text{S}_3\text{O}_6\text{Aq}$;
- (3) $\text{M}_2\text{SO}_3\text{Aq} + \text{M}_2\text{S}_2\text{O}_6\text{Aq} + \text{O} = \text{M}_2\text{S}_3\text{O}_6\text{Aq} + \text{M}_2\text{O}$;
 $2\text{M}_2\text{S}_2\text{O}_6\text{Aq} + 3\text{SO}_2\text{Aq} = 2\text{M}_2\text{S}_3\text{O}_6\text{Aq} + \text{S}$;
- (4) $2\text{M}_2\text{S}_2\text{O}_6\text{Aq} + \text{O} = \text{M}_2\text{S}_3\text{O}_6\text{Aq} + \text{M}_2\text{O}$.

After passing H_2S for a long time into nearly saturated $\text{H}_2\text{SO}_3\text{Aq}$, the solution contains $\text{H}_2\text{S}_2\text{O}_6$, much $\text{H}_2\text{S}_3\text{O}_6$, $\text{H}_2\text{S}_4\text{O}_6$, and probably $\text{H}_2\text{S}_5\text{O}_6$, along with H_2SO_3 , dissolved colloidal S, and a little S in suspension. This solution is known as *Wackenroder's solution* (Wackenroder, *A.* 60, 189 [1845]). It has been examined by many chemists; a very thorough investigation was made by Debus in 1888 (*C. J.* 53, 278; where references will be found to other memoirs). The solution examined by Debus was prepared by passing a slow current of H_2S into 480 c.c. nearly saturated SO_2Aq at a little above 0° for two hours, keeping in a stoppered bottle for forty-eight hours at the ordinary temperature, passing in H_2S for two hours, after forty-eight hours again passing in H_2S , and repeating these treatments until the liquid no longer smelled of SO_2 , after standing for a couple of hours at the ordinary temperature (about two weeks were required before the action was completed). The liquid thus obtained contains a large quantity of S, partly as a hard brittle solid, partly as a soft and gummy mass, and partly in suspension in minute particles which pass through filter paper; the liquid remains milky after filtration, and does not become clear on standing for two or three weeks (regarding the variety of S in solution, v. SULPHUR, *Allotropic forms of*, p. 608). Debus (*L.c.*, p. 348) thinks that the product of the direct interaction of SO_2Aq and H_2SAq is $\text{H}_2\text{S}_2\text{O}_6$ ($8\text{SO}_2\text{Aq} + \text{H}_2\text{SAq} = \text{H}_2\text{S}_2\text{O}_6\text{Aq}$); that part of this $\text{H}_2\text{S}_2\text{O}_6$ reacts with excess of SO_2Aq to form $\text{H}_2\text{S}_3\text{O}_6\text{Aq}$ and $\text{H}_2\text{S}_4\text{O}_6\text{Aq}$ ($?\text{H}_2\text{S}_2\text{O}_6\text{Aq} + \text{H}_2\text{SO}_3\text{Aq} = \text{H}_2\text{S}_3\text{O}_6\text{Aq} + \text{H}_2\text{S}_2\text{O}_6\text{Aq}$), and that part of the $\text{H}_2\text{S}_2\text{O}_6\text{Aq}$ reacting with $\text{H}_2\text{S}_2\text{O}_6\text{Aq}$ forms $\text{H}_2\text{S}_3\text{O}_6\text{Aq}$ ($?\text{H}_2\text{S}_2\text{O}_6\text{Aq} + \text{H}_2\text{S}_2\text{O}_6\text{Aq} = \text{H}_2\text{S}_3\text{O}_6\text{Aq} + \text{H}_2\text{SO}_3\text{Aq}$) (*D., l.c.*, p. 333); that the H_2S reacts with $\text{H}_2\text{S}_2\text{O}_6\text{Aq}$ to form H_2O and S, part of the S combining, as it is formed, with $\text{H}_2\text{S}_2\text{O}_6\text{Aq}$ to form $\text{H}_2\text{S}_3\text{O}_6\text{Aq}$, $\text{H}_2\text{S}_4\text{O}_6\text{Aq}$ and $\text{H}_2\text{S}_5\text{O}_6\text{Aq}$, and part

remaining in solution as colloidal S. If H_2S is passed into Wackenroder's solution, more $\text{H}_2\text{S}_2\text{O}_6$ is formed; and if the passage of H_2S is continued until all reaction ceases the thionic acids are decomposed, and the final products are S and H_2O , so that the equation $\text{SO}_2\text{Aq} + 2\text{H}_2\text{SAq} = 3\text{S} + 2\text{H}_2\text{Oaq}$ correctly represents the interaction of SO_2Aq with H_2SAq so far as the final products are concerned (*v. D., l.c.*, p. 351).

Solutions of the thionic acids more or less rapidly decompose, the final products being $\text{H}_2\text{SO}_4\text{Aq}$, SO_2Aq , and S; oxidisers such as Cl or HNO_3Aq —in some cases air is sufficient—convert them into $\text{H}_2\text{SO}_4\text{Aq}$; reducers, such as Na amalgam, produce $\text{H}_2\text{S}_2\text{O}_6\text{Aq}$, sometimes also $\text{H}_2\text{SO}_3\text{Aq}$, and in some cases H_2SAq . None of the acids has been isolated apart from water; salts of all are known (*v. THIONATES*, p. 695). The acids are all dibasic.

Regarding the constitution of the thionic acids v. Mendeléeff, *B.* 3, 870; Michaelis, *A.* 170, 31; Spring, *B.* 6, 1108; Debus, *C. J.* 53, 351.

DITHIONIC ACID $\text{H}_2\text{S}_2\text{O}_6\text{Aq}$. (*Hyposulphuric acid.*) A solution of this acid is formed by suspending coarsely-powdered MnO_2 in water, and passing in SO_2 while the liquid is kept at $c. 0^\circ$; filtering, adding BaOaq to alkaline reaction, and filtering from BaSO_4 and MnO_2H_2 ; evaporating, crystallising out BaS_2O_6 , 2aq, and decomposing this salt in solution by the equivalent quantity of $\text{H}_2\text{SO}_4\text{Aq}$; filtering from BaSO_4 , and evaporating *in vacuo* till a liquid of S.G. 1.347 is obtained ($\text{MnO}_2 + 2\text{SO}_2\text{Aq} = \text{MnS}_2\text{O}_6\text{Aq}$; $\text{MnO}_2 + \text{SO}_2\text{Aq} = \text{MnSO}_3\text{Aq}$) (Spring a. Bourgeois, *B.* [2] 46, 151). If evaporation is continued beyond this concentration, $\text{H}_2\text{SO}_3\text{Aq}$ and SO_2 are formed; the same decomposition occurs when $\text{H}_2\text{S}_2\text{O}_6\text{Aq}$ is evaporated by heat. $\text{H}_2\text{S}_2\text{O}_6\text{Aq}$ is reduced by Zn and HClAq to $\text{H}_2\text{SO}_3\text{Aq}$ at 0° (Otto, *A.* 147, 187); it is oxidised to $\text{H}_2\text{SO}_4\text{Aq}$ by Cl, HNO_3 , KClO_3 , and HCl &c.; it slowly oxidises in air (*cf. DITHIONATES*, p. 695). Thomson (*Th.* 2, 259) gives the following heats of formation of $\text{H}_2\text{S}_2\text{O}_6\text{Aq}$:— $[\text{S}^{2+}\text{O}_6\text{Aq}] = 211,080$; $[2\text{SO}^{2+}\text{O}_6\text{Aq}] = 68,920$; $[2\text{SO}^{2+}\text{O}_6\text{Aq}] = 53,520$; for the heat of oxidation of $\text{H}_2\text{S}_2\text{O}_6\text{Aq}$ to $\text{H}_2\text{SO}_4\text{Aq}$ he gives $(\text{S}_2\text{O}_6\text{Aq} + \text{O} = 2\text{SO}_3\text{Aq})$ $[\text{S}^{2+}\text{O}_6\text{Aq}] = 73,740$.

TRITHIONIC ACID $\text{H}_2\text{S}_3\text{O}_6\text{Aq}$. A dilute solution of this acid is formed by decomposing $\text{K}_2\text{S}_3\text{O}_6\text{Aq}$ by the equivalent quantity of HClO_4Aq or $\text{H}_2\text{SiF}_6\text{Aq}$, and filtering from KClO_4 , or K_2SiF_6 (Langlois, *C. R.* 10, 461; 62, 842; Kessler, *P.* 74, 250). The dilute solution cannot be evaporated, even *in vacuo*, without partial decomposition, with formation of SO_2 and S; when heated it rapidly changes to $\text{H}_2\text{SO}_4\text{Aq}$, SO_2 , and S. The dilute solution is colourless and odourless, and has a sour and bitter taste (*cf. TRITHIONATES*, p. 696). The K salt, from which the acid solution is obtained, may be prepared by dissolving $\text{K}_2\text{S}_3\text{O}_6$ in water containing one-eighth part of alcohol, adding the salt till the alcohol separates from the aqueous solution, passing in SO_2 , with addition from time to time of a little $\text{K}_2\text{S}_3\text{O}_6$, temperature being kept at $25^\circ\text{--}30^\circ$, till the liquid is yellow and smells of SO_2 , setting aside till crystals separate, and re-crystallising from warm water (filtering from separated S) (Plessy, *A. Ch.* [5] 11, 182).

TETRATHIONIC ACID $\text{H}_2\text{S}_4\text{O}_6\text{Aq}$. $\text{PbS}_2\text{O}_6\text{Aq}$ is decomposed by the equivalent quantity of $\text{H}_2\text{SO}_4\text{Aq}$ (not by H_2S , which reacts with $\text{H}_2\text{S}_4\text{O}_6$), and the filtrate from PbSO_4 is concentrated on the water-bath, and then *in vacuo* over H_2SO_4 (Fordos, *C. R.* 115, 920). PbS_2O_6 may be prepared by pouring a solution of 2 pts. $\text{Na}_2\text{S}_2\text{O}_8 \cdot 5\text{H}_2\text{O}$ in much warm water into a dilute warm solution of 8 pts. lead acetate, and thoroughly washing the ppd. PbS_2O_6 with warm water, adding water enough to partially dissolve the PbS_2O_6 , then adding 1 pt. 1, and letting stand for some days, with frequent shaking, filtering from PbI_2 , evaporating and crystallising ($2\text{PbS}_2\text{O}_6 + 2\text{I} + \text{Aq} = \text{PbS}_2\text{O}_6\text{Aq} + \text{PbI}_2$).

$\text{H}_2\text{S}_4\text{O}_6\text{Aq}$ is colourless and odourless; it has a sour taste. Dilute $\text{H}_2\text{S}_4\text{O}_6\text{Aq}$ may be boiled without change, but the conc. solution decomposes to $\text{H}_2\text{SO}_4\text{Aq}$, SO_2 , and S . Dilute HClAq or $\text{H}_2\text{SO}_4\text{Aq}$ does not interact with cold $\text{H}_2\text{S}_4\text{O}_6\text{Aq}$; on warming H_2S is given off; HNO_3Aq or Cl rapidly oxidises $\text{H}_2\text{S}_4\text{O}_6\text{Aq}$ to $\text{H}_2\text{SO}_4\text{Aq}$ (*cf.* TETRATHIONATES, p. 696). Thomsen (*Th.* 2, 262) gives the following data for H.F. :— $[\text{S}^4\text{O}_6\text{Aq}] = 192,430$; $[2\text{SO}_2^2\text{S}_2\text{O}_6\text{Aq}] = 50,270$; $[2\text{SO}_2^2\text{Aq.S}_2\text{O}_6] = 34,870$; $[2\text{S}^4\text{O}_6\text{Aq.O}] = 53,490$.

PENTATHIONIC ACID $\text{H}_2\text{S}_5\text{O}_{10}\text{Aq}$, and **HEXATHIONIC ACID** $\text{H}_2\text{S}_6\text{O}_{12}\text{Aq}$. These acids very probably exist in *Wackenroder's solution* (*v. supra*, p. 698), as salts of $\text{H}_2\text{S}_5\text{O}_{10}$, and probably also of $\text{H}_2\text{S}_6\text{O}_{12}$, have been obtained from that solution; solutions of the acids have not been isolated (*v.* PENTATHIONATES, p. 697, and HEXATHIONATES, p. 697).

M. M. P. M.

THIONINE. The group $\text{S} \begin{array}{c} \text{C}_6\text{H}_5 \\ \text{C}_6\text{H}_4(\text{NH}_2)\text{N} \end{array} \text{NH}$

i.e. $\text{C}_6\text{H}_4(\text{NH}_2) \begin{array}{c} \text{S} \\ \text{N} \end{array} \text{C}_6\text{H}_5\text{NH}$ (Bernthsen & Goske, *B.* 20, 931).

THIONOL $\text{C}_{12}\text{H}_7\text{NSO}_2$, *i.e.* $\text{S} \begin{array}{c} \text{C}_6\text{H}_5 \\ \text{C}_6\text{H}_4(\text{OH})\text{N} \end{array} \text{O}$.

Formed by heating imido-di-phenyl sulphide with dilute H_2SO_4 at 150° – 160° (Bernthsen, *A.* 230, 188). Brownish-red powder, which acquires green lustre on rubbing. Insol. cold water, sol. acids and alkalis, forming a violet solution. Yields di-oxy-imido-diphenyl sulphide (*q. v.*) on reduction.— $\text{B}^+\text{H}_2\text{SO}_4$. Green needles.— B^+BaO (dried at 100°). Plates with green lustre.— $\text{B}^+\text{Ag}_2\text{O}$ (dried at 100°). Brown amorphous pp.

THIONOLINE *v.* OXY-AMIDO-IMIDO-DIPHENYL SULPHIDE.

THIONURIC ACID $\text{C}_4\text{H}_5\text{N}_3\text{SO}_4$, *i.e.*

$\text{CO} \begin{array}{c} \text{NH.CO} \\ \text{NH.CO} \end{array} \text{CH.NH.SO}_2\text{H}$. Formed by the simultaneous action of NH_3 and SO_2 on alloxan in aqueous solution (Liebig & Wöhler, *A.* 26, 268, 814, 381). Formed also by warming nitrosobarbituric acid with ammonium sulphite (Baeyer, *A.* 127, 210). Crystalline mass of needles, *v. sol.* water. Decomposed by boiling water into uramil and H_2SO_4 . Reduces ammoniacal AgNO_3 to a mirror.— $(\text{NH}_4)_2\text{A}^+\text{aq}$. Four-sided tables, *sl. sol.* cold water. At 200° it yields $(\text{NH}_4)_2\text{SO}_4$ and xanthine (Finck, *A.* 182, 298).— $(\text{NH}_4)\text{HA}^+$. White needles.— CaA^+ . Prisms.— PbA^+aq .

THIONYL-*m*-AMIDO-BENZOIC ACID

$\text{SO.N.C}_6\text{H}_4\text{CO}_2\text{H}$. *Methyl ether* MeA^+ . [57°]. (212° at 100 mm.). Formed from methyl *m*-amido-benzoate

and SOCl_2 (Michaelis, *A.* 274, 250). Yellow crystalline mass, *v. sol.* ether and benzene.

Ethyl ether EtA^+ . Oil.

THIONYL-DIAMIDO-DI-PHENYL-ETHYLENE $\text{C}_6\text{H}_4(\text{C}_6\text{H}_4\text{N}_2\text{SO})_2$. [202°]. Formed from di-amido-stilbene and SOCl_2 (Michaelis, *A.* 274, 265). Red needles, *m. sol.* benzene and CHCl_3 .

THIONYL-AMIDO-PHENOL. *Ethyl derivative* $\text{C}_6\text{H}_4(\text{OEt})\text{N.SO}$. [32°]. (220° at 200 mm.). Formed from *p*-amido-phenetol and SOCl_2 (Michaelis, *A.* 274, 246). Light-yellow needles, *v. sol.* ether. Slowly decomposed by water.

THIONYL-AMYLAMINE $\text{SO.NC}_5\text{H}_{11}$. (87° at 60 mm.). Formed from amylamine (103°) in ether and SOCl_2 (Michaelis, *A.* 274, 191). Oil, decomposed by water.

THIONYL-ANILINE $\text{C}_6\text{H}_5\text{N.SO}$. (200°). S.G. $\frac{1.236}{1.238}$. Formed from aniline in benzene solution and SOCl_2 (Michaelis, *B.* 23, 3480; 24, 745). Liquid with peculiar odour, *sol. alcohol*. Converted by alkalis into aniline and sulphite. Chlorine forms tri-chloro-aniline [78°]. Conc. HClAq also forms aniline and SO_2 . The compound $\text{C}_6\text{H}_4\text{Br}_2\text{N.SO}$ [75°] is formed from tri-bromo-aniline in benzene and SOCl_2 . The compounds [$1:2$] $\text{C}_6\text{H}_4\text{Cl}_2\text{N.SO}$ [-8°], [$1:3$] $\text{C}_6\text{H}_3\text{Cl}_3\text{N.SO}$ (233°) and [$1:4$] $\text{C}_6\text{H}_2\text{Cl}_4\text{N.SO}$ [36°] (287°) are formed in like manner. *o*-, *m*-, and *p*-Thionyl-bromo-anilines melt at 4° , 32° , and 61° respectively (Michaelis, *A.* 274, 221). Thionyl-tetra-bromo-aniline melts at 78° . Thionyl-*p*-iodo-aniline [54°] and [$4:2:1$] $\text{C}_6\text{H}_3\text{I}_3\text{N.SO}$ [74°] are also crystalline.

Reference.—NITRO-THIONYL-ANILINE.

THIONYL BROMIDE SOBr_2 , *v.* SULPHUR OXYBROMIDES, p. 617.

THIONYL-ISOBUTYLAMINE $\text{C}_4\text{H}_9\text{N.SO}$ *i.e.* $\text{CHMe}_2\text{CH}_2\text{N.SO}$. (116°). Formed from SOCl_2 and isobutylamine in ether (Michaelis, *A.* 274, 191). Liquid, with pleasant smell.

THIONYL CHLORIDE SOCl_2 , *v.* SULPHUR OXYCHLORIDES, p. 617.

THIONYL-CUMIDINE $\text{C}_6\text{H}_4\text{Pr.N.SO}$. (168°). Got from SOCl_2 and the cumidine obtained from isopropyl-benzene by nitration and reduction (Michaelis, *A.* 274, 239). Oil, not decomposed by boiling water.

Thionyl-*p*-cumidine $\text{C}_6\text{H}_4\text{Me}_2\text{N.SO}$. [-10°]. (246°). Oil, *v. sol.* alcohol and ether.

THIONYL-ETHYLAMINE EtN.SO . (73°). Formed by adding SOCl_2 to an ethereal solution of ethylamine cooled below 0° (Michaelis, *B.* 24, 756).

THIONYL-MESIDINE $\text{C}_6\text{H}_4\text{Me}_2\text{N.SO}$. [-11°]. (241°). S.G. $\frac{1.121}{1.121}$. Volatile with steam (Michaelis, *A.* 274, 240).

THIONYL-METHYLAMINE MeN.SO . (59°). Liquid (Michaelis, *A.* 274, 187).

THIONYL-METHYL-ANILINE $\text{SO}(\text{C}_6\text{H}_4\text{NHMe})_2$. [154°]. Formed from SOCl_2 and methyl-aniline in ethereal solution in presence of AlCl_3 (Michaelis & Godchaux, *B.* 23, 3019). Colourless needles, *v. sol. alcohol*. Yields a nitrosamine $\text{SO}(\text{C}_6\text{H}_4\text{NMe.NO})_2$. [171°].

THIONYL-(*a*)-NAPHTHYLAMINE $\text{C}_{10}\text{H}_7\text{N.SO}$. [33°]. (226° at 100 mm.). Formed from (*a*)-naphthylamine in benzene and SOCl_2 (Michaelis, *A.* 274, 253). Reddish yellow needles, slowly converted by water into naphthylamine sulphite.

Thionyl-(β)-naphthylamine [58°]. Needles. The thionyl derivative of bromo-(β)-naphthylamine [63°] melts at 118°.

THIONYL-*o*-NITRO-ANILINE $C_6H_4N_2SO_2$, i.e. $C_6H_4(NO_2).N:SO$. [62°], the *m*-compound melts at 63°, while the *p*-isomeride melts at 70° (Michaelis, A. 274, 225).

THIONYL-NITRO-MESIDINE $C_6H_9N_2SO_2$, i.e. $C_6HMe_2(NO_2).N:SO$. [77°]. Got from nitro-mesidine [74°] (Michaelis, A. 274, 241). Light yellow needles, v. e. sol. benzene.

Thionyl-di-nitro-mesidine. [127°]. Formed from di-nitro-mesidine [198°].

THIONYL-NITRO-NAPHTHYLAMINE $C_{10}H_7(NO_2).N:SO$. Nitro-naphthylamines [191°] and [119°] yield thionyl derivatives melting at 69° and 135° respectively (Michaelis, A. 274, 258).

THIONYL-NITRO-TOLUIDINE $C_6H_4N_2SO_2$, i.e. $C_6H_4Me(NO_2).N:SO$. The compounds from (2,1,4)-nitro-toluidine [75°] and (3,1,4)-nitro-toluidine [114°] melt at 44° and 89° respectively (Michaelis, A. 274, 232).

DI-THIONYL-PHENYLENE-DIAMINE $C_6H_4(N:SO)_2$. The *m*- and *p*-compounds melt at 44° and 116° respectively (Michaelis, A. 274, 261).

THIONYL-PHENYLETHYL-AMINE $PhCH_2.OH_2.N:SO$. (172° at 25 mm.). Liquid, decomposed by water into SO_2 and base. SO_2 passed into its ethereal solution forms amorphous $PhCH_2.OH_2.NH.SO_2.H$, whence benzoic aldehyde yields $PhCH_2.CH_2.N(SO_2.H).CHPh.OH$ [114°] (Michaelis, B. 26, 2167).

THIONYL-PHENYL-HYDRAZINE v. Action of $SOCl_2$ on PHENYL-HYDRAZINE.

THIONYL-PHENYL-PROPYLAMINE $CH_2Ph.CH_2.CH_2.N:SO$. Formed from phenyl-propylamine hydrochloride and $SOCl_2$ (Michaelis a. Jacobi, B. 26, 2161). SO_2 passed into its ethereal solution forms the amorphous compound $NH(SO_2.H).C_6H_4Ph$, which reacts with benzoic aldehyde forming $SO_2.H.N(CHPh.OH).C_6H_4Ph$ [106°].

THIONYL-PROPYLAMINE $PrN:SO$. (104°). Smells like bleaching-powder (Michaelis, A. 274, 190).

THIONYL-TOLUIDINE $C_6H_4Me.N:SO$. Formed from toluidine and $SOCl_2$. The *o*-compound is liquid (184° at 100 mm.). The *m*-compound is liquid (220°). The *p*-isomeride [7°] (c. 224°) may be crystallised by cooling (Michaelis a. Herz, B. 23, 3482; 24, 753; A. 274, 231). The thionyl derivatives of (3,1,4)- and (5,1,2)-bromo-toluidines melt at 47° and 50° respectively.

THIO-ORCIN $C_6H_3Me(SH)_2$. [35°]. Formed by reducing $C_6H_3Me(SO_2Cl)_2$ with tin and $HClAq$ (Gabriel, B. 12, 1640).— $PbC_6H_3S_2$.

THIONYL-XYLIDINE $C_8H_7Me.N:SO$. The (1,2,4)-compound [-9°] (131° at 20 mm.), (1,3,4)-compound (238°), and (1,4,2)-isomeride [-8°] (119° *in vacuo*) are all oily (Michaelis, A. 274, 287). Thionyl-fluoro-xylinine (144° at 45 mm.) is also an oil.

THIO-OXALIC ACID. *Ethyl ether* $C_2H_5SO_2$, i.e. $CO_2Et.CO_2SEt$. (217° cor.). S.G. 2.145. Formed by the action of $Cl.CO.CO_2Et$ on mercaptan (Morley a. Saint, C. J. 43, 400). Colourless liquid with faint odour like garlic. Decomposed by $KOHAq$ into mercaptan, alcohol, and oxalate. Alcoholic KOH (1 mol.) forms $EtSH$ and $CO_2Et.CO_2K$. Water slowly decomposes it, forming oxalic acid, alcohol, and mer-

captan. Dry NH_3 forms mercaptan and $CO_2Et.CONH_2$.

(β)-Thio-oxalic acid $NH_2.CS.CO_2H$. The salt $C_2H_3KNSO_2$ is formed by the action of cold conc. $KOHAq$ on the ethers. It crystallises in needles, v. sol. water and decomposed by evaporating. The free acid is unstable.

Amide of the methyl ether $NH_2.CS.CO_2Me$. [86°]. Formed by passing dry H_2S into $Cy.CO_2Me$ (Weddige, J. pr. [2] 7, 79; 9, 133; 10, 193). Light-yellow crystals, sol. water, alcohol, and ether.

Amide of the ethyl ether $NH_2.CS.CO_2Et$. Mol. w. 133. [64°]. Formed in like manner. Lemon-yellow crystals. Re-converted by boiling with alcohol and $Pb(OH)_2$ into cyanoformic ether. Methylamine and ethylamine form the crystalline compounds $CO(NHMe).CS.NH_2$ and $CO(NHEt).CS.NH_2$ respectively.

Amide of the isobutyl ether $NH_2.CS.CO_2C_4H_9$. [68°]. Lemon-yellow crystals, sl. sol. water.

Di-amide $CO(NH_2).CS.NH_2$. Formed from $CO_2Et.CS.NH_2$ and alcoholic ammonia (Weddige, J. pr. [2] 9, 187). Lemon-yellow needles (from alcohol), sl. sol. water.

Di-thio-oxalic acid. Amide $CS(NH_2).CS(NH_2)$. *Hydrogen rubeanide*. Mol. w. 120. Formed, together with yellow $Cy.CS.NH_2$, by combination of cyanogen with H_2S (Wöhler, P. 3, 177; Vöckel, A. 38, 315). Formed also by passing cyanogen into an alcoholic solution of $NaSH$ and ppg. by HCl (Wollner, J. pr. [2] 29, 129; Ephraim, B. 22, 2305). Prepared by passing H_2S into an ammoniacal solution of $CuSO_4$, which has been decolourised by KCy (Formánok, B. 22, 2655). Small yellowish-red crystals, sl. sol. water, sol. alcohol and ether. Dilute $KOHAq$ forms oxalic acid, conc. $KOHAq$ forms KCy and $KCyS$. Boiling $HClAq$ forms oxalic acid. MeI and $MeOH$ at 150° form SMe_2I . Alcoholic hydroxylamine hydrochloride (2 mols.) forms $O_2(NH_2)_2(NO_2H)_2$ and H_2S . Benzoic aldehyde, acting on a boiling solution, forms a compound [209°] which is apparently

$CHPh \begin{smallmatrix} S \\ \diagup \\ N \end{smallmatrix} \begin{smallmatrix} S \\ \diagdown \\ N \end{smallmatrix} C.C \begin{smallmatrix} S \\ \diagup \\ N \end{smallmatrix} \begin{smallmatrix} S \\ \diagdown \\ N \end{smallmatrix} CHPh$ (Ephraim, B. 24,

1027).— $PbC_2H_3N_2S_2$: orange pp. (Wallach, B. 13, 528). Yields PbS on boiling with water.

Anilide $CS(NHPh).CS(NHPh)$. [133°]. Formed from oxanilide by successive treatment with PCl_5 and H_2S (Wallach, B. 13, 527). Golden plates.

Di-methyl-di-amide $CS(NHMe).CS(NHMe)$. [140°]. Formed from thiocyanic acid, alcohol, and methylamine (Wallach, A. 262, 360). Yellow crystals, sl. sol. alcohol. Converted by $NaOEt$ and propyl chloride into $C(NMe)(SC_2H_5).C(NMe)(SC_2H_5)$ (170°–175°).

Di-ethyl-di-amide $CS(NHEt).CS(NHEt)$. [58°]. Formed in like manner. Yellowish-red crystals, insol. water. Converted by $NaOEt$ and EtI into $C(NEt)(SEt).C(NEt)(SEt)$ (126°–129°).

Di-amyl-di-amide $CS(NHC_4H_9).CS(NHC_4H_9)$. [60°]. Formed from thiocyanic acid, alcohol, and amylamine (Wallach, A. 262, 362). Red prisms.

Di-benzyl-diamide $CS(NHC_6H_5).CS(NHC_6H_5)$. [115°]. Formed

from thiocyanic acid, alcohol, and benzylamine. Yellowish-red crystals, sl. sol. warm alcohol.

Hexa-thio-ortho-oxalic acid. *Ethyl ether* $C_6(SET)_6$. Formed from O_2Cl_2 and $NaSET$ (Claesson, *J. pr.* [2] 15, 212). Heavy oil.

THIO-OKY- v. SULPHYDRO-.

THIO-PARABANIC ACID. *Methyl derivative v. METHYL-THIO-PARABANIC ACID-.*

Allyl derivative $C_6H_4N_2SO_2$ i.e.

$CS \langle \begin{smallmatrix} NH_2 \\ N(C_2H_5) \end{smallmatrix} \rangle CO$. *Oxalyl-thio-sinamine.*

[90°]. Formed by warming the dicyanide of allyl-thio-urea with dilute H_2SO_4 (Maly, *Z.* 1869, 260). Lemon-yellow needles, m. sol. cold water.

THIOPHENE C_6H_4S i.e. $S \langle \begin{smallmatrix} CH:CH \\ CH:CH \end{smallmatrix} \rangle$ (84° cor.). V.D. 3.0 (calc. 2.9). S.G. 1.062; $\frac{1}{4}$ 1.0884; $\frac{1}{2}$ 1.0705 (R. Schiff, *B.* 18, 1601). S.V. 84.9. R_{∞} 41.4 (Nasini a. Scala, *G.* 17, 70). H.C.p. 670,900 (Berthelot a. Matignon, *C. R.* 111, 10; *Bl.* [3] 4, 252). H.F.—14900. *Critical temperature* 317° (Pawlewski, *B.* 21, 2141). *Critical pressure* 47.7 atmospheres. Occurs in coal-tar benzene to the extent of about .5 p.c. (V. Meyer, *B.* 16, 1471).

Formation.—1. In small quantity by passing acetylene through boiling sulphur (V. Meyer a. Sandmeyer, *B.* 16, 2176).—2. By heating succinic anhydride with P_2S_5 .—3. By heating sodium succinate with P_2S_5 , the yield being 50 p.c. of the theoretical amount (Volhard a. Erdmann, *B.* 18, 454). It is not formed by heating *s*-di-bromo-succinic acid with P_2S_5 , or P_2S_3 (Ossipoff, *J. R.* 20, 245).—4. By heating erythrite with P_2S_5 (Paal a. Tafel, *B.* 18, 688).—5. From its (α)-carboxylic acid, which is obtained by heating mucic acid with BaS (Paal a. Tafel, *B.* 18, 456).—6. In small quantities by passing Et_2S through a red-hot tube (Meyer, *B.* 18, 217).—7. In small quantities by passing ethylene, coal-gas, or ligroin-vapour over heated iron pyrites.—8. In small quantities by heating P_2S_5 with crotonic acid, with *n*-butyric acid, with paraldehyde, or with ether (Meyer).

Isolation.—20 pts. commercial 'pure' benzene is shaken for four hours with 1 pt. of H_2SO_4 . The acid is diluted with two or three times its weight of water and treated at once with steam. Nearly pure thiophene passes over. Yield, about $\frac{3}{4}$ p.c. by volume of the H_2SO_4 used (Schulze, *B.* 18, 497).

Properties.—Liquid with faint odour, not decomposed below 335°. Not solid at -20°. Greatly resembles benzene. Oxidised by HNO_3 with great violence. On shaking with isatin and H_2SO_4 , it yields a blue colouring matter (indophenine). Not affected by boiling with sodium. Benzene that contains thiophene gives a bright-blue colour to H_2SO_4 , containing nitrous acid. Thiophene (10 g.) shaken with alcohol (100 g.), cold saturated $HgCl_2$ solution (1,000 g.), and $NaOAc$ (70 g.) dissolved in water (180 g.) forms a white pp. containing $C_6H_4(HgCl)_2S$, which crystallises from alcohol in white plates [188°], and $C_6H_4(HgCl)_2S$, a white powder, insol. alcohol (Volhard, *A.* 267, 172). The compound $C_6H_4(HgCl)_2S$ is converted by $AcCl$ into α -thienyl methyl ketone and by I into di-iodo-thiophene. Thiophene combines with $CHPh$, and with di-bromo-di-(β)-naphthyl oxide (Liebmann, *B.* 26, 858).

Reactions.—1. *Chloral* and H_2SO_4 yield $CCl_3.CH(C_6H_4S)_2$.—2. $BzCl$ and $AlCl_3$ form thienyl phenyl ketone.—3. *Phenyl-glyoxylic acid* and H_2SO_4 form $C_{12}H_8NSO_2$, which dissolves in chloroform with crimson, and in H_2SO_4 with purple colour.—4. Cl and Br yield chloro- and bromo- derivatives.—5. H_2SO_4 forms a brown solution containing a sulphonic acid, and slowly decomposes the thiophene, forming H_2S , SO_2 , and an amorphous pp.—6. H_2SO_4 and KNO_3 form a compound called 'nitroso-dithiophene'

$HO.N \langle \begin{smallmatrix} C_6H_4S \\ C_6H_4S \end{smallmatrix} \rangle O$ (?), ppd. by water as a dark insoluble powder (Liebmann, *B.* 20, 3231).—7. Passed with PCl_5 through a red-hot tube it forms $C_6H_4S.PCl_2$ (218°) which is decomposed by water into $C_6H_4S.P(OH)_2$ [70°] and is converted by Cl into $C_6H_4S.PCl_2$, which is converted by SO_2 into $C_6H_4S.POCl_2$ (259°) and by water into $C_6H_4S.PO(OH)_2$ [159°] (Sachs, *B.* 25, 1514).—8. *Diazobenzene chloride* and $AlCl_3$ forms (β)-phenyl-thiophene [57°] (Möhlau a. Berger, *B.* 26, 2001).

References.—AMIDO-, BROMO-, DI-BROMO-DI-NITRO-CHLORO-, TRI-CHLORO-NITRO-, IODO-, IODO-NITRO-, and NITRO- THIOPHENE.

THIOPHENE (α)-CARBOXYLIC ACID

$C_6H_4SO_2$ i.e. $S \langle \begin{smallmatrix} CH=CH \\ O(CO_2H):CH \end{smallmatrix} \rangle$ Thiophene ' β '.

carboxylic acid. [126.5°]. (260° cor.). H.F. 85,400. H.C.p. 591,900 (Stohmann, *J. pr.* [2] 43, 12). Formed by adding sodium-amalgam to a mixture of $Cl.CO_2Et$ with (α)-iodothiophene, with di-iodo-thiophene, or with di-bromo-thiophene (Nahnsen, *B.* 17, 2192; 18, 2304; Bonz, *B.* 18, 2306). Formed also by heating mucic acid with BaS for 6 hours at 205°, the yield being 12 p.c. of the theoretical (Paal a. Tafel, *B.* 18, 456). Obtained by oxidation of (α)-ethyl-thiophene (Schleicher, *B.* 18, 3017), of (α)-propyl-thiophene (Ruff, *B.* 20, 1740), of thienyl methyl ketone (Peter, *B.* 17, 2645; 18, 542), and of thienyl ethyl ketone (Ernst, *B.* 20, 518) with alkaline $KMnO_4$.

Properties.—Slender white needles (from water) or long flat needles (by sublimation), v. sol. hot water, sl. sol. cold, v. e. sol. alcohol and ether, m. sol. chloroform, sl. sol. ligroin. Gives a blue colour on warming with isatin and H_2SO_4 (indophenine reaction). Yields thiophene on distilling with lime. Yields a di-bromo-derivative [211°].

Salts.— BaA' , 2aq. Small crystals. S. 22-19 at 14.5°.— CaA' , 3aq. S. 18.5 at 18.5°.— ZnA' , (dried). S. 14 at 15°.— PbA' , (dried) .5 at 18.5°.— AgA' : plates or needles. S. .195 at 11°.

Ethyl ether EtA' . (218° cor.). S.G. 22 1.1155. Liquid, smelling like benzoic ether.

Chloride $C_6H_4S.COCl$. (190° uncor.). Liquid, smelling like benzoyl chloride.

Amide $C_6H_4S.CONH_2$. [174°] (Meyer, *A.* 236, 210). Prisms, m. sol. ether. Phenyl thiocarbimide forms $C_6H_4S.CO.NH.CO.NHPh$. [206°]

Anilide $C_6H_4S.CONHPh$. [140°]. Formed by the action of phenyl cyanate on thiophene in presence of $AlCl_3$ (Leuchart a. Schmidt, *B.* 18, 2340). Iridescent plates.

Amidoxim $C_6H_4S.C(OH).NH_2$. [92°]. Formed by the action of hydroxylamine on the

nitrile (Meyer, *A.* 236, 213). Long prisms (from benzene).

Nitrile (192°) (D.); (200° cor.) (Peter, *B.* 18, 543). Formed by distilling thienyl-glyoxylic acid with aqueous hydroxylamine (Douglas, *B.* 25, 1311).

Tetrahydride $S < \begin{smallmatrix} \text{CH}(\text{CO}_2\text{H})\cdot\text{CH}_2 \\ \text{CH}_2 \end{smallmatrix} \text{CH}_2$. [51°].

H.F. 114,900. H.C.p. 700,400. Formed by reducing the acid, in alkaline solution, with sodium-amalgam (Ernst, *B.* 19, 3278; 20, 518). Plates or needles (from ligroin), v. e. sol. water and alcohol, v. sol. ether. Volatile with steam. Much decomposed on distillation. Reduces ammoniacal AgNO_3 . Salts.— CaA'_2 3aq. Crystalline, sol. water.— AgA' . M. sol. water. *Methyl ether* $\text{Me}_2\text{A}'$. (c. 206°). *Ethyl ether* EtA' . Liquid.

Thiophene (β)-carboxylic acid

$S < \begin{smallmatrix} \text{CH}:\text{CH} \\ \text{CH}:\text{C}\cdot\text{CO}_2\text{H} \end{smallmatrix}$ (γ)-Thiophenic acid. [136°].

S. 44 at 17°. Formed by the action of alkaline KMnO_4 on (β)-methyl-thiophene (Muhler, *B.* 18, 3003) or (β)-ethyl-thiophene, the yield being about 8 p.c. (Damsky, *B.* 19, 3284). Needles (from water), sol. ether, volatile with steam. Gives the indophenine reaction.— CaA'_2 3aq. S. (of CaA'_2) 7.92 at 14.5°.— BaA'_2 (dried). S. 11.54 at 17°.— AgA' . Needles or plates, v. sl. sol. Aq.

Amide $\text{C}_4\text{H}_5\text{S}\cdot\text{CONH}_2$. [178°]. Converted by phenyl cyanate into $\text{C}_4\text{H}_5\text{S}\cdot\text{CO}\cdot\text{NH}\cdot\text{CO}\cdot\text{NHPh}$. [206°].

Thiophene 'a'-carboxylic acid. [118°]. (258° cor.). This is a mixture of the (α)- and (β)-acids. It is got by saponifying the mixed nitrile which is formed by distilling a mixture of potassium thiophene (α) and (β) sulphonates with KCy (V. Meyer, *B.* 16, 2174; 18, 2815; Bonz, *B.* 18, 2308). Formed also by oxidising a mixture of (α)-methyl-thiophene (2 pts.) and (β) methyl-thiophene (3 pts.) and by slow evaporation of an aqueous solution of the mixed thiophene carboxylic acids in the cold (Egli, *B.* 18, 548; V. Meyer, *B.* 19, 2891; *A.* 236, 221). Volatile with steam. Can be separated into the (α)- and (β)-acids by crystallisation.

Thiophene dicarboxylic acid

$S < \begin{smallmatrix} \text{CH}=\text{CH} \\ \text{C}(\text{CO}_2\text{H})\cdot\text{C}(\text{CO}_2\text{H}) \end{smallmatrix}$. [270°]. Formed by oxidising the corresponding di-methyl-thiophene with alkaline KMnO_4 (Grünwald, *B.* 20, 2586). Formed also by oxidising (β)-methyl-thienyl methyl ketone (Gerlach, *A.* 267, 153). Long needles (from water), v. e. sol. ether. Not volatile with steam. Resorcin at 200° forms a fluorescein which exhibits yellowish-green fluorescence in alkaline solution.— PbA'' .— BaA'' . Crystals, sl. sol. cold water.— AgA'' . White pp. *Methyl ether* $\text{Me}_2\text{A}''$. [59.5°]. Plates.

Thiophene dicarboxylic acid

Formation.—1. By oxidation by alkaline KMnO_4 of di-methyl-thiophene from coal tar (Messinger, *B.* 18, 567), from (α)-ethyl-thienyl methyl ketone, from (α)-ethyl-thiophene (α)-carboxylic acid (Schleicher, *B.* 18, 8020), from methyl-thienyl methyl ketone (Demuth, *B.* 18, 3025), and from (α)-methyl-thiophene carboxylic acid (Levi, *B.* 19, 656).—2. By saponifying its nitrile, which may be got by fusing potassium

thiophene disulphonate with KCy (Jaekel, *B.* 19, 191).—3. By saponifying its ether which is got by the action of sodium-amalgam on a mixture of di-bromo-thiophene and ClCO_2Et (Bonz, *B.* 18, 2306).

Properties.—Crystalline powder, v. sl. sol. cold water, sol. ether. Not melted at 300°. Does not give the fluorescein reaction.

Salts.— BaA'' aq. Crystalline, v. sl. sol. cold water.— CaA'' 3aq.— $\text{Ag}_2\text{A}''$: white pp.

Methyl ether $\text{Me}_2\text{A}''$. [145°] (J.); [147°] (S.); [151°] (D.). White needles from alcohol.

Ethyl ether EtA'' . [47°] (J.); [52°] (S.). Long needles (from alcohol).

Nitrile $\text{C}_4\text{H}_4\text{SCy}_2$. [92°]. Crystals.

Tetrahydride $S < \begin{smallmatrix} \text{CH}(\text{CO}_2\text{H})\cdot\text{CH}_2 \\ \text{CH}(\text{CO}_2\text{H})\cdot\text{CH}_2 \end{smallmatrix}$. [162°

cor.]. Formed by reducing the acid in alkaline solution by sodium-amalgam (Ernst, *B.* 19, 3275). Plates, v. sol. water, sol. ether. Reduces hot ammoniacal AgNO_3 . Hot conc. H_2SO_4 evolves CO (1 mol.).— BaA'' : scales.— $\text{Ag}_2\text{A}''$: white powder.— $\text{Me}_2\text{A}''$. Oil.

Thiophene dicarboxylic acid

$S < \begin{smallmatrix} \text{CH}=\text{C}\cdot\text{CO}_2\text{H} \\ \text{C}(\text{CO}_2\text{H})\cdot\text{CH} \end{smallmatrix}$. Formed by oxidation of the corresponding di-methyl-thiophene by alkaline KMnO_4 (Zelinsky, *B.* 20, 2022). Needles, sl. sol. cold water. Decomposes and partially sublimates at 280°, v. sol. hot water.— AgA'' .

Methyl ether $\text{Me}_2\text{A}''$. [121°]. Plates.

Ethyl ether EtA'' . [36°].

Thiophene tri-carboxylic acid $\text{C}_4\text{SH}(\text{CO}_2\text{H})_3$. Formed by oxidation of di-methyl-thienyl methyl ketone with KMnO_4 (Messinger, *B.* 18, 2302).

Methyl ether $\text{Me}_3\text{A}''$. [118°]. Plates, v. sol. alcohol and ether.

References.—BROMO- and IODO- THIOPHENE CARBOXYLIC ACID and NITRO-THIOPHENIC ACID.

THIOPHENE GREEN $\text{C}_8\text{H}_5\text{N}_2\text{S}$. The leuco-base $\text{C}_8\text{SH}_2\cdot\text{CH}(\text{OH})(\text{C}_6\text{H}_4\text{NMe}_2)_2$ is got by heating thiophenic aldehyde with di-methyl aniline, ZnCl_2 , and a little alcohol at 100° (Levi, *B.* 20, 513). It crystallises in needles [93°], and is readily oxidised to thiophene green $\text{C}_8\text{SH}_2\cdot\text{C}(\text{OH})(\text{C}_6\text{H}_4\text{NMe}_2)_2$, which is an oil and forms the salts $(\text{C}_2\text{H}_5\text{N}_2\text{S})\cdot\text{ZnCl}_2$ 2aq, $\text{B}'\text{H}_2\text{SO}_4$, $\text{B}'_2\text{H}_2\text{C}_2\text{O}_4$ 2aq, and $\text{B}'_2\text{C}_6\text{H}_8\text{N}_2\text{O}_6$, crystallising in scales with coppery lustre.

Leuco-thiophene green v. TETRA-METHYL-DI-AMIDO-DI-PHENYL-THIENYL-METHANE.

THIOPHENE (α)-SULPHINIC ACID

$\text{C}_4\text{H}_5\text{S}\cdot\text{SO}_2\text{H}$. [67°]. Formed by the action of zinc-dust on an alcoholic solution of thiophene sulphonic chloride (Weitz, *B.* 17, 800). Needles, v. sol. water, alcohol, and ether. Gives the indophenine reaction.— BaA'_2 2aq. White plates, v. sol. water.— ZnA'_2 3aq.— AgA'_2 . Crystalline pp.

THIOPHENE ' α '-SULPHONIC ACID

$\text{C}_4\text{H}_5\text{S}\cdot\text{SO}_3\text{H}$. Formed by shaking thiophene (20 g.) dissolved in ligroin (2,000 c.c.) with H_2SO_4 (300 c.c.) for 2 hours (V. Meyer & Kreis, *B.* 16, 2172; Biedermann, *B.* 19, 1615). Deliquescent mass. Yields thiophene on distillation. It is doubtless a mixture of the (α) and (β) acids.— NaA' aq.— BaA'_2 3aq.— CaA'_2 .— PbA' aq. Very soluble powder.— AgA' 3aq. Plates (Weitz, *B.* 17, 796).

Ethyl ether EtA' . Oil.

Chloride $\text{C}_4\text{H}_5\text{S}\cdot\text{SO}_2\text{Cl}$. [28°]. (above 200°). Oil or colourless crystals.

Amide $C_4H_3S.CONH_2$. [142°] (Langer, B. 17, 1568). Needles (from water).— $C_4H_3S.CO.NHAg$. Pearly scales.

Anilide $C_4H_3S.CONHPh$. [96°].

Thiophene (β)-sulphonic acid

$\begin{matrix} CH:CH \\ S < CH:C(SO_3H) \end{matrix}$ Formed by the action of sodium-amalgam on di-bromo-thiophene (β)-sulphonic acid, which is got by sulphonation of di-bromo-thiophene (Langer, B. 17, 1567; 18, 553). Obtained in like manner from iodo-thiophene sulphonic acid, and from tri-bromo-thiophene sulphonic acid (Rosenberg, B. 18, 1776). Crystalline solid, v. sol. water. Gives a blue colour with isatin and H_2SO_4 .— BaA' .
Chloride $C_4H_3S.SO_2Cl$. [43°]. Plates, v. sol. ether, insol. ligroin.

Amide $C_4H_3S.SO_2NH_2$. [148°]. Tables.

Thiophene disulphonic acid $C_4H_2S(SO_3H)_2$. Formed by reduction of di-bromo-thiophene ' β '-di-sulphonic acid by sodium-amalgam (Langer, B. 18, 554, 1114; Rosenberg, B. 18, 3030). Crystalline, v. sol. water.— BaA'' 2 $\frac{1}{2}$ aq.

Chloride $C_4H_2S(SO_2Cl)_2$. [149°]. Scales.

Amide $C_4H_2S(SO_2NH_2)_2$. [c. 280°]. Needles.

Thiophene disulphonic acid $C_4H_2S(SO_3H)_2$. Formed by reducing iodo-thiophene ($\alpha\beta$)-disulphonic acid with sodium-amalgam (Langer, B. 18, 560).

Amide $C_4H_2S(SO_2NH_2)_2$. [142°]. Plates. Gives the indophenine reaction.

Thiophene disulphonic acid $C_4H_2S(SO_3H)_2$. Formed from lead thiophene sulphonate and fuming H_2SO_4 (Jaekel, B. 19, 185, 1066). Crystalline, v. sol. water and alcohol.— K_2A' aq; prisms, v. sol. water.— NaA'' 3aq. Needles, v. sol. water.— BaA'' 3aq. Flat prisms, sl. sol. water.— CuA' 4aq. Blue needles.— AgA'' .

Chloride $C_4H_2S(SO_2Cl)_2$. [77.5°]. Needles (from ether).

Amide $C_4H_2S(SO_2NH_2)_2$. [211.5].

References.—Di-bromo-, Iodo- and Nitro-THIOPHENESULPHONIC ACID.

THIOPHENIC ACID v. THIOPHENECARBOXYLIC ACID.

THIOPHENIC ALDEHYDE $C_4H_3S.CHO$. (198° cor.). S.G. 21.1-215. Formed by distilling (α)-thienyl-glyoxylic acid (Biedermann, B. 19, 687, 1853). Formed also by the action of H_2S on $CHCl \begin{matrix} CH_2 \\ CO.OO \end{matrix}$ (Hantzsch, B. 22, 2838).

Oil, smelling like benzoic aldehyde. Oxidised by air to thiophene (α)-carboxylic acid.

Oxim $C_4H_3S.CH(OH)$. Thiophene *synal-doxim*. [128°]. Needles (from ether). Converted by $NaOHAq$ into thiophene carboxylic nitrile (Hantzsch, B. 24, 47). Yields an acetyl-derivative [75°-80°]. $NaOMe$ and MeI in $MeOH$ yield $C_4SH_3CH \begin{matrix} NMe \\ O \end{matrix}$ [120°], crystallising in tables; converted by dilute H_2SO_4 into the aldehyde and (β)-methyl-hydroxylamine (Goldschmidt a. Zanoli, B. 25, 2588). Phenyl cyanate in ether forms $C_4SH_3.CH:NO.CO.NHPh$ [70°], crystallising in needles.

Oxim $C_4H_3S.CH.NOH$. Thiophene *anti-aldoxim*. Formed by the action of hydroxylamine hydrochloride, $NaOHAq$ and Na_2CO_3 on the aldehyde (Goldschmidt a. Zanoli, B. 25, 2590). Converted by phenyl cyanate into $C_4SH_3.CH:NO.CO.NHPh$ [144°], whence $NaOH$

forms $C_4SH_3.CH:N.NHPh$ [46°]. *o*-Tolyl cyanate forms $C_4H_3S.CH:NO.CO.NH.C_6H_5$, [66°].

Phenyl hydrazide $C_4SH_3.CH:N.NHPh$. [134-5°]. Needles (from alcohol).

THIOPHENIC IMIDO-ETHYL ETHER

$C_4H_3S.C(OEt):NH$. The salt $B'HCl$ is formed by the action of dry HCl on the nitrile of thiophene carboxylic acid (Douglas, B. 25, 1312). It is crystalline, and is converted by hydroxylamine into $C_4H_3S.C(OEt):NOH$ [67°].

THIOPHENINE is AMIDO-THIOPHENENE.

THIOPHENOL v. PHENYL MERCAPTAN.

THIOPHENURIC ACID $C_4H_3NSO_3$. [172°].

Excreted in the urine of rabbits after injection of sodium thiophene (α)-carboxylic acid (Jaffé a. Levi, B. 21, 3458). Prisms, resembling hippuric acid (from water), v. sl. sol. ether, v. sol. alcohol. Split up by boiling baryta-water into glycocoll and thiophene (α)-carboxylic acid.— BaA' 2aq. Needles, v. sol. water.— CaA' 2aq.— AgA' .

THIO-PHENYL-ACETIC ACID. *Amide*

$C_6H_5.CH_2.CO.SNH_2$. [98°]. Formed by heating phenyl-acetamide (3 pts.) with P_2S_5 (2 pts.), and also by allowing a solution of phenyl-acetonitrile in alcoholic ammonium sulphide to stand for some days (Bernthsen, B. 11, 503; A. 184, 292). Trimetric crystals (from alcohol), decomposed on distillation into H_2S and $C_6H_5.CH_2.CN$.

Reactions.—1. Boiling NH_4Aq forms phenyl-acetamide. —2. HgO forms phenyl-acetonitrile. —3. Zn and $HClAq$ form phenyl-ethyl-amine (Colombo a. Spica, B. 8, 821). —4. *Benzoic aldehyde* forms oily $C_{12}H_{12}N_2S_2$ (?). —5. *Sodium-amalgam* forms $Ph.CH_2.CH.NH_2$ and a compound $C_{12}H_{12}NS_2$ [108°]. —6. *Iodine* added to a hot alcoholic solution forms $C_{10}H_8N_2S$ [42°]. —7. MeI forms $(CH_2Ph.C(NH).SMe)HI$ [139°], which gives rise to $(C_6H_5NS)_2H_2PtCl_6$. —8. EtI forms $(C_6H_5NS)HI$ [116°], which is v. e. sol. water, and yields, on treatment with $NaOHAq$, the free base $CH_2Ph.C(NH).SEt$, which is an oil that quickly decomposes into mercaptan and phenyl-acetonitrile. The salts $(C_6H_5NS)HCl$ [c. 120°], $B'_2H_2PtCl_6$ [below 180°], and $B'HI$ are crystalline. —9. *Aniline* forms the compound $CH_2Ph.C(NH_2).NPh$.

THIO-PHENYL-ALLOPHANIC ACID v. PHENYL-THIO-ALLOPHANIC ACID.

THIO-DI-PHENYL-AMINE v. IMIDO-DI-PHENYL SULPHIDE.

THIO-PHENYL-CARBAMIC ACID v. PHENYL-THIO-CARBAMIC ACID.

THIO-DI-PHENYL KETONE v. THIO-BENZOPHENONE.

THIO-DI-PHENYL-METHYL-AMINE v. METHYL-IMIDO-DI-PHENYL SULPHIDE.

DI-THIO-PHTHALIC ACID $C_4H_2(CO.SH)_2$. The salt K_2A'' is formed by dissolving KSH (2 mols.) in an alcoholic solution of phenyl phthalate (1 mol.). The free acid splits up at once into H_2S and thiophthalic anhydride (Schreder, B. 7, 706).

(α)-Di-thio-isophthalic acid. The K salt, formed by the action of KSH on phenyl isophthalate, crystallises in yellow needles.

Ethyl ether Et_2A'' . Formed by adding water to the hydrochloride of $C_4H_2(C(NH).SEt)_2$ (Luckenbach, B. 17, 1435). Small needles.

(β)-Di-thio-isophthalic acid. *Amide* $C_4H_2(CSNH_2)_2$. [200°]. Formed by heating isophthalic nitrile with alcoholic ammonium

sulphide (L.). Needles, sol. hot alcohol. Reconverted into the nitrile by lead acetate. Boiling KOHAq forms isophthalic acid.

THIO-PHTHALIC ANHYDRIDE $C_6H_4SO_2$, *i.e.*

$C_6H_4\langle\begin{smallmatrix} \text{CO} \\ \text{CO} \end{smallmatrix}\rangle S$. [114°]. (284°). Formed by the action of KSH on phthalyl chloride, or on phenyl phthalate (Graebe & Zschokke, *B.* 17, 1175). Formed also by the action of As_2S_3 on phthalyl chloride (Rayman, *Bl.* [2] 47, 898). Plates, v. sol. hot alcohol, ether, and chloroform, sl. sol. water. Volatile with steam. Sol. alkalis and converted by long boiling with alkalis into phthalic acid. Ammonia forms phthalimide. Resorcin and H_2SO_4 give a thiouresorcin, the alkaline solution of which is deep red with green fluorescence.

THIO-PHTHALIDE $C_6H_4\langle\begin{smallmatrix} \text{CO} \\ \text{CO} \end{smallmatrix}\rangle S$. [57°].

Formed by heating $C_6H_4Cy.CH_2.SCy$ with conc. HClAq for 5 hours at 180° (Day & Gabriel, *B.* 28, 2480). Thin needles (from dilute alcohol).

THIO-PHTHALIMIDINE C_6H_4NS , *i.e.*

$C_6H_4\langle\begin{smallmatrix} \text{C(NH)} \\ \text{CH}_2 \end{smallmatrix}\rangle S$ or $C_6H_4Cy.CH_2.SH$. [62°].

Formed by warming *o*-cyano-benzyl sulphocyanide with H_2SO_4 at 65° (Day & Gabriel, *B.* 23, 2481). Formed also by adding KSHAq to *o*-cyano-benzyl chloride in alcohol. Needles, which darken in air, v. sol. alcohol and ether. Boiling NaOHAq forms thiophthalide. KSH added to its alcoholic solution forms $C_6H_4S_2$, crystallising from nitrobenzene in needles with green lustre. — $B'HCl$. Needles. — $B'_2H.PtCl_6$. Orange-yellow prisms. — $B'HI$. Needles. — Picrate: slender needles.

THIOPHTHENE $C_6H_4S_2$, *i.e.* $\begin{smallmatrix} \text{CH} - \text{C} - \text{CH} \\ \text{CH.S.C.S.CH} \end{smallmatrix}$

(225° cor.). Formed by distilling citric acid (1 pt.) with P_2S_5 (2 pts.), adding NaOHAq, and distilling with steam (Biedermann & Jacobson, *B.* 19, 2444). Oil, not solid at -10°. Gives the indophenine reaction. — $B'_2C_6H_4N_2O_6$. [138°]. Yellow needles, v. sol. alcohol and benzene.

Reference.—TETRA-BROMO-THIOPHTHENE.

THIOPHYLLINE $C_8H_8N_2O_2$. [264°].

Occurs in small quantity, in extract of tea (Kossel, *B.* 21, 2164). Crystals (containing aq), more sol. water and alcohol than theobromine, v. sol. NH_4Aq . Forms salts with acids. On evaporation with chlorine-water it leaves a scarlet residue, turned violet by NH_4Aq . — $C_8H_8AgN_2O_2$. Amorphous, converted by MeI into caffeine $C_8H_{10}N_4O_2$. [229°].

(α)-**THIO-PROPIONIC ACID** C_3H_5OS .

Methyl ether $CH_3.CH_2.CO.SMe$. (120°). V.D. 51.28. Formed from propionyl chloride and lead mercaptide in the cold (Obermeyer, *B.* 20, 2922).

(β)-Thio-propionic acid $Et.CO.SH$. The salt NaA' formed by boiling propionitrile with alcoholic ammonium sulphide is crystalline (Dupré, *Bl.* [2] 29, 804).

Amide $EtC(NH).SH$. [42°]. Formed by heating propionamide (5 mols.) with P_2S_5 (1 mol.) in benzene for a short time (Hubacher, *A.* 259, 229). Yellowish plates, v. e. sol. benzene.

THIO-ISOPROPYL-COUMARIN $C_{11}H_{10}SO$, *i.e.*

$C_6H_4\langle\begin{smallmatrix} \text{CH}_2.C(C_2H_5) \\ \text{O} - \text{CS} \end{smallmatrix}\rangle$. [81°]. Formed by heating isopropyl-coumarin with P_2S_5 at 120° (Aldringen,

B. 24, 8463). Reddish-yellow needles, sol. hot alcohol, sl. sol. ether.

THIO-PRUSSIAMIC ACIDS. By heating ammonium sulphocyanide there is formed, besides thio-urea, dithiodiprussiamic acid $C_6H_4N_4S_2$, a yellowish-white powder, sl. sol. hot water; thiodiprussiamic acid $C_6H_4N_4S$, amorphous, m. sol. hot water; and ammonium dithiotripussiamate $C_6H_4N_4S_2$, which crystallises from water. The first acid gives no colour with $FeCl_3$, the two other bodies give a red colour. The lead salts of these acids dissolve in hot water.

THIOTETRAPYRIDINE, so called, $C_{20}H_{12}N_4S$ (?). [155°]. Formed by heating nicotino (1 pt.) with sulphur (6 pts.) at 150° till the mass is chrome-green (Cahours & Etard, *Bl.* [2] 34, 452). Yellow prisms (from alcohol). — B'_2HCl . — $B'HHgCl_2$. — $B'H.PtCl_6$: yellow amorphous pp.

THIO- PYROCATECHIN v. OXY-PHENYL MERCAPTAN.

THIO-PYROMUCIC ACID. *Amide*

$C_6H_4O.CO.SNH_2$. [127°]. Formed by passing H_2S into a solution of furfuronitrile in alcohol-ether (Douglas, *B.* 25, 1814). Yellowish crystals, sl. sol. cold water, v. sol. alcohol.

THIO-PYRUVIC ACID. The compound $(C_2H_3O_2S)C_2H_3O_2$, [87°] separates as a powder when H_2S is passed into pyruvic acid (Böttger, *A.* 188, 325). It is v. e. sol. water and is converted by boiling HIAq into $CH_3.CH(SH).CO_2H$. Boiling water forms H_2S and thiopyruvic acid.

DI-THIO-RESORCIN $C_6H_4(SH)_2$. Mol. w. 142. [27°]. (243°). Formed by reducing the sulphochloride $C_6H_4(SO_2Cl)_2$ with tin and HClAq (Patschke, *J. pr.* [2] 2, 418; Körner, *G.* 6, 140). Crystals, smelling like some geraniums. $Pb(OAc)_2$ added to its alcoholic solution ppts. orange $C_6H_4S_2Pb$, whence MeI forms $C_6H_4(SMe)_2$ (278°) (Obermeyer, *B.* 20, 2927).

THIO-BUFIC ACID $C_{10}H_{14}S_2O_4$. Formed by the action of CS_2 on a mixture of NaOEt and acetoacetic ether (Norton & Oppenheim, *B.* 10, 701). Pearly orange scales, nearly insol. water. — NaA' : brick-red needles. — CaA' : red needles.

THIO SALICYLIC ACID v. OXY-THIO-BENZOIC ACID.

THIOSINAMINE v. ALLYL-THIO-UREA.

THIO-SUCCINIC ACID. *Anhydride*

$C_2H_4\langle\begin{smallmatrix} \text{CO} \\ \text{CS} \end{smallmatrix}\rangle O$. 'Sulphosuccinyl'. [31°]. (225°).

Formed by adding succinyl chloride dissolved in benzene or CS_2 to an aqueous solution of Na_2S . Got also by distilling succinic acid (100 g.) with P_2S_5 (100 g.) (Auger, *A. Ch.* [6] 22, 353). White crystals. Its aqueous solution gives off H_2S on heating. Phenylhydrazine forms $CO_2H.C_6H_4.C(SH).N.NHPb$ [120°] and $C_2H_4\langle\begin{smallmatrix} \text{CO} \\ \text{C(N.HPh)} \end{smallmatrix}\rangle O$ [216°], which on distillation changes to succinyl-phenyl-hydrazine [155°]. Phenyl-hydrazine also produces $C_6H_4(CO.N.HPh)_2$ [219°] (Zanetti, *C. C.* 1889, 668). Sodium-amalgam forms $C_6H_4NaSO_2$, converted by phenyl-hydrazine acetate into $CO_2H.C_6H_4.CH.N_2HPh$ [c. 175°].

Di-thio-succinic acid $C_2H_4(CO.SH)_2$. The salt K_2A' , got by boiling succinyl-phenol with KSH in alcohol, crystallises in minute needles, v. sol. water, alcohol, and ether (Weselsky, *B.* 2, 518). Its aqueous solution is decomposed by spontaneous evaporation. Acids

split it up into H_2S and thiosuccinic anhydride (*v. supra*).

Ethyl ether $\text{C}_6\text{H}_4(\text{CO.SEt})_2$. (271°). Formed from di-phenyl succinate (42 g.) and sodium mercaptide (30 g.) in dry ether in the cold (Seiffert, *J. pr.* [2] 31, 469). Oil, smelling of garlic.

THIO-SUCCINURIC ACID $\text{C}_4\text{H}_4\text{N}_2\text{SO}_4$. [211°]. Formed by heating succinic anhydride with thio-urea at 140° (Pike, *B.* 6, 1105). Yellowish powder, insol. alcohol and ether, sl. sol. water and HOAc . Decomposed by alkalis into thio-urea and succinic acid.

(a) - **DI - THIO - TEREPHTHALIC ACID** $\text{C}_6\text{H}_4(\text{CS.NH}_2)_2$. Formed by the action of alcoholic KSH on di-phenyl terephthalate (Schreder, *B.* 7, 708). Amorphous, v. sl. sol. alcohol.

(b) - **Di - thio - terephthalic acid. Amide** $\text{C}_6\text{H}_4(\text{CS.NH}_2)_2$. [263°]. Formed by heating terephthalic nitrile with alcoholic ammonium sulphide (Luckenbach, *B.* 17, 1430). Yellow amorphous powder, insol. alcohol. Boiling with lead acetate reproduces the nitrile.

THIOSULPHATES. Salts of the hypothetical *thiosulphuric acid* $\text{H}_2\text{S}_2\text{O}_4$. These salts were called *hyposulphites* before the isolation of the true hyposulphites ($\text{M}_2\text{S}_2\text{O}_4$, p. 592). $\text{Na}_2\text{S}_2\text{O}_4$ 5aq is still, however, commonly known as sodium hyposulphite. Thiosulphates are formed by boiling normal alkali sulphites in solution with S; ($\text{M}_2\text{SO}_3\text{Aq} + \text{S} = \text{M}_2\text{S}_2\text{O}_4\text{Aq}$); caustic alkali solutions and milk of lime also give thiosulphates by boiling with S. Thiosulphates are produced by the action of air, SO_2 , or $\text{K}_2\text{Cr}_2\text{O}_7\text{Aq}$ on the alkali and alkaline earth polysulphides in solution ($\text{M}_2\text{S}_x\text{Aq} + 3\text{O} = \text{M}_2\text{S}_2\text{O}_4\text{Aq} + 3\text{S}$; $2\text{M}_2\text{S}_x\text{Aq} + 3\text{SO}_2\text{Aq} = 2\text{M}_2\text{S}_2\text{O}_4\text{Aq} + 9\text{S}$; $2\text{M}_2\text{S}_x\text{Aq} + 4\text{M}_2\text{Cr}_2\text{O}_7\text{Aq} + \text{H}_2\text{O} = 5\text{M}_2\text{S}_2\text{O}_4\text{Aq} + 4\text{Cr}_2\text{O}_3 + 2\text{MOHAq}$ (Döpping, *A.* 46, 172). Spring (*B.* 7, 1157) by heating $(\text{NH}_4)_2\text{SO}_3$ with P_2S_5 got a large quantity of $(\text{NH}_4)_2\text{S}_2\text{O}_4$, along with $(\text{NH}_4)_2\text{S}_2$, and also some $(\text{NH}_4)_2\text{S}_2\text{O}_8$, and P compounds; and by the interaction of H_2S and $\text{SO}_2\text{NH}_2\text{ONH}_2$ he obtained $(\text{NH}_4)_2\text{S}_2\text{O}_4$. A little $\text{H}_2\text{S}_2\text{O}_4\text{Aq}$ is said to be formed by the interaction of steam and molten S (Myers, *A.* 129, 351).

The alkali salts, also the Ca and Sr salts, are readily soluble in water; many of the others are insoluble or only slightly soluble; the insoluble salts are often obtained from solutions of the alkali salts by double decomposition. Thiosulphates are decomposed by heating strongly; alkali salts leave a mixture of sulphate and sulphide; other salts also give off H_2S and S. Aqueous solutions of thiosulphates evolve H_2S when boiled, forming sulphates, or sulphides if the metal of the thiosulphate is ppd. by H_2S .

Aqueous solutions of thiosulphates are decomposed by dilute mineral acids, with separation of S and evolution of SO_2 . Salts of the acid used are formed, and $\text{H}_2\text{S}_2\text{O}_4\text{Aq}$, which then decomposes to $\text{H}_2\text{SO}_4\text{Aq}$ and S. This reaction has been studied by several chemists (*v. Berthelot*, *C. R.* 108, 971; Vaubel, *B.* 22, 1686, 2703; Vortmann, *B.* 22, 2307; Fousereau, *C. R.* 104, 1842). Colefax (*C. J.* 61, 176) in 1892 examined the interaction of $\text{Na}_2\text{S}_2\text{O}_4\text{Aq}$ and acids; he found that when the products of the change are not removed the interaction stops before all the

$\text{H}_2\text{S}_2\text{O}_4\text{Aq}$ is decomposed. C. determined the effects on the velocity and the limit of the reaction of concentration, increasing the relative mass of the acid used, the nature of the acid, temperature, and the presence of SO_2 in the solution before acidification (reference to older memoirs are given by C.).

Thiosulphates are converted into tetrathionates by the action of I; oxidisers such as HNO_3 , KClO_3 , and HClAq , and KMnO_4Aq produce sulphates. According to Hönig & Zatzek (*M.* 4, 738), KMnO_4 in solution in acetic acid produces dithionates.

For the general qualitative reactions of thiosulphates compared with those of thionates *v. Debus* (*C. J.* 53, 298).

SELENOTHIOSULPHATES M_2SeSO_3 are described as *Thioselenates*, under SELENATES (p. 434).

Constitution of thiosulphates. The formula $\text{SO}_2\text{OM.SM}$ is generally adopted for the normal thiosulphates of monovalent metals (Odling, *C. N.* 29, 153; cf. Schorlemmer, *C. J.* [2] 7, 254; Williamson, *C. J.* [2] 7, 259). Some chemists, considering the resemblances between thiosulphates and sulphites, have suggested the

formula SO^{OM} (*v. Blomstrand*, *Die Chemie*

der Jetztzeit [Heidelberg, 1869], 258; Buchanan, *B.* 3, 485; Michaelis, *G. O.* [5th ed.] 1, 745). The formation of thiosulphates by boiling sulphites with S is readily represented by either formula, according as sulphites are regarded as $\text{SO}_2\text{OM.M}$ or SO.O.M.O.M . As the balance of evidence is in favour of the formula $\text{SO}_2\text{OM.M}$, it is likely that the salts formed by adding S to the sulphites are $\text{SO}_2\text{OM.SM}$. The production of $(\text{NH}_4)_2\text{S}_2\text{O}_4$ by the interaction of $(\text{NH}_4)_2\text{SO}_3$ and P_2S_5 (Spring, *B.* 7, 1158) also confirms the formula $\text{SO}_2\text{OM.SM}$, inasmuch as a thiosulphate is produced in this reaction from a sulphate ($\text{SO}_2\text{ONH}_2\text{ONH}_2$ giving $\text{SO}_2\text{ONH}_2\text{SNH}_2$). Spring's synthesis of $\text{H}_2\text{S}_2\text{O}_4$ from SO_2 and H_2S —for the actual reaction carried out, viz. formation of $(\text{NH}_4)_2\text{S}_2\text{O}_4$ by first combining SO_2 and NH_3 , and then interacting with H_2S , is equivalent to the synthesis of $\text{H}_2\text{S}_2\text{O}_4$ (*v. S.*, *l.c.*)—is also in keeping with the formula $\text{SO}_2\text{OM.SM}$. By warming EtBr with $\text{Na}_2\text{S}_2\text{O}_4\text{Aq}$, Bunte (*B.* 7, 646) obtained the salt EtNaS_2O_4 . This salt is decomposed by dilute acids giving EtSH and $\text{SO}_2\text{OH.ONa}$; when heated it gives off Et_2S_2 and SO_2 , leaving Na_2SO_4 . These reactions indicate that EtNaS_2O_4 is $\text{SO}_2\text{Na.EtS}$; hence the formula of $\text{Na}_2\text{S}_2\text{O}_4$ is probably $\text{SO}_2\text{Na.NaS}$. One of the Na atoms in $\text{Na}_2\text{S}_2\text{O}_4$ is then probably in direct union with an atom of S; and as EtNaS_2O_4 easily gives $\text{SO}_2\text{OH.ONa}$, along with EtSH , it is likely that the formula of this salt is $\text{SO}_2\text{ONa.SEt}$, and hence that the formula for $\text{Na}_2\text{S}_2\text{O}_4$ is $\text{SO}_2\text{ONa.SNa}$. The formula $\text{SO}_2\text{OH.SH}$ makes possible the existence of two isomeric salts $\text{MM'S}_2\text{O}_4$, viz. $\text{SO}_2\text{OM.SM'}$ and $\text{SO}_2\text{OM'.SM}$; two such salts are known where $\text{M} = \text{Na}$ and $\text{M}' = \text{K}$. (*v. POTASSIUM THIOSULPHATE*, p. 706).

Ammonium thiosulphate $(\text{NH}_4)_2\text{S}_2\text{O}_4$. Obtained by the interaction of $(\text{NH}_4)_2\text{CO}_3$ and $\text{CaS}_2\text{O}_4\text{Aq}$, filtering and evaporating (Rammelsberg, *P.* 56, 298); white, rhombic, deliquescent leaflets, crystallising with $x\text{H}_2\text{O}$. Fock & Kläss (*B.* 22, 3099; 23, 534) obtained the anhydrous Z Z

salt by reacting on SO_2Aq with $(\text{NH}_4)_2\text{S}_8$, evaporating at a low temperature and finally over H_2SO_4 , and thoroughly drying between filter paper (cf. Arppe, *A.* 96, 118). The anhydrous salt is not deliquescent (F. a. K.). *Double salts* are described by F. a. K. (*l.c.*); also B. 23, 1758: (1) with CdS_2O_8 ; (2) with MgS_2O_8 ; (3) with $\text{K}_2\text{S}_2\text{O}_8$, the salt obtained was $\text{SO}_2\cdot\text{OK}\cdot\text{SNH}_4$. F. a. K. could not obtain $\text{SO}_2\cdot\text{ONH}_4\cdot\text{SK}$; (4) with $\text{Cu}_2\text{S}_2\text{O}_8$ and Cu_2I_2 , also with Cu_2I_2 and NH_4I (Brun, *C. R.* 114, 667); (5) with PbS_2O_8 (Rammelsberg, *P.* 56, 808); (6) with HgS_2O_8 (R., *l.c.*).

Barium thiosulphate $\text{BaS}_2\text{O}_8\cdot\text{aq}$. A white pp. obtained by mixing $\text{Ba}(\text{C}_2\text{H}_3\text{O}_2)_2\text{Aq}$ and $\text{Na}_2\text{S}_2\text{O}_8\text{Aq}$, and completing ppn. by alcohol; loses all water at 170° ; at red heat gives BaS , BaSO_4 , BaSO_3 , and S (H. Rose, *P.* 21, 437; Rammelsberg, *P.* 56, 295).

Double salts. (1) With CdS_2O_8 (Fock a. Klüss, *B.* 23, 1758); (2) with $\text{Cu}_2\text{S}_2\text{O}_8$ (Cohen, *C. J.* 51, 38); (3) with PbS_2O_8 (Rammelsberg, *P.* 56, 808).

Cadmium thiosulphate $\text{CdS}_2\text{O}_8\cdot 2\text{aq}$ (F. a. K., *B.* 23, 534); *double salts* with (1) $\text{Na}_2\text{S}_2\text{O}_8$, (2) $\text{K}_2\text{S}_2\text{O}_8$, (3) SrS_2O_8 (F. a. K., *B.* 23, 1758; Vortmann a. Padberg, *B.* 22, 2637).

Calcium thiosulphate $\text{CaS}_2\text{O}_8\cdot 6\text{aq}$. Formed by mixing hot conc. solutions of CaCl_2 and $\text{Na}_2\text{S}_2\text{O}_8$, evaporating under 60° , separating NaCl , which crystallises first, and allowing to cool (Kessler, *P.* 74, 282). Also obtained by heating CaSO_4 and S with water, or by boiling milk of lime with S, passing in SO_2 , and crystallising below 60° (Herschel, *N. Ed. P. J.* 1, 8, 296; 2, 154). Forms large, clear, six-sided, triclinic prisms, that effloresce in air at 40° ; S. 100 at 3° (H., *l.c.*). Conc. solution gives CaSO_4 and S by heating above 60° . Rammelsberg (*P.* 56, 808) describes a *double salt* with PbS_2O_8 .

Cobalt thiosulphate $\text{CoS}_2\text{O}_8\cdot 6\text{aq}$ (Rammelsberg, *P.* 56, 398; Fock a. Klüss, *B.* 22, 3810). A *double salt* with $\text{Na}_2\text{S}_2\text{O}_8$ is described by Vortmann a. Padberg (*B.* 22, 2637).

Copper thiosulphates. According to von Hauer (*W. A. B.* 13, 448) an *acid cuprous salt* $\text{Cu}_2\text{H}(\text{S}_2\text{O}_8)_2$, is obtained, in microscopic, golden-yellow needles, by adding conc. CuSO_4Aq to $\text{Na}_2\text{S}_2\text{O}_8\text{Aq}$ till the liquid is deep yellow, and gently warming, washing the pp. with water and alcohol, and drying over H_2SO_4 . *Double salts* of $\text{Cu}_2\text{S}_2\text{O}_8$: (1) with BaS_2O_8 (Cohen, *C. J.* 51, 38); (2) with $\text{K}_2\text{S}_2\text{O}_8$ (C., *l.c.*; Rammelsberg, *P.* 56, 821); (3) with $\text{Ag}_2\text{S}_2\text{O}_8$ (C., *l.c.*); (4) with $\text{Na}_2\text{S}_2\text{O}_8$ (Lenz, *A.* 40, 99; Siewert, *J.* 1866, 267; Kessel, *B.* 10, 1677, 2000; Schütte, *J. pr.* 70, 249; Vortmann, *M.* 9, 165).

Iron thiosulphate. The *ferrous salt* $\text{FeS}_2\text{O}_8\cdot 6\text{aq}$ was obtained by Vortmann a. Padberg (*B.* 22, 2637) by rubbing BaS_2O_8 with conc. FeSO_4Aq (the salts being present in the ratio of equal numbers of molecules), filtering from BaSO_4 , adding a mixture of alcohol and ether, and allowing the green, oily liquid that separated to stand for some days. Small green crystals; very sol. water; solution is decomposed by boiling, with separation of FeS . A *double salt* with $\text{Na}_2\text{S}_2\text{O}_8$ is described by V. a. P. (*l.c.*). For accounts of former attempts to prepare pure ferrous thiosulphate v. Fordos a. Gélis (*J. Ph.* [3] 4, 888); Berthelot (*A. Ch.*

[5] 2, 58); Vogel (*J. pr.* 8, 102); Koene (*P.* 63, 245, 431); Rammelsberg (*P.* 56, 806).

No *ferric thiosulphate* has been isolated.

Lead thiosulphate PbS_2O_8 . Obtained by adding $\text{Na}_2\text{S}_2\text{O}_8\text{Aq}$ to $\text{Pb}(\text{NO}_3)_2\text{Aq}$, or $\text{Pb}(\text{C}_2\text{H}_3\text{O}_2)_2\text{Aq}$, and washing the pp. with cold water. A white solid; very sol. water; sol. solutions of alkali thiosulphates (v. Pape, *J.* 1864, 57; Letts, *O. J.* [2] 8, 424). For reaction with POCl_3 —giving PbOCl , HCl , SO_2 , SOCl_2 , POCl_3 , and probably PSOCl —v. Buchanan (*B.* 3, 485). Rammelsberg (*P.* 56, 808) has described *double salts* with the thiosulphates of NH_4 , Ba , Ca , K (v. also Spring, *B.* 7, 1157), and Na (v. also Vortmann a. Padberg, *B.* 22, 2637).

Lithium thiosulphate $\text{Li}_2\text{S}_2\text{O}_8\cdot 8\text{aq}$ (v. Fock a. Klüss, *B.* 22, 3096).

Magnesium thiosulphate $\text{MgS}_2\text{O}_8\cdot 6\text{aq}$. By passing SO_2 into MgSAq till colourless, boiling MgSO_4 in SO_2Aq with S, or adding $\text{BaS}_2\text{O}_8\text{Aq}$ to MgSO_4Aq and filtering, a solution is obtained which on evaporation at a low temperature gives small, white, prismatic crystals of this salt. Loses $3\text{H}_2\text{O}$ at 170° , and gives off SO_2 and S at red heat, leaving MgSO_4 and MgO (Herschel, *N. Ed. P. J.* 1, 8, 296; 2, 154; Rammelsberg, *P.* 56, 308; Fock a. Klüss, *B.* 22, 3810). *Double salts* (1) with $(\text{NH}_4)_2\text{S}_2\text{O}_8$, (2) with $\text{K}_2\text{S}_2\text{O}_8$, are described by R. (*l.c.*); v. also Kessler, *P.* 74, 256; also F. a. K., *B.* 23, 534).

Manganese thiosulphate $\text{MnS}_2\text{O}_8\cdot 5\text{aq}$. Formed similarly to $\text{FeS}_2\text{O}_8\cdot 5\text{aq}$ (Vortmann a. Padberg, *B.* 22, 2637). A *double salt* with $\text{Na}_2\text{S}_2\text{O}_8$ is described by V. a. P. (*l.c.*).

Mercury thiosulphates. Neither the mercurous nor the mercuric salt has been isolated. Addition of a thiosulphate to solution of a mercurous salt ppts. Hg_2S ; with a mercuric salt, a compound of HgS with the mercuric salt employed is said to be formed (Rammelsberg, *P.* 56, 314). *Double salts of mercurous thiosulphate* with (1) $(\text{NH}_4)_2\text{S}_2\text{O}_8$, (2) $\text{Cu}_2\text{S}_2\text{O}_8$, (3) $\text{Na}_2\text{S}_2\text{O}_8$, are described by Rammelsberg (*l.c.*); and a *double salt of mercuric thiosulphate* with $\text{K}_2\text{S}_2\text{O}_8$ by Vortmann a. Padberg (*B.* 24, 1851).

Nickel thiosulphate $\text{NiS}_2\text{O}_8\cdot 6\text{aq}$ (Rammelsberg, *P.* 56, 309; Fock a. Klüss, *B.* 22, 3310). For a *double salt* with $\text{Na}_2\text{S}_2\text{O}_8$ v. Vortmann a. Padberg (*B.* 22, 2637).

Platinum thiosulphate. Not isolated; but Schottländer (*A.* 140, 200) describes a *double salt* $\text{PtS}_2\text{O}_8\cdot 3\text{Na}_2\text{S}_2\text{O}_8\cdot 10\text{aq}$.

Potassium thiosulphate $\text{K}_2\text{S}_2\text{O}_8$. Obtained by boiling conc. K_2SO_4 with excess of S; or by adding hot $\text{K}_2\text{Cr}_2\text{O}_7\text{Aq}$ to hot $\text{K}_2\text{S}_2\text{O}_8\text{Aq}$, little by little, waiting after each addition till the separated Cr_2O_3 is pure green in colour ($2\text{K}_2\text{S}_2\text{O}_8\text{Aq} + 4\text{K}_2\text{Cr}_2\text{O}_7\text{Aq} + \text{H}_2\text{O}$ = $5\text{K}_2\text{S}_2\text{O}_8\text{Aq} + 2\text{KOH}\cdot\text{Aq} + 4\text{Cr}_2\text{O}_3$); (Döpping, *A.* 46, 172; Kessler, *P.* 74, 274). In either case the filtered solution is evaporated to the crystallising point, and the crystals of $\text{K}_2\text{S}_2\text{O}_8\cdot x\text{H}_2\text{O}$ are heated to c. 180° . By evaporating at 80° , thin, four-sided, deliquescent prisms are obtained of the *hydrated salt* $3\text{K}_2\text{S}_2\text{O}_8\cdot \text{H}_2\text{O}$ (Rammelsberg, *P.* 56, 296; Kessler, *l.c.*; Fock a. Klüss, *B.* 22, 3096). This hydrate is very sol. water, but insol. alcohol; it loses all water at c. 180° ; heated more strongly it decomposes to K_2S_4 and K_2SO_4 (R., *l.c.*). Other hydrates are described by D. a. P., *l.c.* (v. also Plessy, *A. Ch.*

[3] 11, 182; F. a. K., *l.c.*). The final products of the action of SO_2 on $\text{K}_2\text{S}_2\text{O}_8\text{Aq}$ are $\text{K}_2\text{S}_2\text{O}_8\text{Aq}$, $\text{K}_2\text{S}_2\text{O}_8\text{Aq}$, and $\text{K}_2\text{S}_2\text{O}_8\text{Aq}$ (Debus, *C. J.* 53, 843).

Double salts.—(1) with $(\text{NH}_4)_2\text{S}_2\text{O}_8$ (Fock a. Klüss, *B.* 23, 534); the salt obtained was $\text{SO}_2\text{OK.SNH}_4$, the isomeric salt $\text{SO}_2\text{ONH}_4\text{SK}$ could not be isolated; (2) with $\text{Bi}_2(\text{S}_2\text{O}_8)_3$ (Carnot, *C. R.* 83, 838); (3) with CdS_2O_8 (F. a. K., *B.* 23, 534); (4) with $\text{Cu}_2\text{S}_2\text{O}_8$ (Cohen, *C. J.* 51, 88); (5) with HgCy_2 (F. a. K., *B.* 24, 1351); (6) with HgS_2O_8 (F. a. K., *l.c.*); (7) with PbS_2O_8 (Rammelsberg, *P.* 56, 308; Spring, *B.* 7, 1157); (8) with $\text{Ag}_2\text{S}_2\text{O}_8$ (Cohen, *C. J.* 51, 88; Schwicker, *B.* 22, 1728, describes $\text{KAgS}_2\text{O}_8\text{NH}_3$). (9) With $\text{Na}_2\text{S}_2\text{O}_8$, two salts are obtained: (i.) $\text{SO}_2\text{OK.NaS}_2\text{O}_8$, by the interaction of $\text{Am}_2\text{S}_2\text{O}_8\text{Aq}$ and $\text{NaKSO}_3\text{.2aq}$; (ii.) $\text{SO}_2\text{SK.ONa.2aq}$, by the interaction of $\text{Am}_2\text{S}_2\text{O}_8$ and KNaSO_3 (*v. SULPHATES*, p. 587); the first salt melts at c. 57° and has $S. = 218.7$ at 15° , heated with EtBr it gives $\text{SO}_2\text{OK.SET}$; the second salt melts at c. 62° and has $S. = 105.3$ at 15° , heated with EtBr it gives $\text{SO}_2\text{ONa.SET}$ (Schwicker, *B.* 22, 1728).

Silver thiosulphate $\text{Ag}_2\text{S}_2\text{O}_8$. This salt has probably not been isolated pure. On adding dilute AgNO_3Aq to $\text{K}_2\text{S}_2\text{O}_8\text{Aq}$ a white pp. is formed, and is dissolved on shaking; addition of more AgNO_3Aq produces a greyish, flocculent pp., which is a mixture of $\text{Ag}_2\text{S}_2\text{O}_8$ and Ag_2S . By treating this pp. with NH_4Aq , filtering from Ag_2S , exactly neutralising the filtrate by HNO_3Aq , and quickly drying the white flocculent pp. that formed between filter paper, Herschel (*N. Ed. P. J.* 1, 26, 398; 2, 154) obtained fairly pure $\text{Ag}_2\text{S}_2\text{O}_8$. A white powder; slightly soluble water; solution has a sweet taste; decomposes readily to Ag_2S and $\text{H}_2\text{SO}_4\text{Aq}$.

Double salts. Ag_2O and Ag salts generally dissolve readily in solutions of alkali thiosulphates, forming double salts, either of the form $2\text{AgMS}_2\text{O}_8\text{.aq}$, or of the form $\text{Ag}_2\text{M}_2(\text{S}_2\text{O}_8)_2\text{.2aq}$ (Herschel, *l.c.*). (1) With $(\text{NH}_4)_2\text{S}_2\text{O}_8$; by adding excess of AgCl to $(\text{NH}_4)_2\text{S}_2\text{O}_8\text{Aq}$, and washing the white crystalline pp., $2\text{Ag}(\text{NH}_4)_2\text{S}_2\text{O}_8\text{.aq}$ is obtained. Using less AgCl and ppg. the solution by alcohol produces $\text{Ag}_2(\text{NH}_4)_2(\text{S}_2\text{O}_8)_2\text{.2aq}$ (H., *l.c.*). (2) With $\text{Na}_2\text{S}_2\text{O}_8$; addition of AgNO_3Aq , drop by drop, with constant shaking, to $\text{Na}_2\text{S}_2\text{O}_8\text{Aq}$, till a permanent pp. begins to form, followed by addition of alcohol, ppts. $\text{Ag}_2\text{Na}_2(\text{S}_2\text{O}_8)_2\text{.2aq}$; the salt is washed with alcohol, and dried *in vacuo* (Lenz, *A.* 40, 94); when the mother-liquor from this salt is allowed to evaporate $2\text{AgNaS}_2\text{O}_8\text{.aq}$ is deposited (Herschel, *l.c.*; cf. Lenz, *l.c.*). The second of these salts is much less soluble in water than the first; it dissolves in $\text{Na}_2\text{S}_2\text{O}_8\text{Aq}$, with formation of $\text{Ag}_2\text{Na}_2(\text{S}_2\text{O}_8)_2\text{.2aq}$. Both salts are decomposed by boiling their aqueous solutions, with formation of Ag_2S . (3) With $\text{K}_2\text{S}_2\text{O}_8$; two salts are known similar to the sodium salts. Schwicker (*B.* 22, 1738) describes the compound $\text{AgKS}_2\text{O}_8\text{NH}_3$. Herschel (*l.c.*) obtained double salts with CaS_2O_8 and with SrS_2O_8 .

Sodium thiosulphate $\text{Na}_2\text{S}_2\text{O}_8\text{.5aq}$.

Formation.—1. By boiling $\text{Na}_2\text{SO}_3\text{Aq}$ with S .—2. By passing SO_2 into solution of sodium polysulphides.—3. By the action of SO_2 on *soda waste* suspended in water, whereby $\text{CaS}_2\text{O}_8\text{Aq}$ is formed; followed by addition of Na_2SO_3 , filtration from CaSO_4 , and evaporation.

Preparation.— $\text{Na}_2\text{SO}_3\text{.2aq}$ is dissolved in a little water, the solution is boiled with flowers of sulphur for a considerable time, and filtered; the clear, colourless liquid is evaporated to the crystallising point, and the crystals that separate are purified by recrystallisation from water.

Properties.—Large, white, monoclinic prisms; *S.G.* 1.736 at 10° (Kopp, *J.* 8, 45; cf. Schiff, *J.* 12, 41; Smith, *Am. J. Pharm.* 58, 148). Melts at 45° in the water of crystallisation (Kopp, *J.* 8, 45); at 48.5° (Tilden, *C. J.* 45, 268). The crystals are dehydrated by keeping *in vacuo* over H_2SO_4 , or by heating to 100° . *S.* 49.75 at 0° , 69.44 at 20° , 104.16 at 40° , 192.8 at 60° (Kremers, *P.* 99, 50). An aqueous solution of the salt is easily supersaturated; thus Schiff (*A.* 113, 350) dissolved 171 parts $\text{Na}_2\text{S}_2\text{O}_8\text{.5aq}$ (=108.9 parts $\text{Na}_2\text{S}_2\text{O}_8$) in 100 parts water at 19.1° , and Kremers obtained a solution of 217.4 parts $\text{Na}_2\text{S}_2\text{O}_8$ in 100 parts water at the ordinary temperature. According to Baumhauer (*J. pr.* 104, 148), a supersaturated solution may be cooled to -10° without crystallising; addition of a crystal of the salt causes rapid crystallisation, with the evolution of much heat (cf. Parmentier a. Amat, *C. R.* 98, 735). Solution of $\text{Na}_2\text{S}_2\text{O}_8\text{.5aq}$ in water is accompanied by the disappearance of much heat; Rüdorff (*B.* 2, 68) says that 110 parts $\text{Na}_2\text{S}_2\text{O}_8\text{.5aq}$ dissolving in 100 parts water lower the temperature from 10.7° to -8° , *i.e.* through 18.7° . Schiff (*A.* 113, 350) gives the following data for *S.G.* and composition of aqueous solutions of $\text{Na}_2\text{S}_2\text{O}_8\text{.5aq}$:—

<i>S.G.</i> of sol.	<i>P.p.</i> $\text{Na}_2\text{S}_2\text{O}_8\text{.5aq}$	<i>P.p.</i> $\text{Na}_2\text{S}_2\text{O}_8$	<i>S.G.</i> of sol.	<i>P.p.</i> $\text{Na}_2\text{S}_2\text{O}_8\text{.5aq}$	<i>P.p.</i> $\text{Na}_2\text{S}_2\text{O}_8$

$\text{Na}_2\text{S}_2\text{O}_8\text{.5aq}$ is insol. alcohol.

According to Jochem (*C. O.* 1885, 642), a *trihydrated salt* $\text{Na}_2\text{S}_2\text{O}_8\text{.3aq}$ is obtained by adding alcohol to a saturated solution of the ordinary salt, removing the oily liquid that separates, and adding to it 98 p.c. alcohol. According to Parmentier a. Amat (*C. R.* 98, 735), $\text{Na}_2\text{S}_2\text{O}_8\text{.5aq}$ is obtained crystallised in needles, melting at c. 32° , by placing a supersaturated

solution of the ordinary salt in a freezing mixture in a closed vessel.

Reactions.—1. Heat decomposes $\text{Na}_2\text{S}_2\text{O}_3$; the change begins at c. 220° with separation of S, at c. 400° Na_2SO_3 and Na_2S_3 are formed, and at a higher temperature more S is given off, and Na_2SO_3 and Na_2S_3 remain.—2. $\text{Na}_2\text{S}_2\text{O}_3\text{Aq}$ interacts with iodine in KIAq to form NaIAq and $\text{Na}_2\text{S}_4\text{O}_6\text{Aq}$; according to Villiers (*C. R.* 108, 402) some $\text{Na}_2\text{S}_2\text{O}_8$ is also formed. With a mixture of Na_2SO_3 and $\text{Na}_2\text{S}_2\text{O}_3$ in solution I produces NaIAq , $\text{Na}_2\text{SO}_4\text{Aq}$ and $\text{Na}_2\text{S}_4\text{O}_6\text{Aq}$ (Colefax, *C. J.* 61, 198, 1083).—3. $\text{Na}_2\text{S}_2\text{O}_3$ is oxidised by potassium permanganate solution; in alkaline solutions the oxidation is complete to $\text{Na}_2\text{SO}_4\text{Aq}$ according to Hönig a. Zatzek (*M.* 4, 788); Glaser (*M.* 6, 329) says that the oxidation is also complete in neutral solutions; Luckow (*Fr.* 32, 53) represents the oxidation, on boiling, either in neutral, acid, or alkaline solution as producing Na_2SO_4 and $\text{Na}_2\text{S}_4\text{O}_6$.—4. Acids interact with $\text{Na}_2\text{S}_2\text{O}_3\text{Aq}$, forming Na salts of the acids, and $\text{H}_2\text{S}_2\text{O}_3\text{Aq}$ which then decomposes to $\text{H}_2\text{SO}_3\text{Aq}$ and S; when the products are not removed from the solution the reaction stops before all the $\text{H}_2\text{S}_2\text{O}_3$ is decomposed (Colefax, *C. J.* 61, 176; and v. beginning of article THIOSULPHATES, p. 705).

Combinations.—1. With water (v. *supra*, Properties).—2. With various thiosulphates to form double salts. Double salts with CdS_2O_3 , CoS_2O_3 , FeS_2O_3 , PbS_2O_3 , MnS_2O_3 , NiS_2O_3 , TiS_2O_3 , and ZnS_2O_3 are described by Vortmann a. Padberg (*B.* 22, 2637); Fock a. Klüss (*B.* 23, 1753) also describe that with CdS_2O_3 . Rammelsberg (*P.* 56, 308) prepared salts with PbS_2O_3 and $\text{Hg}_2\text{S}_2\text{O}_3$. For a double salt with $\text{Hg}_2\text{S}_2\text{O}_3$ v. Schwicker (*B.* 22, 1728). For the double salts with $\text{K}_2\text{S}_2\text{O}_3$ v. POTASSIUM THIOSULPHATE, double salts, No. (9) (p. 707), and for those with $\text{Ag}_2\text{S}_2\text{O}_3$ v. SILVER THIOSULPHATE, double salts, No. (2) (p. 707). Schottländer (*A.* 140, 200) describes a double salt $3\text{Na}_2\text{S}_2\text{O}_3 \cdot \text{PtS}_2\text{O}_3 \cdot 10\text{aq}$.

Strontium thiosulphate $\text{SrS}_2\text{O}_3 \cdot 5\text{aq}$. Prepared like the Ba salt (Herschel, *N. Ed. P. J.* 1, 26, 398; 2, 154; Kessler, *P.* 74, 274). Fock a. Klüss (*B.* 22, 3310) describe a salt $\text{SrS}_2\text{O}_3 \cdot \text{aq}$.

Thallium thiosulphate TlS_2O_3 . A white, crystalline pp., formed by adding $\text{Na}_2\text{S}_2\text{O}_3\text{Aq}$ to fairly conc. TlOHAq (Crookes, *C. J.* 17, 136; Hebbeling, *A.* 134, 11). For a double salt with $\text{Na}_2\text{S}_2\text{O}_3$ v. Werther (*J. pr.* 92, 130); Vortmann a. Padberg (*B.* 22, 2637); also Jochum (*C. C.* 1885, 642).

Zinc thiosulphate ZnS_2O_3 . Prepared by double decomposition from ZnSO_4Aq and $\text{BaS}_2\text{O}_3\text{Aq}$ (v. Rammelsberg, *P.* 56, 295; Fordos a. Gélis, *J. pr.* 29, 291). For a compound with NH_3 v. R. (*l.c.*). For a double salt with $\text{Na}_2\text{S}_2\text{O}_3$ v. Vortmann a. Padberg (*B.* 22, 2637).

M. M. P. M.

THIOSULPHURIC ACID $\text{H}_2\text{S}_2\text{O}_3\text{Aq}$. This acid almost certainly exists in the liquid obtained by adding a dilute weak acid to dilute $\text{Na}_2\text{S}_2\text{O}_3\text{Aq}$, the acid and salt being mixed in equivalent quantities; the $\text{H}_2\text{S}_2\text{O}_3\text{Aq}$ soon begins to decompose to $\text{H}_2\text{SO}_3\text{Aq}$ and S. Landolt (*B.* 16, 2958) has made an extensive investigation into the conditions and time of existence of $\text{H}_2\text{S}_2\text{O}_3$ in solution. Thomsen (*Th.* 2, 256) gives the thermal data; $[\text{SO}^-\text{Aq.S}] = -9810$; $[\text{SO}^-\text{S.Aq}] = -1610$.

For the salts of $\text{H}_2\text{S}_2\text{O}_3$ v. THIOSULPHATES.

M. M. P. M.

THIOTOLENE v. Methylthiophene.

THIO-o-TOLUIC ACID. *Amide* $\text{C}_6\text{H}_4\text{Me.CS.NH}_2$. [88°]. Formed from o-toluic nitrile (Gabriel a. Heymann, *B.* 24, 786).

Thio-p-toluic acid. *Amide*. [168°]. Formed by passing H_2S into an alcoholic solution of p-toluic nitrile (Paterno a. Spica, *B.* 8, 441). Yellowish needles. Zinc and HClAq yield $\text{C}_6\text{H}_4\text{Me.CH}_2\text{NH}_2$.

THIO-TOLUIDINE v. DI-AMIDO-DI-TOLYL SULPHIDE.

THIO-p-TOLYL-DI-PHENYL-DI-GUANIDINES v. DI-PHENYL-DI-GUANIDO-DI-TOLYL SULPHIDE and DI-PHENYL-DI-CARBIMIDO-TETRA-AMIDO-TETRA-TOLYL DISULPHIDE.

THIO-TOLYL-DI-PHENYL-THIO-UREA v. DI-PHENYL-DI-THIOURAMIDO-DI-TOLYL SULPHIDE.

THIO-URAMIDO-BARBITURIC ACID

$\text{C}_6\text{H}_4\text{N}_2\text{SO}_2$ i.e. $\text{NH}_2\text{C}(\text{NH})\text{S.CH} \begin{smallmatrix} \text{CO.NH} \\ \text{CO.NH} \end{smallmatrix} \text{CO}$.

Formed by the action of thio-urea on an aqueous solution of chloro-, bromo-, or di-bromo-barbituric acid (Mulder, *B.* 12, 2309; Trzcinski, *B.* 16, 1057). Formed also by heating alloxan with thio-urea and alcoholic SO_2 at 100° (Nencki, *B.* 4, 722; 5, 451). Slender needles, insol. water, sol. hot HClAq . Converted by boiling KOHAc into thio-dialuric acid $\text{C}_6\text{H}_4\text{N}_2\text{SO}_2$, $1\frac{1}{2}\text{aq}$ (?) which yields KA^-aq . H_2SO_4 ($\frac{1}{2}$ pt.) at 150° – 160° forms uro-sulphonic acid $\text{C}_6\text{H}_4\text{N}_2\text{SO}_2$.

THIO-URAMIDO-BENZENE p-SULPHONIC ACID. The salt $\text{NH}_2\text{CS.NH.C}_6\text{H}_4\text{SO}_3\text{K}$, formed by heating potassium sulphocyanide with amido-benzene p-sulphonic acid at 140° , crystallises from dilute alcohol in aggregates of thin needles (Pellizzari, *A.* 248, 156).

m-THIO-URAMIDO-BENZOIC ACID

$\text{NH}_2\text{CS.NH.C}_6\text{H}_4\text{CO}_2\text{H}$. [187°]. Formed from m-amido-benzoic acid and potassium sulphocyanide (Arzruni, *B.* 4, 406). Formed also by allowing a solution of m-cyanamido-benzoic acid in colourless ammonium sulphide to stand for 24 hours (Traube, *B.* 15, 2118). Needles. Converted by ammoniacal AgNO_3 into m-uramido-benzoic acid. Not coloured by FeCl_3 .

p-THIO-URAMIDO-BENZYL-THIO-UREA

$\text{NH}_2\text{CS.NH.C}_6\text{H}_4\text{CH}_2\text{NH.CS.NH}_2$. *p-di-thio-uramido-toluene*. [176°]. Formed by heating p-amido-benzyl-amine hydrochloride (1 mol.) with potassium sulphocyanide (2 mols.) in aqueous solution (Amsel a. Hofmann, *B.* 19, 1289). White needles.

THIO-URAMIDO-BUTYRIC ACID. *Anhydride* $\text{NH}_2\text{C} \begin{smallmatrix} \text{S-CHEt} \\ \text{NH.CO} \end{smallmatrix}$. [200°]. Formed

from α -bromo-n-butyric acid and thio-urea (Andreasch, *M.* 8, 419). Needles, v. sol. hot water.

Thio-uramido-iso-butyric acid. *Anhydride*

$\text{C}_6\text{H}_4\text{N}_2\text{SO}$ i.e. $\text{NH}_2\text{C} \begin{smallmatrix} \text{S-QMe} \\ \text{NH.CO} \end{smallmatrix}$. [242°].

Formed from bromo-isobutyric acid and thio-urea (Andreasch, *M.* 8, 410). Plates, al. sol. water. Oxidised by HCl and KClO_3 to urea and α -sulpho-iso-butyric acid.

o-THIO-URAMIDO-CINNAMIC ACID

$\text{NH}_2\text{CS.NH.C}_6\text{H}_4\text{CH=CH.CO}_2\text{H}$. [236° – 239°]. Got by heating the sulphocyanide of o-amido-cinnamic acid $\text{C}_6\text{H}_4(\text{NH}_2\text{HSCy})\text{CH=CH.CO}_2\text{H}$

[152°] at 115° (Rothschild, *B.* 23, 8342). *V.* sol. hot HOAc and NH_4Aq .

a-Thio- ψ -uramido-cinnamic acid $\text{C}_{16}\text{H}_{19}\text{N}_2\text{SO}_2$, i.e. $\text{NH}:\text{C}(\text{NH}_2):\text{S}:\text{C}(\text{CO}_2\text{H}):\text{CHPh}$. Formed from benzoic aldehyde, thiohydantoin, and NaOHAq (Andreasch, *M.* 8, 421). Needles (from alcohol), decomposed by alkalis.

β -Thio- ψ -URAMIDO-PROPIONIC ACID $\text{NH}:\text{C}(\text{NH}_2):\text{S}:\text{CH}_2\text{CH}_2\text{CO}_2\text{H}$. Formed by heating *β* -iodo-propionic acid with thio-urea and water and a little NaOH (Andreasch, *M.* 6, 831). Small pyramids (containing 2aq), sl. sol. cold water and cold alcohol. Decomposed by baryta into cyanamide and $\text{CH}_3(\text{SH})\text{CH}_2\text{CO}_2\text{H}$. KClO_3 and HCl yield *β* -sulpho-propionic acid.

op-DI-THIO-URAMIDO-TOLUENE *v.* THIO-URAMIDO-BENZYL-THIO-UREA.

DI-*p*-THIO-URAMIDO-DI-TOLYL-*o*-SULPHIDE [2:1:4] $\text{S}(\text{C}_6\text{H}_4\text{Me.NH.CS.NH}_2)_2$. Thio-*p*-tolyl-di-thiurea. [121°]. Formed by evaporating to dryness an aqueous solution of di-*p*-amido-di-tolyl sulphide, hydrochloride and ammonium sulphocyanide (Truhlar, *B.* 20, 669). White amorphous powder. Sol. alcohol and benzene, sl. sol. ether.

THIO-UREA CSN_2H_4 , i.e. $\text{CS}(\text{NH}_2)_2$ or $\text{HS}:\text{C}(\text{NH}_2):\text{NH}$. Mol. w. 76. [170°]. S. 9 in the cold (Volhard, *J. pr.* [2] 9, 13).

Formation.—1. By heating dry ammonium sulphocyanide for two hours at 170°, cooling to 100°, adding an equal weight of water at 80°, filtering, and allowing to crystallise (Emerson Reynolds, *C. J.* 22, 1; Claus, *A.* 179, 113; Smolka a. Friedreich, *M.* 10, 90).—2. By the action of tin and HCl , or of HI , on persulphocyanic acid $\text{C}_2\text{H}_3\text{N}_2\text{S}_3$ (Glutz, *A.* 154, 39).—3. By passing dry H_2S into an ethereal solution of cyanamide (Baumann, *B.* 6, 1375).—4. By allowing a solution of cyanamide, mixed with yellow ammonium sulphide, to stand for a day (Baumann, *B.* 8, 26).—5. From cyanamide and thioacetic acid.—6. Together with urea by the action of ammonia on COS (Berthelot, *C. R.* 94, 1069).

Properties.—Silky trimetric needles, melting at 170°. After one fusion it melts at 149° (Prätorius, *J. pr.* [2] 21, 141). *V.* sol. water, nearly insol. alcohol and ether. Tastes bitter, not coloured by FeCl_3 . According to Armstrong (*C. J. Proc.* 8, 2), the molecule of thio-urea is $\text{C}_2\text{S}_2\text{N}_4\text{H}_6$.

Reactions.—1. Water at 140° forms ammonium sulphocyanide. Alcohol at 100° acts in like manner (Haller, *Bl.* [2] 45, 706).—2. An alcoholic solution of nitrous ether quickly converts it into ammonium sulphocyanide.—3. Prolonged heating at 170° also converts it into ammonium sulphocyanide. At 180° it slowly forms guanidine sulphocyanide and ammonium tri-thio-carbonate. Nitrous acid gives off nitrogen.—4. KOH at 100° slowly forms NH_3 , KSH , K_2CO_3 , and a little KCys . Alcoholic potash acts in like manner (Haller, *C. R.* 102, 974). H_2SO_4 and HCl act in the same way.—5. Aqueous KMnO_4 forms urea and other products (Maly, *M.* 11, 277).—6. Oxidising agents (e.g. H_2O_2 , $\text{K}_2\text{Cr}_2\text{O}_7$, KNO_3 , KMnO_4 , and iodine) form $\text{S}_2\text{C}(\text{NH}_2)_2(\text{NH})_2$, which has an insoluble nitrate (Storch, *M.* 11, 452).—7. Ammoniacal AgNO_3 forms urea and Ag_2S .—8. HgO , added to a cold aqueous solution, produces cyanamide.

PbO acts in like manner. At 100° the product is dicyandiamide (Hofmann, *B.* 2, 605).—

9. Acetoacetic ether reacts forming an ether $\text{C}_6\text{H}_5\text{N}_2\text{SO}(\text{OEt})$, which on saponification yields $\text{CS} \begin{smallmatrix} \text{NH.CMe} \\ \text{NH.CO} \end{smallmatrix} > \text{CH}$, *v.* sl. sol. water (Behrend, *B.* 19, 219).—10. $\text{CCl}_4.\text{COCl}$ forms $\text{C}_2\text{H}_4\text{Cl}_2\text{N}_2\text{S}_2\text{O}$, crystallising in slender needles, *m.* sol. alcohol, sl. sol. water, *v.* sl. sol. ether; converted by Br into $\text{CCl}_4.\text{SO}_2\text{Br}$ (McGowan, *C. J.* 49, 191; 51, 669; *J. pr.* [2] 36, 220). $\text{CCl}_4.\text{SO}_2\text{Cl}$ added to an alcoholic solution of thio-urea forms the chloride $\text{Cl}_2\text{CSN}_2\text{H}_4$, which is *ppd.* on adding ether, while the filtrate contains the compound $(\text{CSN}_2\text{H}_4)_2(\text{CCl}_4.\text{SO}_2)$ [125°], which is more sol. alcohol than water, and gives with Br a *pp.* of $\text{CCl}_4.\text{SO}_2\text{Br}$.—11. $\text{CCl}_4.\text{SO}_2\text{NH}_4$ in alcohol forms flat prisms of $(\text{CSN}_2\text{H}_4)_2\text{CCl}_4.\text{SO}_2\text{H}$ [139°], *m.* sol. water and ether, *v.* sol. alcohol, converted by Br into $\text{CCl}_4.\text{SO}_2\text{Br}$ (McGowan, *C. J.* 51, 667; *J. pr.* [2] 36, 219).—12. Chloro-acetone forms $(\text{NH}_2\text{CS.NH}.\text{CH}_2\text{CO}.\text{CH}_3)\text{HCl}$ [126°] (Pawlewski, *B.* 21, 402).—13. ClCO_2Et forms $(\text{NH}_2\text{CS.NH.CO}_2\text{Et})\text{HCl}$ [117°].—14. $\text{CH}_3\text{Cl}.\text{OH}$ gives $\text{C}_2\text{H}_4\text{N}_2\text{S}$, a white amorphous powder, insol. water, nearly insol. all usual menstrua, reconverted into thio-urea by HClAq (von Hemmelmayr, *M.* 12, 89).—15. Di-bromo-succinic acid forms fumaric acid on heating (Nencki a. Sieber, *J. pr.* [2] 25, 74).—16. A hot conc. solution of di-bromo-pyruvic acid forms 'sulphovinuric acid' $\text{C}_2\text{H}_4\text{N}_2\text{SO}_2$, which crystallises with 2aq, reduces Fehling solution to Cu_2O in the cold, and to a copper mirror on warming, and yields the salts CaA' , MgA' , ZnA' , $\text{HA}'\text{HCl}$, $\text{HA}'\text{HBr}$, and $\text{HA}'\text{HNO}_3\text{aq}$ (*N. a. S.*).—17. Bromo-pyruvic ether forms amido-thiazole carboxylic ether $\text{S} \begin{smallmatrix} \text{CH}=\text{CCO}_2\text{Et} \\ \text{C}(\text{NH}_2):\text{N} \end{smallmatrix}$ [173°] (Steude, *A.* 261, 30).—

18. Bromo-acetoacetic ether gives μ -amido-thiazyl-acetic ether $\text{S} \begin{smallmatrix} \text{CH}=\text{C}.\text{CH}_2.\text{CO}_2\text{Et} \\ \text{C}(\text{NH}_2):\text{N} \end{smallmatrix}$

[94°], which yields an acid [*c.* 130°], split up on fusion into CO_2 and amido-methyl-thiazole (Steude). *a*-Chloro-acetoacetic ether forms $\text{C}_6\text{H}_5\text{NSMe}(\text{NH}_2).\text{CO}_2\text{Et}$ [175°] (Zürcher, *A.* 250, 281).—19. Thio-urea heated with an alcoholic solution of chloro-acetic acid and phenyl-hydrazine forms $\text{C}_6\text{H}_5\text{N}_2\text{SO}$ [175°] (Probst, *J. pr.* [2] 45, 416).—20. Fusion with (*β*)-iodopropionic acid and a little water forms $\text{C}_6\text{H}_5\text{N}_2\text{SO}_2$ [176°], which crystallises from water in needles (containing 2aq), sl. sol. alcohol, insol. ether (Andreasch, *M.* 6, 832).—21. Di-chloro-acetic acid forms thiohydantoin. *α* -Bromo-propionic acid forms methyl-thiohydantoin (208° uncor.) (Dixon, *C. J.* 63, 815).—22. Aldehyde heated in a sealed tube with thio-urea forms $\text{CSN}_2\text{H}_2(\text{OHMe})$, which is sl. sol. ether and cold alcohol, and is decomposed by hot water (Reynolds, *C. N.* 24, 87).—23. Succinic anhydride at 140° forms $\text{C}_6\text{H}_5\text{N}_2\text{SO}_2$ [211°].—24. Citraconic anhydride at 130° forms $\text{C}_6\text{H}_5\text{N}_2\text{SO}_2$ [223°] (Pike, *B.* 6, 1104).—25. Acetyl-acetone and a small quantity of HClAq form $\text{CH}_2(\text{CMe}:\text{N}.\text{CS.NH}_2)\text{HCl}$ [219°]. In presence of excess of HCl the product is $\text{CH}_2 \begin{smallmatrix} \text{CMe}:\text{N} \\ \text{CMe}:\text{N} \end{smallmatrix} > \text{CS}$ [210°] (Evans, *J. pr.* [2] 48, 503).

Salts.— $\text{B}'\text{HNO}_3$. Crystalline. — $\text{B}'\text{HOL}$. Formed from the stannous double chloride and

H₂S. Crystalline.—B'HL. Tables.—B'NH₄Cl. [154°]. Felted crystalline mass (Reynolds, *C. J.* 59, 385).—B'NH₄I. [186°].—B'H₂PtCl₆. Yellow prisms, v. sol. water and alcohol. Can be dried at 100°.—B'H₂PtCl₆. Got when saturated solutions of thio-urea and PtCl₆ are mixed. Dark-red prisms, insol. water, alcohol and ether.—B'AuCl. Yellow monoclinic crystals, got by adding AuCl₃ to a saturated solution of thio-urea.—B'TiSO₄.—B'₂CuSO₄. White silky needles. Got by mixing conc. solutions of thio-urea and CuSO₄.—B'₂Cu₂(SO₄)₂ aq.—B'₂CuCl. Colourless dimetric crystals, sol. water, but ppd. by HCl and KCl. Alkaline in reaction. Attacked by H₂S with difficulty. Does not absorb CO (Rathke, *B.* 17, 801).—B'₂Cu₂Cl₂ aq. Ppd. by adding CuCl₂ aq. to aqueous thio-urea (Rathke, *B.* 14, 1779; 17, 301). Minute needles, insol. water.—B'₂CuCl. Flat needles. Formed by mixing the two preceding salts into which it is decomposed by water.—B'₄HgO.—B'₂(HgO)₂ 3aq. Ppd. by adding neutral Hg(NO₃)₂ to a dilute solution of thio-urea (Emerson Reynolds, *A.* 150, 235; Kurnakoff, *B.* 24, 3956). Crystalline. Loses thio-urea on washing with water.—B'₂HgCl₂: large crystals, v. sol. water.—B'₂HgCl₂: minute needles, nearly insol. water (Claus, *B.* 9, 227).—B'₂HgI₂ (Maly, *B.* 9, 173).—B'₂HgCyS. Needles, decomposed by heat into dicyandiamide, H₂Cy, and HgS (Nencki, *B.* 6, 598).—B'₂PbCl₂: needles (Claus, *A.* 179, 135).—B'₂Pb(CyS)₂.—B'₂SnCl₂.—B'₂ZnCl₂: spherical groups of prisms (from water).—B'₂CdSO₄.—B'₂SiBr₄ (Emerson Reynolds, *C. J.* 51, 202).—B'₂Ag₂O 4aq. Crystalline.—B'₂AgNO₃ (K.).—B'₂AgNO₃. [141°]. Silky crystals, sol. hot alcohol (Emerson Reynolds, *C. J.* 61, 249).—B'₂AgCl. [171°]. Needles, m. sol. hot alcohol.—B'₂AgBr. [121°].—B'₂AgI.—B'₂AgCy. [126°].—B'₂Ag₂C₂O₄: needles.

Chloride (CSN₂H₄)₂Cl₂. Formed by passing Cl into a conc. alcoholic solution of thio-urea (Claus, *A.* 179, 139). Formed also by the action of CCl₄, SO₂Cl, and of ICl, ICl₃, or POCl₃ on thio-urea (M'Gowan, *C. J.* 49, 191; *J. pr.* [2] 33, 188). Small needles, v. sol. water, m. sol. alcohol, insol. ether. Decomposed by alkalis, yielding cyanamide. Alcoholic KI removes chlorine, setting thio-urea free. Dilute HNO₃ forms crystals of (CSN₂H₄)₂(NO₃)₂, which is sl. sol. water, insol. alcohol and ether.

Bromide (CSN₂H₄)₂Br₂. Formed by adding Br to an alcoholic or cold aqueous solution of thio-urea; in aqueous solution excess of Br produces urea (Claus, *A.* 179, 138; M'Gowan, *C. J.* 51, 378; *J. pr.* [2] 36, 216). Crystals. Its aqueous solution deposits S when heated. Sodium amalgam reproduces thio-urea.

Iodide (CSN₂H₄)₂I₂. Formed from thio-urea, I, and alcohol (M'Gowan, *J. pr.* [2] 33, 192). Prisms.

Methylo-iodide (CSN₂H₄)MeI. [117°]. Formed slowly by combination of thio-urea with MeI in the cold (Bernthsen a. Klinger, *B.* 11, 493). Prisms, v. sol. water and alcohol. AgCl gives the chloride, which forms the platino-chloride (B'MeCl)₂PtCl₄ aq.

Ethylchloride B'EtCl. Crystals.

Ethylbromide (CSN₂H₄)EtBr. Hexagonal plates (Claus a. Siegfried, *A.* 179, 145). Decomposes at 100°.

Ethyl-iodide (CSN₂H₄)EtI. Crystal-

line. Gives with moist Ag₂O a base. Boiling aqueous alkalis liberate mercaptan.—B'₂Et₂PtCl₆ (dried at 100°). Tables.—B'₂EtI. Needles (from alcohol) (Claus, *B.* 8, 41).

Benzylchloride (CSN₂H₄)C₆H₅Cl. [168°]. Formed from benzyl chloride and thio-urea. Yields unstable benzyl-thio-urea CSN₂H₄C₆H₅ [72°], which decomposes at 100° into dicyandiamide and benzyl mercaptan (Bernthsen a. Klinger, *B.* 12, 574).—(CSN₂H₄C₆H₅)₂PtCl₄.

Compound with oxalic ether

(CSN₂H₄)₂Et₂C₂O₄. [150°]. Monoclinic crystals (Nencki, *B.* 7, 780). Decomposed by hot water.

Compounds with amines

(CSN₂H₄)₂NMeH₂Br. [138°]. Formed from methylamine hydrobromide and thio-urea in alcohol (Reynolds, *C. J.* 59, 392). Felted crystals.—(CSN₂H₄)₂NEt₂H₂Br. [134°]. Formed by boiling thio-urea together with diethylamine hydrobromide and absolute alcohol.—(CSN₂H₄)₂NEt₂HBr.—(CSN₂H₄)₂NEt₂I. [135°]. Prisms.—(CSN₂H₄)₂NEt₂Br [160°]. Rectangular prisms (Reynolds, *C. J.* 59, 388).

Acetyl derivative CSN₂H₄Ac. Mol. w.

118. [165°]. Formed by heating thio-urea with Ac₂O (Nencki, *B.* 6, 598). Formed also from thio-acetic acid and cyanamide (Frérotius, *J. pr.* [2] 21, 147). Prisms (from hot water), v. sol. alcohol, m. sol. ether.—B'H₂PtCl₆. Crystalline.

Propionyl derivative (Freitag, *J. pr.* [2] 20, 331).

Benzoyl derivative CSN₂H₄Bz. [170°].

Formed by warming thio-urea (2 mols.) with BzCl (1 mol.) (Pike, *B.* 6, 755). Got also from benzoyl sulphocyanide and NH₄Aq (Miguel, *Bl.* [2] 25, 252). Needles (from alcohol); sl. sol. cold water. Tastes bitter.

o-Oxy-benzoyl derivative

NH₂OS.NH.CO.C₆H₄.OH. [182°]. S. (boiling alcohol) 7. Formed from salicyl thiocarbimide and aqueous NH₃ (Miguel, *A. Ch.* [5] 11, 304).

THIO-ψ-URIC ACID v. THIO-URAMIDO-BARBITURIC ACID.

THIO-VALERIC ALDEHYDE C₄H₉S. (115°). Formed, together with C₂H₅S₂ [95°], by heating isovaleric aldehyde (23 pts.) with S (9 pts.) in sealed tubes at 250° for eight hours (Barbaglia, *G.* 11, 95; *B.* 17, 2654). Oil with penetrating odour like onions, sol. alcohol and ether. Does not combine with NaHSO₃.

Isomeride C₄H₉S. [69°]. V.D. (H=1) 50.76. Formed by passing H₂S into a dilute aqueous solution of isovaleric aldehyde. Fibrous crystals (from ether), insol. water.

THIOXENE v. DI-METHYL-THIOPHENE.

THIOXYLENOL v. XYLXL MERCAPTAN.

THIOXYL METHYL KETONE v. DI-METHYL-THIENYL METHYL KETONE.

THORIUM Th. (*Thorinum*). At. w. 232. Mol. w. unknown. The m.p. of Th has not been determined; it is certainly very high (Nilson, *B.* 15, 2541). S.G. 11.1 at 17° (N., *l.c.*, p. 2543). S.H. .02787 (N., *B.* 16, 161). Crystallises in regular octahedral and hexagonal forms, isomorphous with Si (Brügger, *Z. K.* 7, 442; cf. Nilson, *B.* 15, 2546; 16, 162 note). S.V.S. 20.9.

Historical.—In 1818 Berzelius announced the discovery of the oxide of a new element in a rare Norwegian mineral; to the metal of this oxide he gave the name thorium (from

the Scandinavian god *Thor*). A few years later Berzelius found that the substance he had supposed to be a new earth was really yttrium phosphate. In 1828, however, Berzelius isolated a new earth from another Norwegian mineral; he named the new earth thorite, and the mineral from which it had been prepared he called *thorite* (P. 16, 885). In 1851 Bergemann discovered a new metal and called it *donarium*; but this metal was shown to be identical with the thorium of Berzelius by Damour (C. R. 34, 685), Berlin (P. 87, 608), and Bergemann himself (P. 85, 558). In 1862 Bahr supposed he had found a new metal, which he called *wasium*, but soon afterwards he recognised that the metal was identical with thorium (P. 119, 572; 132, 227). The metal thorium was isolated by Berzelius in 1828 (P. 16, 885); it was also obtained by Chydenius in 1861 (*Bl.* [2] 1, 130); and in a state of greater purity by Nilson in 1882 (B. 15, 2537).

Occurrence.—Compounds of Th have been found only in very small quantities in a few localities. *Thorite* from Lövön in Norway contains c. 59 p.c. ThO_2 according to Berzelius; an orange-coloured variety of this mineral, *orangite*, was found by Bergemann to contain 74 p.c. ThO_2 ; Nilson (B. 15, 2519) found from 50 to 59 p.c. ThO_2 in different specimens of *thorite*. Small quantities of ThO_2 have been found in specimens of *pyrochlore*, *monazite*, *samaraskite*, *euxenite*, *gadolinite*, and *orthite*. Several minerals containing Th have been discovered by Hidden a. Mackintosh in North Carolina and Colorado; one of these is a silicophosphate of Th, another a silicate of Th and Y, another a silicate of Th and U, and another is a uranate of Th, Pb, and Y (*Am. S.* [3] 86, 461; 38, 474).

Formation.—1. By reducing ThCl_4 or $2\text{ThCl}_4 \cdot \text{KCl}$ by heating with K (Berzelius, P. 16, 885).—2. By reducing fused ThCl_4 or $2\text{ThCl}_4 \cdot \text{KCl}$ by means of Na (Chydenius, *Bl.* [2] 1, 130; 6, 438; Nilson, B. 15, 2537).

Preparation.—Powdered *thorite* is evaporated with HClAq to dryness; the residue is heated to render silica insoluble, and treated with water; the solution is filtered and ppd. by H_2S ; the filtrate from PbS is ppd. by NH_4Aq , and the pp. of crude $\text{ThO}_2 \cdot x\text{H}_2\text{O}$ is thoroughly washed and dissolved in HClAq ; $\text{Th}(\text{C}_2\text{O}_4)_2$ is ppd. from this solution by $\text{H}_2\text{C}_2\text{O}_4\text{Aq}$, and the pp., after being thoroughly washed with boiling water, is decomposed by heating; the crude ThO_2 thus obtained is converted into $\text{Th}(\text{SO}_4)_2$ by treatment in a Pt basin with conc. H_2SO_4 after being thoroughly moistened with water. The impure $\text{Th}(\text{SO}_4)_2$ thus obtained is freed from acid and water by heating, and is dissolved in as little ice-cold water as possible (c. 5 parts are required), and the solution is heated to c. 20° , when $\text{Th}(\text{SO}_4)_2 \cdot 9\text{H}_2\text{O}$ ppts. The $\text{Th}(\text{SO}_4)_2 \cdot 9\text{H}_2\text{O}$ is dehydrated by heating; the $\text{Th}(\text{SO}_4)_2$ is dissolved in the minimum quantity of ice-cold water and the solution is heated to c. 20° ; the crystals of $\text{Th}(\text{SO}_4)_2 \cdot 9\text{H}_2\text{O}$ that separate are dehydrated, dissolved in ice-cold water, and the hydrated sulphate is ppd. by heating to 20° . This treatment is repeated a few times, when pure $\text{Th}(\text{SO}_4)_2 \cdot 9\text{H}_2\text{O}$ is obtained. This method of purifying crude sulphate of Th, which is given by Nilson (B. 15, 2521), depends on the great differences between the solubilities in water of

$\text{Th}(\text{SO}_4)_2$ and $\text{Th}(\text{SO}_4)_2 \cdot 9\text{H}_2\text{O}$; the former, when pure, is soluble in 20.6 parts water at 0° , the latter requires 88 parts water at 0° , and much more at 20° , for solution. The sulphates of the metals present in the crude $\text{Th}(\text{SO}_4)_2$ prepared as described are much more soluble in water at 20° than $\text{Th}(\text{SO}_4)_2 \cdot 9\text{H}_2\text{O}$. For other methods of preparing salts of Th from *thorite* v. Berzelius (*l.c.*), Chydenius (*l.c.*), Delafontaine (*Ar. Sc.* [2] 18, 348), and Cleve (*Bl.* [2] 21, 115).

To prepare Th from pure $\text{Th}(\text{SO}_4)_2 \cdot 9\text{H}_2\text{O}$, Nilson (B. 15, 2538) dissolved the salt in water, ppd. by KOH Aq and boiled, washed the $\text{ThO}_2 \cdot x\text{H}_2\text{O}$ thoroughly, dissolved in HClAq and reppd. by KOH Aq (to remove all traces of H_2SO_4); he thoroughly washed the pp. by decantation, dissolved it in HClAq , added KCl , in the ratio $2\text{ThCl}_4 \cdot \text{KCl}$, evaporated to dryness in a Pt basin, and dried the residue by warming over a flame, stirring constantly, and then powdering and heating again. The dry double salt of ThCl_4 and KCl was heated to redness in a stream of dry HCl (prepared from conc. H_2SO_4 and sublimed NH_4Cl), HCl was removed by a stream of H , and some of the salt was transferred to a cylinder of wrought iron (fitted with a lid which screwed on), in which a layer of dry NaCl had been placed; pieces of sodium were arranged over the Th-K salt in the cylinder, on these was placed another layer of the Th-K salt, and the cylinder was thus nearly filled with alternate layers of Na and the double salt; the contents of the cylinder were pressed together by a piston which fitted into the cylinder, sufficient dry NaCl was added to fill the cylinder, the lid was screwed on, and the apparatus was heated to full redness for about fifteen minutes; after cooling, the contents of the apparatus were treated with cold water, whereby chlorides were dissolved and the excess of sodium was converted into NaOH and dissolved (the action is apt to be explosive); the thorium was washed with water, then with alcohol, and finally with ether, and dried at 100° .

The yield of thorium by this method is almost equal to that calculated from the equation. For a detailed description of the iron cylinder used for reduction v. Nilson a. Pettersson, *W.* 4, 554 (on the preparation of Be).

Properties.—Prepared as described, Th forms a greyish-white, glistening powder; the powder consists of small, thin, six-sided, crystalline leaflets; the larger crystals are as white and lustrous as silver, the smaller are grey and less lustrous. The crystals are somewhat brittle. S.G. at 17° 11.1 to 11.28; the latter number referring to the well-crystallised metal (Nilson, B. 15, 2543; 16, 160). S.H. (0° to 100°) .02787, hence at heat -6.4 (N., B. 16, 161). Crystallises in combinations of regular octahedra and hexahedra; isomorphous with Si (N., *l.c.*; and *note*, p. 162). S.V.S. 20.9. The emission-spectrum of Th has been mapped by Thalén (*Détermin. des Longueurs d'Onde des Raies Métalliques* [Upsala, 1868]); the most marked lines are three in the indigo; 4398, 4382, and 4281. Soret (*Ar. Sc.* [2] 68, 59; [3] 4, 94) found that ThCl_4Aq cuts off almost the whole of the ultra-violet part of the spectrum.

Th is unchanged in air up to 100° – 120° ; when heated to a higher temperature it burns to ThO_2 , with production of much white light. Th

is readily oxidised by heating in O; on this account some of the metal is oxidised in the process of preparation if the lid of the cylinder does not fit tightly. Nilson's experiments (*B.* 15, 2541) show that Th does not melt at the full heat of a wind-furnace. Th does not react with water; it combines directly with Cl, Br, I and S. The metal is slowly acted on by H_2SO_4 or HNO_3 , rapidly by HClAq or *aqua regia*; alkali solutions do not seem to react.

The at. w. of Th has been determined: (1) by analysing $\text{Th}(\text{SO}_4)_2$ and hydrates of this salt (Berzelius, *P.* 16, 398 [1829]; Chydenius, *P.* 119, 43 [1861]; Delafontaine, *Ar. Sc.* 18, 343 [1863]; Hermann, *J. pr.* 93, 114 [1864]; Cleve, *Bl.* [2] 21, 116 [1874]; Nilson, *B.* 15, 2527 [1882]; Krüss a. Nilson, *B.* 20, 1665 [1887]); (2) by analyses of the double Th-K sulphate (Berzelius, *l.c.*); (3) by analyses of the acetate, oxalate, and formate of Th (Chydenius, *l.c.*); (4) by determining S.H. of Th (Nilson, *B.* 16, 153 [1883]); (5) by finding V.D. of ThCl_4 (Krüss a. Nilson, *B.* 20, 1665 [1887]). The mol. w. of Th is not known.

Th is distinctly metallic in its chemical relations; the only oxide that has been isolated with certainty, ThO_2 , is basic, forming salts ThX_3 ($\text{X} = \text{SO}_4, 2\text{NO}_3, \text{&c.}$). There are indications of the existence of a higher oxide ($? \text{Th}_2\text{O}_3$). Thorium forms the last member of the even-series family of Group IV. in the periodic classification of the elements. The members of this family are C, Ti, Zr, Ce, —, Th. The four elements Ti, Zr, Ce, and Th closely resemble one another in their chemical properties; they are also similar to the odd-series family of Group IV., namely, Si, Ge, Sn, —, Pb. For a general account of Group IV. (and more especially of C and Si) v. CARBON GROUP OF ELEMENTS (vol. i. p. 682); for a description of the even-series family (Ti, Zr, Ce, Th) v. TITANIUM GROUP OF ELEMENTS (this vol. p. 749); and for the odd-series family (Ge, Sn, Pb; Si being described in vol. i. p. 652) v. TIN GROUP OF ELEMENTS (this vol. p. 735).

The atom of thorium is tetravalent in the gaseous molecule ThCl_4 .

Reactions and Combinations (Nilson, *B.* 15, 2541).—1. Heated in air, oxidation begins at c. 120° , and at much below red heat the metal burns brilliantly to ThO_2 .—2. Heated in a stream of oxygen, the metal burns to ThO_2 , with the production of dazzling white light.—3. Th burns to ThX , when heated in chlorine, in bromine vapour, or in vapour of iodine.—4. When heated with sulphur part of the S volatilises, and when the temperature is above the b.p. of S combination occurs with production of much light, ThS , being formed.—5. According to Troost (*C. R.* 116, 1227), Th combines with carbon, when ThO_2 is mixed with C and heated in CO_2 in the electric arc (v. Carbide, *infra*).—6. Water does not react with Th at any temperature, so far as experiments have been tried. Nilson (*l.c.*) gives no details, but says 'Thorium is not changed by water under any conditions'.—7. Sulphuric acid reacts slowly with Th; when dilute, the acid evolves H; when conc. and hot, SO_2 is given off.—8. The action of nitric acid is slight; the dilute warm acid acts very gradually; conc. acid is almost without action.—9. Hydrochloric acid rapidly dissolves Th, forming ThCl_4 , and giving off H; the action

is most complete with conc. acid.—10. *Aqua regia* dissolves Th easily.—11. Alkaline solutions seem not to react with Th.

Detection and Estimation.—Salts of Th are colourless when the acid is colourless. Alkalis, and also $(\text{NH}_4)_2\text{SAq}$, ppt. gelatinous, white $\text{ThO}_2 \cdot 2\text{H}_2\text{O}$, insoluble in excess of the precipitant; alkali carbonates form a white pp. soluble in excess; solution in $(\text{NH}_4)_2\text{CO}_3\text{Aq}$ becomes turbid at 60° , but goes clear on cooling; saturation of a solution of a salt of Th with K_2SO_4 forms white $\text{Th}(\text{SO}_4)_2 \cdot \text{K}_2\text{SO}_4 \cdot 2\text{H}_2\text{O}$, insoluble in $\text{K}_2\text{SO}_4\text{Aq}$, but soluble in water; $\text{K}_2\text{FeCy}_3\text{Aq}$ ppts. white ThFeCy_3 ; oxalic acid and alkali oxalates ppt. white amorphous $\text{Th}(\text{C}_2\text{O}_4)_2$, insoluble in dilute acids, soluble in solutions of alkali oxalates or $\text{NH}_4\text{C}_2\text{O}_4$, especially on warming.

Th is generally estimated by ppn. as $\text{ThO}_2 \cdot 2\text{H}_2\text{O}$ or $\text{Th}(\text{C}_2\text{O}_4)_2$, and subsequent conversion into ThO_2 by heating.

Thorium, bromide of. The gummy, white mass obtained by Berzelius (*P.* 16, 385), by evaporating a solution of $\text{ThO}_2 \cdot 2\text{H}_2\text{O}$ in HBrAq , was probably ThBr_3 . The hydrated salt $\text{ThBr}_3 \cdot 10\text{aq}$ seems to have been obtained, from $\text{ThO}_2 \cdot 2\text{aq}$, by Jannasch, Loocke, a. Lesinsky (*Zeit. f. anorg. Chemie*, 5, 283).

Thorium, carbide of. By heating an intimate mixture of ThO_2 and C in the electric arc, in an atmosphere of CO_2 , Troost (*C. R.* 116, 1227) obtained a hard, brittle solid, containing from 8.2 to 9.5 p.c. C, and therefore approximating to the formula ThC_2 (which requires 9.38 p.c. C). S.G. 10.15 at 15° ; scratches glass slightly; decomposes cold water, giving off H and strongly smelling hydrocarbons; gradually decomposes in moist air; burns rapidly and brilliantly when heated to redness.

Thorium, chloride of, ThCl_4 . Mol. w. 373.5. V.D. 172.2 at 1050° – 1270° (Krüss a. Nilson, *B.* 20, 1671). This compound is formed by heating a mixture of ThO_2 and C in a stream of dry Cl; the ThCl_4 sublimes in white needles. Krüss a. Nilson (*B.* 20, 1675) prepared pure ThCl_4 by heating Th to incipient redness in a stream of dry, air-free HCl; then raising the temperature to full redness, in order to sublime a little FeCl_3 , formed from the iron in the thorium used; and finally subliming the ThCl_4 at an incipient white heat. (For details of the apparatus used v. Nilson a. Pettersson, *J. pr.* [2] 33, 1 [on preparation of BeCl_2]).

ThCl_4 crystallises in lustrous, white needles; moderately hygroscopic, but remains some hours in the air before deliquescing (K. a. N., *l.c.*). Does not volatilise at c. 420° (Chydenius, *P.* 119, 43). The V.D. found by K. a. N. at temperatures from 1050° to 1270° shows that the formula ThCl_4 is molecular. K. a. N. got the value 142 for V.D. at 1400° , showing that dissociation had begun. Troost (*C. R.* 101, 360) obtained values for V.D. of ThCl_4 at c. 950° considerably lower than those of K. a. N. It is likely that his specimen was not pure, or that the apparatus used contained traces of O sufficient to cause decomposition to ThO_2 and Cl (K. a. N., *l.c.*, p. 1674).

Hydrated thorium chloride $\text{ThCl}_4 \cdot 8\text{H}_2\text{O}$ was obtained by Cleve in thin, white prisms, by concentrating a solution of $\text{ThO}_2 \cdot 2\text{H}_2\text{O}$ in HClAq ,

allowing to crystallise, and drying over H_2SO_4 (*Bl.* [2] 21, 116).

Double salts.— ThCl_3 combines with *potassium chloride* to form $2\text{ThCl}_3 \cdot \text{KCl} \cdot 18\text{H}_2\text{O}$; obtained by mixing very conc. solutions of the constituents. Forms small, white crystals; v. sol. water, also sol. alcohol; dehydrated by heating in HCl (Cleve, *Bl.* [2] 21, 116). By heating a dry mixture of ThCl_3 and NH_4Cl in HCl , Chydenius (*Bl.* [2] 1, 130; 6, 433) obtained a compound with *ammonium chloride*, which, when crystallised from water *in vacuo*, had the composition $\text{ThCl}_3 \cdot 8\text{NH}_4\text{Cl} \cdot 8\text{H}_2\text{O}$; loses $6\text{H}_2\text{O}$ at 100° . Cleve (*l.c.*) prepared a compound with *platinic chloride* $\text{ThCl}_3 \cdot \text{PtCl}_3 \cdot 12\text{H}_2\text{O}$; and Nilson (*l.c.*) a compound with *platinous chloride* $2\text{ThCl}_3 \cdot 3\text{PtCl}_2 \cdot 24\text{H}_2\text{O}$.

Thorium, ferrocyanide of, $\text{ThFeCy}_6 \cdot 4\text{H}_2\text{O}$. A white powder; prepared by adding $\text{K}_4\text{FeCy}_6\text{Aq}$ to solution of a salt of Th (Cleve, *Bl.* [2] 21, 116).

Thorium, fluoride of, $\text{ThF}_4 \cdot 4\text{H}_2\text{O}$. Obtained by adding HFAq to ThCl_3Aq ; the gelatinous pp. becomes powdery after a time (Chydenius, *Bl.* [2] 1, 130; 6, 433). Loses H_2O at 100° , and $2\text{H}_2\text{O}$ at 140° – 200° ; heated to redness gives ThO_2 and HF. Berzelius (*P.* 16, 385) obtained a heavy white powder by heating $\text{ThO}_2 \cdot 2\text{H}_2\text{O}$ with HFAq . Combines with *potassium fluoride*; Chydenius (*l.c.*) obtained two salts, (1) $\text{ThF}_4 \cdot \text{KF}$ by mixing ThCl_3Aq with KHF_4Aq , (2) $\text{ThF}_4 \cdot 2\text{KF} \cdot 4\text{H}_2\text{O}$ by boiling $\text{ThO}_2 \cdot 2\text{H}_2\text{O}$ with conc. KHF_4Aq and HFAq . The isolation of a third salt, $7\text{ThF}_4 \cdot 8\text{KF} \cdot 6\text{H}_2\text{O}$, is doubtful.

Thorium, hydride of. By heating ThO_2 with excess of Mg powder, in a stream of H, Winkler (*B.* 24, 885) obtained a grey powder, which gave off H with dilute HClAq , and burnt when heated in O. Analyses of this powder gave 72.86 p.c. Th, .50 p.c. H, 17.57 p.c. Mg, and 9.07 p.c. O. Supposing the ThO_2 , Mg, and H interacted in accordance with the equation $\text{ThO}_2 + 2\text{Mg} + 2\text{H} = \text{ThH}_2 + 2\text{MgO}$, then, from the quantities of ThO_2 and Mg used, the product would give on analysis 73.77 p.c. Th, .63 p.c. H, 15.45 p.c. Mg, and 10.15 p.c. O. From these data Winkler concluded that a hydride, ThH_2 , was formed in the reaction.

Thorium, hydroxides of, v. OXIDES AND HYDRATED OXIDES (*infra*).

Thorium, iodide of. The white gummy mass, crystallising after a time, obtained by Chydenius (*Bl.* [2] 1, 130; 6, 433) by evaporating a solution of $\text{ThO}_2 \cdot 2\text{H}_2\text{O}$ in HIAq , was probably ThI_4 . The substance goes brown in the light.

Thorium, nitride of. By heating ThO_2 or ThCl_3 in NH_3 , also by heating ThCl_3 and NH_4Cl in HCl , Chydenius (*l.c.*) obtained a small quantity of what he supposed to be either a nitride of Th or a compound of the metal with N and H.

Thorium, oxides and hydrated oxides of. Besides the oxide ThO_2 , a peroxide, probably Th_2O_5 , is said to exist.

THORIUM DIOXIDE ThO_2 (*Thoria*). Mol. w. not known. Obtained by ppg. a salt of Th by alkali, $(\text{NH}_4)_2\text{SAq}$, or KCNAq , drying, and strongly heating; also by decomposing $\text{Th}(\text{C}_2\text{O}_4)_3$ by heat. A fine, white powder. S.G. 10.23 at 17° (Nilson, *B.* 15, 2536). S.V.S. 25.87. S.H. (0° to 100°) .0548 (N. & Pettersson, *B.* 13, 1459).

By heating ThO_2 with borax in a porcelain oven, Nordenskjöld obtained the oxide in microscopic crystals isomorphous with SnO_2 and ZrO_2 (*P.* 150, 219). ThO_2 has not been fused; it is not reduced by heating with C, but when mixed with C and heated in Cl the chloride ThCl_3 is obtained. ThO_2 does not react with molten alkalis. It is scarcely acted on by acids; warm conc. H_2SO_4 , however, converts it into $\text{Th}(\text{SO}_4)_2$.

HYDRATES OF THORIUM DIOXIDE. The *dihydrate* $\text{ThO}_2 \cdot 2\text{H}_2\text{O}$ ($= \text{ThO}_2\text{H}_4$, *thorium hydroxide*) is obtained by ppg. a solution of a salt of Th by an alkali, $(\text{NH}_4)_2\text{SAq}$, or KCNAq , washing, and drying at 100° . It forms a hard, white solid. $\text{ThO}_2 \cdot 2\text{H}_2\text{O}$ combines with CO_2 in the air; it dissolves in acids, forming salts ThX_2 , where $\text{X} = \text{SO}_4$, 2NO_3 , &c. Another hydrate, $4\text{ThO}_2 \cdot \text{H}_2\text{O}$ ($= \text{Th}_4\text{O}_{11}$, *thorium metahydroxide*) is obtained, according to Cleve (*Bl.* [2] 21, 116), by heating ThO_2 (obtained by decomposition of $\text{Th}(\text{C}_2\text{O}_4)_3$) with excess of HNO_3Aq or HClAq at 100° till the acid is driven off, adding water, and then ppg. the opalescent solution so obtained by NH_4Aq , washing, and drying at 100° . This hydrate is said to be insoluble in dilute acids.

THORIUM PEROXIDE Th_2O_5 . An oxide with this composition is said to be produced by adding $\text{H}_2\text{O}_2\text{Aq}$ and NH_4Aq to a solution of a salt of Th (Cleve, *Bl.* [2] 43, 53; Leooq de Boisbaudran, *C. R.* 100, 605).

Thorium, oxysulphide of. By strongly heating ThO_2 , obtained from $\text{ThO}_2 \cdot 2\text{H}_2\text{O}$, in CS_2 vapour, Chydenius (*Bl.* [2] 1, 130; 6, 433) obtained a solid substance to which he gave the formula $2\text{ThO}_2 \cdot \text{ThS}_2 = \text{Th}_3\text{O}_5\text{S}_2$. According to Krüss a. Volk (*Zeit. f. anorg. Chemie*, 5, 75; 6, 49), the compound obtained by heating ThO_2 in CS_2 is ThOS , and the same compound is formed by heating $2\text{ThCl}_3 \cdot \text{KCl}$ in H_2S .

Thorium, phosphide of. By heating Th in vapour of P, Berzelius (*P.* 16, 385) obtained a dark grey, metal-like, lustrous solid, which was changed to Th phosphate by heating in air.

Thorium, platinoeyanide of, $\text{Th}(\text{PtCy})_6 \cdot 16\text{H}_2\text{O}$. Yellow-green, orthorhombic prisms (Cleve, *Bl.* [2] 21, 116).

Thorium, salts of. All the normal compounds which have been isolated by replacing H of acids by Th belong to the class ThX_2 , where $\text{X} = 2\text{NO}_3$, 2IO_3 , SO_4 , SO_3 , $\frac{2}{3}\text{PO}_4$, &c.; basic salts also exist. The chief salts of oxyacids are *borate, carbonate, chlorate, chromate, iodate and periodate, molybdate, nitrate, oxalate, phosphates, selenate and selenites, silicates, sulphate and sulphite, and tartrate*.

Thorium, silicofluoride of. By treating $\text{ThO}_2 \cdot 2\text{H}_2\text{O}$ with $\text{H}_2\text{SiF}_6\text{Aq}$, Cleve (*Bl.* [2] 21, 116) obtained a semi-transparent, crystalline solid, probably $\text{Th}(\text{SiF}_6)_3$; insol. in excess of H_2SiF_6 ; over H_2SO_4 gave off HF and SiF_4 .

Thorium, sulphide of, ThS_2 . Obtained by heating Th with S; excess of S sublimes, and when the temperature passes the b.p. of S the elements combine with evolution of heat and light (Nilson, *B.* 15, 2542; cf. Berzelius, *P.* 16, 385). Also formed by heating ThO_2 , obtained from $\text{Th}(\text{C}_2\text{O}_4)_3$, to white heat in vapour of CS_2 (Chydenius, *Bl.* [2] 1, 130; 6, 433); but, according to Krüss a. Volk (*l.c.*), the compound thus formed is ThOS . A black powder. Burns when heated in air, giving off SO_2 and leaving

ThO₂. Not acted on by HClAq or HNO₃Aq; *aqua regia* dissolves the compound, forming Th(SO₄)₂. Molten KOH forms K₂S and ThO₂; heating in Cl produces ThCl₄.

Thorium, sulphocyanide of. The salt [Th(SCy)]₂ is obtained, as a viscid mass, by evaporating a solution of ThO₂.2H₂O in HSCNAq. A solution of the compound gives a pp. with HgCy₂, said to be Th(OH)(SCy).HgCy₂.H₂O; and the filtrate is said to give crystals of Th(OH)(SCy).3HgCy₂.12H₂O (Cleve, *Bl.* [2] 21, 116).

M. M. P. M.

THUJIGENIN C₁₅H₂₂O₂ or C₁₅H₂₀O₂. Occurs in small quantity in *Frondes Thuja*, the green parts of *Thuja occidentalis* (Roehleider a. Kawalier, *Sitz.* W. 29, 10). Minute needles, v. sl. sol. water, sol. alcohol. NH₃ colours its alcoholic solution green. AcCl forms resinous C₁₅H₂₁AcO₂.

THUJIN C₁₅H₂₂O₁₂. Occurs in the green branches of *Thuja occidentalis* (Roehleider a. Kawalier, *Sitz.* W. 29, 10). Minute lemon-yellow four-sided tables, sol. alcohol. Tastes bitter. Its alcoholic solution is coloured yellow by alkalis, is turned reddish-brown by air, gives a yellow pp. with lead acetate, and gives a dark-green colour with FeCl₃. Reduces ammoniacal AgNO₃. Boiling dilute H₂SO₄ turns it first green, then yellow, and splits it up into sugar and thujetin. Boiling baryta-water hydrolyses it in like manner.

Thujetin C₁₅H₂₂O₁₂. Yellow solid, nearly insol. water, sol. alcohol and ether. Not altered by dilute HCl or H₂SO₄. Its alcoholic solution is turned a splendid bluish-green colour by NH₃Aq. Gives, in alcoholic solution, a red pp. with lead acetate, and a black colour with FeCl₃. Boiling baryta-water converts it into thujetic acid C₁₅H₂₂O₁₂, which crystallises in minute lemon-yellow needles, sol. alcohol and ppd. by water.

(B)-THUJOL is TANACETONE.

THUJONE C₁₀H₁₆O. (212°). S.G. 22-9265. Occurs, together with the terpene C₁₀H₁₆, and *lavoratory fenchone*, in the essential oil of *thuja* obtained by distilling the ends of the branches and the leaves of *Thuja occidentalis* with water (Schweizer, *A.* 51, 898; Jahns, *Ar. Ph.* 221, 748; Wallach, *A.* 272, 109). Yields an oxim.

Reactions.—1. When heated with *ammonium formate* it yields a formyl derivative which on saponification gives rise to 'thujoneamine' C₁₀H₁₇NH₂ (199°), which forms the salts B'H₂PtCl₆ and B'HCl. Thujone-amine hydrochloride decomposes on distillation into NH₄Cl and thujene C₁₀H₁₆ (c. 173°), S.G. 22-84.—2. KMnO₄ forms two 'thujaketic acids'.—3. Br forms C₁₀H₁₁Br₂O [122°] (Wallach, *A.* 275, 179).

(a)-Thujaketic acid C₁₀H₁₆O₂ i.e. CH₃.COO.C₈H₁₂.CO₂H. [76°]. S. c. 2-5 at 100°. Transparent plates. Yields an oxim [c. 186°].

(B)-Thujaketic acid C₁₀H₁₄(OO.CH₃).CO₂H. [79°]. S. 1-43 at 100°. Small matted needles. On distillation it yields methyl heptyl ketone (186°) S.G. 22-854, which gives *p*-cymene dihydride C₁₀H₁₆, on heating with ZnCl₂ at 100° (Wallach, *A.* 275, 166). Forms an oxim [106°] which crystallises in needles.—AgA': v. sl. sol. cold water.

THULIUM. This name was given by Cleve in 1879 to the metal of a new earth which he announced to be present in specimens of *gadolinite* (C. R. 89, 478). The name thulium was derived from *Thule*, the old name for Scandinavia. The presence of the new earth was more or less confirmed by the work of Nilson (*B.* 13, 1433), and of Soret (C. R. 89, 261). In 1880 Cleve said he had isolated *thulia*, and described it as a white earth, giving an emission spectrum characterised by two bright lines 5896 and 5306, and forming solutions of salts which showed two absorption bands 6840 and 4645. To this earth Cleve assigned the formula Tm₂O₃, and he determined the maximum value of the atomic weight of the supposed element to be Tm = 170.7. In 1888 Krüss a. Nilson declared that thulium consists of two distinct elements (*B.* 21, 1681).

The absolute homogeneity of thulia has been by no means established (*v.* METALS, RARE, vol. iii. p. 245).

M. M. P. M.

THYME OIL. The essential oil from garden thyme, *Thymus vulgaris*, contains *lavoratory* thymene C₁₀H₁₆ (160°-165°), thymol C₁₀H₁₄O and a little cymene (Lallemand, *A.* 102, 119; *A. Ch.* [3] 49, 155). The oil from wild thyme, *Thymus serpyllum*, contains cymene, thymol, carvacrol, and a phenol coloured violet by FeCl₃ (Jahns, *Ar. Ph.* [3] 16, 277; Febre, *C. R.* 92, 1290; Buri, *Ar. Ph.* [3] 12, 485).

THYMO-ACRYLIC ACID v. OXY-OTMYL-ACRYLIC ACID.

THYMOHYDROQUINONE v. HYDROTHYMO-QUINONE.

THYMOL C₁₀H₁₄O i.e. C₆H₅MePr.OH [5:2:1]. Mol. w. 150. V.D. 75-3 (calc. 75) (Eykmán, *B.* 22, 2757). [49-5°] (Reissert, *B.* 23, 2242). (232°). S.G. 2-9941. O.E. (0°-10°) 00085. S. 3. S.V. 188-9 (Pinette, *A.* 243, 46); 189-3 (Ramsey). R₂₀ = 76-56 (Nasini a. Bernheimer, *G.* 15, 93). H.F.p. (liquid) 69,250; (solid) -8768. Occurs in essential oil of thyme (Dover, *A.* 64, 374; Lallemand, *A. Ch.* [3] 49, 148; *A.* 102, 119), of horsemint, *Monarda punctata* (Arppe, *A.* 58, 42), of *Psychotis ajowan* (Stenhouse a. Haines, *A.* 98, 307; H. Müller, *B.* 2, 130) of *Monarda Didyma*, of *Ammi Copticum* (Buri, *Ar. Ph.* [3] 12, 485), and in the oil from wild thyme (Jahns, *B.* 15, 819).

Formation.—By boiling diazo-*n*-cymene with water (Widman, *B.* 15, 170; 19, 245).

Preparation.—By extracting oil of thyme with NaOHAq, ppd. by HCl, and recrystallising from HOAc.

Properties.—Plates (from alcohol), v. sl. alcohol, ether, and HOAc, v. sl. sol. water. Has a slight odour of thyme and a peppery taste. When solid it is slightly heavier than water, when liquid it is lighter. Not ppd. by adding water to its alcoholic solution. Not dissolved by NH₃Aq, but absorbs NH₃, becoming liquid, but re-solidifying after the NH₃ has escaped. Sol. KOHAq. FeCl₃ does not colour its aqueous solution. Bromine-water only gives a milkiness. An aqueous solution (1 vol.) warmed first with HOAc (½ vol.) and then with H₂SO₄ (1 vol.) is coloured reddish-violet, the solution showing two absorption bands at E and D (Wolff, *Fr.* 22, 96). KOHAq followed by I in KI gives on warming a fugitive red tint (Itallie, *Fr.* 29, 205).

Estimation: Messinger, *B.* 23, 2754.

Reactions.—1. Decomposed by distilling with P_2O_5 into propylene and *m*-cresol.—2. P_2S_5 yields cymene (Fittica, *B.* 6, 938; *A.* 172, 305).—3. Oxidised by *chromic acid* to thymoquinone.—4. $POCl_3$ yields chloro-cymene.—5. *Potash-fusion* yields several oxy-acids (Barth, *B.* 11, 567, 1571).—6. *Iodine* and *potash* yield a red amorphous pp. [110°] converted by heat or by boiling water into a yellow body [165°] (Messinger & Vortmann, *B.* 22, 2316).—7. Boiling $POCl_3$ (1 mol.) acting on thymol (1 mol.) forms liquid $C_{10}H_{13}O.POCl_2$ (280°–285°) which is converted by water into liquid $C_{10}H_{13}O.PO(OH)_2$, which yields BaA'' 4aq and is decomposed by heat into thymol and HPO_3 (Discalzo, *G.* 15, 279).—8. Boiling $POCl_3$ acting on thymol (2 mols.) forms $(C_{10}H_{13}O)_2POCl$ (330°–340° at 320 mm.), a liquid which is converted by water into $(C_{10}H_{13}O)_2PO.OH$, which is insol. water and yields NaA' [74°] (Kreysler, *B.* 18, 1705) and BaA' 5aq. *S.* 197 at 21°.—9. PCl_5 (1 mol.) acting on thymol (4 mols.) forms $(C_{10}H_{13}O)_4PO$ [59°] crystallising from alcohol in prisms (E. a. L.).—10. $SiCl_4$ forms $Si(OC_{10}H_{13})_4$ [48°] (450°) crystallising from $CHCl_3$ in prisms (Hertkorn, *B.* 18, 1693).—11. $Cl.CO.NH_2$ reacts forming $C_{10}H_7MePr.O.CO.NH.CO.NH_2$ [190°] (Gattermann, *A.* 244, 44).—12. $C_6H_5(NMe_2)(NH_2)$ [1:4] forms indothymol $C_6H_5(NMe_2)N < C_{10}H_7MePr$

[69·5°] crystallising in needles, insol. water and alkalis, forming a blue solution in alcohol, a violet in ether, and a green in $HOAc$. $HClAq$ decomposes indothymol into thymoquinone, dimethyl-aniline, and NH_3 (Bayrac, *Bl.* [3] 7, 97).—13. *Chloral* forms $C_{10}H_{13}OC.HClO$ [130°–134°] (Mazzara, *G.* 13, 272).—14. *Chloral*, conc. H_2SO_4 , and $HOAc$ yield $CCl_3.CH(C_{10}H_{13}OH)_2$ (Jäger, *B.* 7, 1197).—15. Dilute H_2SO_4 gradually added to a mixture of benzoic aldehyde (1 mol.) and thymol (2 mols.) forms $C_6H_5.CH(C_{10}H_{13}OH)_2$ [146°] which is sol. alkalis and yields a diaetyl derivative [126°] (Russanoff, *B.* 22, 1943).—16. $COCl_2$ passed into an aqueous solution of $C_{10}H_{13}ONa$ forms di-thymyl carbonate $(C_{10}H_{13}O)_2CO$ which crystallises from alcohol in needles [48°] (above 360°) and yields *o*-oxy-benzoic acid when heated with $NaOPh$ at 180° (Richter, *J. pr.* [2] 27, 505). According to Bender (*B.* 19, 2268), di-thymyl carbonate, prepared by heating thymyl ethyl carbonate at 300°, melts at 60°. $COCl_2$ also forms, as a by-product, $C_{10}H_{13}O.COCl$, which is converted by ammonia into $C_{10}H_{13}O.CO.NH_2$ [131°].—17. $Cl.CO_2Et$ acting in the cold upon $C_{10}H_{13}ONa$ forms $C_{10}H_{13}O.CO_2OEt$ (c. 261°), an oil which yields *o*-oxy-benzoic acid, $PhOEt$, and thymol when heated with $NaOPh$ (Richter).—18. Treatment with $ClCH_2.CO_2H$ and $NaOHAq$ produces $C_{10}H_{13}O.CH_2.CO_2H$ [148°] which yields BaA' 2aq, PbA' , AgA' , oily EtA' (290°), and an amide [97°] (Saarbach, *J. pr.* [2] 21, 159; Spica, *G.* 10, 342).—19. *α-Chloropropionic acid* and $KOHAq$ yield $C_{10}H_{13}O.CHMe.CO_2H$ [48°] (Seichilone, *G.* 12, 50).—20. Thymol (10 g.) mixed with H_2SO_4 (70 g.) containing nitrous acid gives thymol-chroin $C_{10}H_{13}N_2O_2$, a dark-violet amorphous body which dissolves in alcohol, ether, $CHCl_3$, and benzene, forming red solutions with pale-green fluorescence. Alkalis turn its alcoholic solutions blue. Sublimes at 140°, giving off violet vapours.

Yields brown amorphous $C_{10}H_{13}Ac_2N_2O_2$ (Brummer a. Chuit, *B.* 21, 252; cf. Liebermann, *B.* 7, 1100).—21. By heating with ammonium-zinc chloride it is converted into thymylamine $C_{10}H_{13}NH_2$, and di-thymylamine $(C_{10}H_{13})_2NH$.—22. *Cyanuric chloride* converts sodium thymol into $(C_{10}H_{13})_3CN_3O_2$ [151°] a yellow crystalline powder, insol. water, al. sol. alcohol (Otto, *B.* 20, 2239).—23. Aqueous KOH and $K_2S_2O_8$ form $C_{10}H_{13}O.SO_2.OK$, which crystallises from alcohol in slender silky threads (Heymann a. Königs, *B.* 19, 3307). It is oxidised by alkaline $KMnO_4$ to oxyeuminic acid $C_{10}H_7Pr(OH).CO_2H$ [4:3:1].

Salts.— $C_{10}H_{13}ONa$. Crystalline. Its aqueous solution is ppd. by $HgCl_2$ and $AgNO_3$.— $C_{10}H_{13}O.Hg.HgNO_3$.— $C_{10}H_{13}O.Hg.HgOAc$ (Merck, *G. P.* 48539; *Pharm. Zei.* 1889, 625).— $(C_{10}H_{13}O)_2Hg_2$ (Lallemand).— $(C_{10}H_{13}O)_4Al$. Decomposed by heat into propylene and $(C_{10}H_7Me.O)_3Al$, the *m*-cresylate then splitting up into alumina, *m*-cresol, di-*m*-tolyl oxide, and a body $C_{10}H_{13}O$ [200°] *S.* (alcohol) ·17 at 20°; 1 at 78°; *S.* (benzene) ·93 at 21°; *S.G.* ·805; *V.D.* 208·8, crystallising in pearly plates (Gladstone a. Tribe, *C. J.* 39, 9; 41, 11).

Acetyl derivative $C_{10}H_{13}OAc$. (245°). *S.G.* 1·009.

Benzoyl derivative $C_{10}H_{13}OBz$. [32°]. *H.F.* 90,480 (Stohmann, *J. pr.* [2] 36, 9).

Methyl ether $C_{10}H_{13}OMe$. (216° cor.). *S.G.* ·9531. *C.E.* (0°–10°) ·00083. *S.V.* 214·3 (Pinette, *A.* 248, 47). *H.F.p.* 61,429 [$C_{10}H_{13}O$ = 94,000; H_2O = 69,000] (Stohmann, *J. pr.* [2] 35, 26). Formed from thymol, KOH , and MeI (Engelhardt a. Latschinoff, *Z.* [2] 5, 43).

Ethyl ether $C_{10}H_{13}OEt$. (227°) (Pinette; cf. Jungfleisch, *Bl.* [2] 4, 17). *S.G.* ·9334. *C.E.* (0°–10°) ·00089. *S.V.* 240. *H.F.p.* 68,858 (Stohmann). Yields the ethyl derivative of oxyterephthalic acid on oxidation (Paterno a. Canzoneri, *G.* 9, 460). Decomposes at 360°–400° into thymol and ethylene (Bamberger, *B.* 19, 1820).

Propyl ether $C_{10}H_{13}OPr$. (243°). *S.G.* ·9276. *C.E.* (0°–10°) ·00088. *S.V.* 265·5.

Butyl ether $C_{10}H_{13}OC_4H_9$. (258°). *S.G.* ·9230. *C.E.* (0°–10°) ·00085. *S.V.* 289·2.

Isoamyl ether $C_{10}H_{13}OC_5H_{11}$. (238°–243°) (E. a. L.). Oil.

Heptyl ether $C_{10}H_{13}OC_7H_{15}$. (307°). *S.G.* ·9097. *C.E.* (0°–10°) ·00082. *S.V.* 368·7.

Octyl ether $C_{10}H_{13}OC_8H_{17}$. (320°). *S.G.* ·9026. *C.E.* (0°–10°) ·00075. *S.V.* 395·6 (Pinette).

Ethylene ether $(C_{10}H_{13}O)_2C_2H_4$. [99°]. Plates (from ether) (Paterno, *G.* 5, 13).

Nitroso-thymol v. Oxim of THYMOQUINONE.

Dithymol v. Di-oxy-di-thymyl.

References.—*Amido*-, *Bromo-amido*-, *Bromo-nitro*-, *Tri-chloro*-, *Iodo*-, *Iodo-amido*-, and *Nitro-thymol*.

DI-THYMOL-ETHANE v. DI-OXY-DI-CYMYL-ETHANE.

THYMOL DICARBOXYLIC ALDEHYDE $C_{10}H_{13}O_2$ i.e. $C_6HMePr(OH)(CHO)_2$ [80°]. Formed as a by-product in the preparation of thymotic acid by the action of chloroform and $NaOH$ on thymol (Kobek, *B.* 16, 2104). Needles. Gives a red colour with $FeCl_3$.

THYMOL (α)-SULPHONIC ACID

$C_{10}H_7MePr(OH).SO_3H$. [92°] (Stebbins, *Am.* 8, 111). Formed from thymol by the action of

H_2SO_4 or $\text{Cl}_2\text{SO}_3\text{OH}$ at 50° (Engelhardt a. Latschinoff, *Z.* 1869, 44; 1871, 261). Pearly plates (containing aq), v. e. sol. water. FeCl_3 colours neutral solutions dark-violet. Yields thymoquinone on oxidation.

Salts.— KA'_2 2aq. Efflorescent tables, v. e. sol. water.— NaA'_2 2aq. [167°].— $\text{NH}_4\text{A}'_2$ 2aq. [172°].— CaA'_2 2aq. [157°].— BaA'_2 4aq. Prisms, decomposing at 100° .— PbA'_2 4aq.

Benzoyl derivative $\text{C}_{10}\text{H}_{12}(\text{OBz})\cdot\text{SO}_3\text{H}$.— KA'_2 2aq.— CaA'_2 4aq.— BaA'_2 6aq.— PbA'_2 6aq.

Ethyl derivative $\text{C}_{10}\text{H}_{12}(\text{OEt})\text{SO}_3\text{H}$. Formed from the K salt, KOH , and EtI .— KA' . Thin plates.— BaA'_2 3aq. Plates, sl. sol. hot aq.

Isoamyl derivative $\text{C}_{10}\text{H}_{12}(\text{OC}_4\text{H}_9)\text{SO}_3\text{H}$.— KA' . Needles, v. sol. water.— BaA'_2 3aq.

Thymol (β)-sulphonic acid $\text{C}_{10}\text{H}_{12}(\text{OH})\text{SO}_3\text{H}$. Formed in small quantity by the action of H_2SO_4 on thymol.— KA' aq. Plates, sl. sol. cold water. Coloured violet-blue by FeCl_3 .

Thymol (γ)-sulphonic acid $\text{C}_{10}\text{H}_{12}(\text{OH})\text{SO}_3\text{H}$. Formed by heating thymol with fuming H_2SO_4 at 100° (E. a. L.).— KA' aq. Granular, v. sol. water.— BaA'_2 3aq. Tufts of needles, more soluble than the (α)-isomeride. Not decomposed at 120° .

Benzoyl derivative $\text{C}_{10}\text{H}_{12}(\text{OBz})\text{SO}_3\text{H}$.— KA' 3aq. Flat needles, sl. sol. cold water.

Ethyl derivative $\text{C}_{10}\text{H}_{12}(\text{OEt})\text{SO}_3\text{H}$.— KA' . Flat needles.— BaA'_2 3aq. Six-sided tables.

Thymol-sulphonic acid

Ethyl derivative $\text{C}_6\text{H}_5\text{MePr}(\text{OEt})\text{SO}_3\text{H}$ [$1:4:3:6$]. Formed by boiling diazo-cymene-sulphonic acid with absolute alcohol.— BaA'_2 8aq: white plates, sol. hot water, sl. sol. cold (Widman, *B.* 19, 247).

Thymol sulphonic acid. Methyl derivative $\text{C}_{10}\text{H}_{12}(\text{OMe})\text{SO}_3\text{H}$. Formed, together with an isomeride, by sulphonation of the methyl ether of thymol (E. a. L.; Paterno a. Pisati, *B.* 8, 440).— KA' : large tables.— BaA'_2 3aq. Nodules, v. sol. hot water. S. $8:94$ at 26° .

Thymol disulphonic acid $\text{C}_{10}\text{H}_{11}(\text{OH})(\text{SO}_3\text{H})_2$. Formed by sulphonating thymol.— $\text{K}_2\text{A}''$ $1\frac{1}{2}$ aq. Efflorescent needles (from alcohol), v. e. sol. water.

References.—AMIDO-, BROMO-, and IODO-THYMOL SULPHONIC ACID.

THYMOQUINONE $\text{C}_{10}\text{H}_{12}\text{O}_2$ i.e. $\text{C}_6\text{H}_5\text{MePrO}_2$ [$2:5:4:1$]. Mol. w. 164. [$45:5^\circ$]. (232°). Formed by oxidation of thymol (Lallemand, *J.* 1854, 592), of the methyl ether of thymol (Paterno, *B.* 8, 440), of cymenol (Carstanjen, *J. pr.* [2] 8, 58; 15, 410), of di-oxy-di-cymyl-ethane (Steiner, *B.* 11, 289), of carvacrol *p*-sulphonic acid (Claus, *J. pr.* [2] 89, 356), and of amido-thymol (Andersen, *J. pr.* [2] 23, 172; Armstrong, *B.* 10, 297; Liebermann a. Ilinski, *B.* 18, 3194). Yellow crystals, with pungent odour, v. sl. sol. water, v. sol. alcohol and ether. Reduced by SO_2 to hydrothymoquinone. K_2SO_4 at 60° forms crystalline $\text{C}_{10}\text{H}_{12}\text{O}_2\text{SK}$. Phenyl cyanate forms $\text{C}_{10}\text{H}_{12}\text{O}_2\text{NO.CO.NEPh}$ [182°], crystallising in large yellow needles (Goldschmidt a. Strauss, *B.* 22, 3106).

Oxim $\text{C}_6\text{H}_5\text{MePr}(\text{NOH})$ or $\text{C}_6\text{H}_5\text{MePr}(\text{OH})(\text{NO})$. **Nitroso-thymol**. [162°]. Formed by the action of nitrous acid on thymol (R. Schiff, *B.* 8, 1500; Widmann, *B.* 15, 170; Liebermann, *B.* 18, 3194). Formed also by the action of hydroxylamine hydrochloride on

thymoquinone (Goldschmidt a. Schmid, *B.* 17, 2061). Slender monoclinic needles, $a:b:c = 1:987:1:18941$; $\beta = 94^\circ 57'$ (Panebianco, *G.* 10, 78); sl. sol. hot water. Its alkaline solution is red. Oxidised by alkaline K_2FeO_4 to nitro-thymol. Reduced by tin and HCl to amido-thymol (Liebermann, *B.* 10, 77). Does not react with SO_2 (Schmidt, *J. pr.* [2] 44, 521). Fuming HCl forms di-chloro-thymoquinone and chloro-amido-thymol (Sutkowski, *B.* 19, 2315). KOH and BzCl form $\text{C}_{10}\text{H}_{12}\text{O}(\text{NOBz})$ [110°]. Hydroxylamine (8 mols.) in strongly alkaline solution forms, in 48 hours, a white substance which, if ppd. by HAc , immediately dissolved in dilute NaOH , treated with an equal weight of a phenol, and exposed to the air, gives a deep-blue colour or pp. turned red by acids (Kehrmann a. Mesinger, *B.* 23, 2818, 3557).

Di-oxim $\text{C}_{10}\text{H}_{12}\text{N}_2\text{O}_2$ i.e. $\text{C}_{10}\text{H}_{12}(\text{NOH})_2$. Formed by boiling an alcoholic solution of nitroso-thymol (1 mol.) with hydroxylamine hydrochloride (2 mols.) and partially neutralising with alkali from time to time. Yellowish-white granules, decomposing at 235° without melting. Insol. water and NH_3 aq, sol. KOH aq.

Chlorimide $\text{C}_6\text{H}_5\text{MePr} \begin{smallmatrix} \text{O} \\ \diagup \text{NCl} \diagdown \end{smallmatrix}$. Formed

by adding a solution of bleaching powder to a cold acidified solution of the hydrochloride of *p*-amido-thymol (Andersen, *J. pr.* [2] 23, 169). Pungent oil, volatilising even at 15° . Decomposes at 160° – 170° . Volatile with steam. Decomposed by conc. HCl aq into chloro-amido-thymol and mono- and di-chloro-thymoquinone. Conc. HBr aq behaves in a precisely similar way. Alcohol at 140° converts the chlorimide into thymoquinone. Conc. aqueous SO_2 reduces it in a few days to hydrothymoquinone. Reduced by tin and HCl to *p*-amido-thymol, considerable quantities of hydrothymoquinone being formed at the same time.

Polymeride [201°]. Formed by the action of daylight on thymoquinone (Armstrong, *B.* 10, 297; Liebermann, *B.* 10, 2177; 18, 3193). Silky yellow needles (from alcohol), insol. ether. Changes to thymoquinone on distillation. Not attacked by SO_2 at 180° , but reduced by HI and P , or in alcoholic solution, by Zn and HCl aq to hydrothymoquinone.

Phenyl hydrazide [249°]. Insol. benzene. **Oxim** ($\text{C}_{10}\text{H}_{12}\text{NO}_2$)₂. [263°]. Crystalline, insol. water. Reduced by tin and HCl to amido-hydrothymoquinone.

Dioxim ($\text{C}_{10}\text{H}_{12}\text{N}_2\text{O}_2$)₂. [$c. 290^\circ$]. Powder. May be reduced to di-amido-cymene.

References.—DI-AMIDO-, BROMO-, CHLORO-, IODO-, and OXY-THYMOQUINONE.

o-THYMOTIC ACID $\text{C}_{11}\text{H}_{14}\text{O}_2$ i.e. $\text{C}_6\text{H}_5\text{Me}(\text{C}_2\text{H}_5)(\text{OH})\text{CO}_2\text{H}$ [$6:3:2:1$]. Mol. w. 194. [123°]. Formed by the action of CO_2 upon heated sodium-thymol (Kolbe a. Lautemann, *A.* 115, 205; Kobek, *B.* 16, 2101). Silky crystals, v. sol. alcohol, ether, and benzene, almost insol. cold water. Volatile with steam. Gives a deep-blue colour with FeCl_3 . Yields thymol when distilled with baryta. POCl_3 acting on the Na salt forms thymotide $\text{C}_{11}\text{H}_{13}\text{O}_2$ [187°], which is reconverted into thymotic acid by potash fusion (Naquet, *Bl.* 4, 92).

p-Thymotic acid $\text{C}_{11}\text{H}_{14}\text{O}_2$ i.e. $\text{C}_6\text{H}_5\text{Me}(\text{C}_2\text{H}_5)(\text{OH})\text{CO}_2\text{H}$ [$6:8:4:1$]. [157°]

Formed by heating thymol with aqueous NaOH and CCl_4 (Kobek). White plates, v. sol. alcohol, ether, and benzene, insol. cold water. Not coloured by FeCl_3 .

Methyl derivative

$\text{C}_6\text{H}_7\text{Me}(\text{C}_2\text{H}_5)(\text{OMe})\text{CO}_2\text{H}$. [137°]. Silky needles (from dilute alcohol).— AgA' : pp.

p-THYMOTIC ALCOHOL $\text{C}_{11}\text{H}_{16}\text{O}$, *i.e.*

$\text{C}_6\text{H}_7\text{Me}(\text{C}_2\text{H}_5)(\text{OH})\text{CH}_2\text{OH}$. [120°–130°]. Formed by reducing thymotic aldehyde with sodium-amalgam (Kobek, *B.* 16, 2098). Amorphous powder, v. sol. alcohol and ether, insol. water.

p-THYMOTIC ALDEHYDE $\text{C}_{11}\text{H}_{14}\text{O}_2$, *i.e.*

$\text{C}_6\text{H}_7\text{Me}(\text{C}_2\text{H}_5)(\text{OH})\text{CHO}$ [6:3:4:1]. [133°]. Formed, together with $\text{C}_6\text{H}_7\text{Me}(\text{C}_2\text{H}_5)(\text{OH})(\text{CHO})_2$ [6:3:4:5:1] [80°], by heating thymol with chloroform and NaOHaq (Kobek, *B.* 16, 2096). Silky needles, v. sol. alcohol, sl. sol. hot water. On heating with aniline it yields the compound $\text{C}_6\text{H}_7\text{Me}(\text{C}_2\text{H}_5)(\text{OH})\text{CH:NPh}$ [142°] crystallising in yellow needles.

Methyl derivatives

$\text{C}_6\text{H}_7\text{Me}(\text{C}_2\text{H}_5)(\text{OMe})\text{CHO}$. (278°). Formed by methylation of the aldehyde. Oil, yielding an anilide $\text{C}_6\text{H}_7\text{Me}(\text{C}_2\text{H}_5)(\text{OMe})\text{CH:NPh}$ [80°] crystallising in transparent tables.

THYMYLAMINE $\text{C}_{10}\text{H}_{15}\text{NH}_2$. (230°). Formed, together with di-thymylamine, by heating thymol with ammoniacal ZnBr_2 or ZnCl_2 and NH_4Br or NH_4Cl at 350°–360°, the yield being 25 p.c. (Lloyd, *B.* 20, 1260). Colourless oil.— $\text{B}_2\text{H}_6\text{PtCl}_6$: yellow needles.

Acetyl derivative $\text{C}_{10}\text{H}_{13}\text{NAc}$. [112°].

Isomeride v. CARVACRYLAMINE.

Di-thymyl-amine $(\text{C}_{10}\text{H}_{13})_2\text{NH}$. (340°–345°). Formed as above, the yield being 25 p.c. Oil. Its solution in P_2SO_5 is coloured blue by nitrites or nitrates.— $\text{B}_2\text{H}_6\text{PtCl}_6$.

Acetyl derivative $(\text{C}_{10}\text{H}_{13})_2\text{NAc}$. [78°].

THYMYL CYANURIC ACID *v.* CYANIC ACID.

THYMYL MERCAPTAN $\text{C}_{10}\text{H}_{13}\text{SH}$. *Thiothymol*. (281°). S.G. .989. Formed by heating thymol with P_2S_5 (Fittica, *A.* 172, 325; Bechler, *J. pr.* [2] 8, 167). Liquid with pungent odour. Oxidised by HNO_3 to sulpho-toluic acid.— $\text{Hg}(\text{SO}_4\text{H}_{13})_2$. Greenish rhombohedra [78°].— PbA'_2 : golden needles (from alcohol).

THYMYL PHOSPHATE $(\text{C}_{10}\text{H}_{13})_2\text{PO}_4$. [59°]. Formed by heating thymol with POCl_3 , the yield being 75 p.c. of the theoretical amount (Kreysler, *B.* 18, 1705). Colourless needles.

THYMYL SILICATE $(\text{C}_{10}\text{H}_{13})_2\text{SiO}_4$. [48°]. (c. 450°). Formed by heating thymol with SiCl_4 , the yield being 70 p.c. of the theoretical amount (Hertkorn, *B.* 18, 1692).

TIGLIC ACID $\text{C}_8\text{H}_{14}\text{O}_2$, *i.e.* $\text{CH}_3\text{CH:CHMe.CO}_2\text{H}$. *Methyl-crotonic acid*. Mol. w. 100. [65°]. (199° i.v.) (Kopp, *A.* 195, 84). Occurs as a glyceryl ether in croton oil (Geuther & Fröhlich, *Z.* 1870, 549; Schmidt & Berendes, *A.* 191, 94; *B.* 10, 835; *Ar. Ph.* [8] 13, 213), and as isoamyl ether in Roman oil of chamomile (Köbig, *A.* 195, 101).

Formation.—1. By the action of heat or of conc. H_2SO_4 on angelic acid (Demarçay, *B.* 9, 1933).—2. By reducing the dibromide of angelic acid with sodium-amalgam (Schmidt, *A.* 208, 253).—3. From $\text{CetMe}(\text{OH})\text{CO}_2\text{Et}$ (derived from oxalic ether, EtI , MeI , and Zn) by treatment with PCl_5 and saponification of the product

(Frankland & Duppa, *A.* 186, 9).—4. By distilling $\text{CH}_3\text{CH}(\text{OH})\text{CHMe.CO}_2\text{H}$ (Rohrbeck, *A.* 188, 235), or by heating it with HIAq (Rücker, *A.* 201, 61).—5. By reducing methyl-acetoacetic ether with sodium-amalgam and heating the resulting $\text{CH}_3\text{CH}(\text{OH})\text{CHMe.CO}_2\text{H}$ at 200° (Wislizenus, *A.* 250, 243).—6. By heating veratrine with alcoholic potash (Wright & Luff, *C. J.* 33, 347).—7. By heating veratrine with conc. HClAq (Ahrens, *B.* 23, 2704).

Properties.—Triclinic plates, v. sol. hot water, alcohol, and ether. Smells like benzoic acid. Volatile with steam. Not attacked by sodium-amalgam. Forms with isovaleric acid the double salts $\text{CaA}'(\text{C}_8\text{H}_{13}\text{O}_2)_4\text{aq}$ and $\text{AgA}'\text{C}_8\text{H}_{13}\text{O}_2$.

Reactions.—1. Yields acetic aldehyde and acid on oxidation with KMnO_4 (Beilstein & Wiegand, *B.* 17, 2261; Kondakoff, *J. R.* 20, 523).—2. *Potash-fusion* gives propionic and acetic acids.—3. Fuming HI forms an iodo-valeric acid [87°] (Schmidt, *B.* 12, 252).—4. HI and P yield $\text{CetMeH.CO}_2\text{H}$.—5. *Bromine* forms $\text{C}_8\text{H}_7\text{Br}_2\text{O}_2$ [88°] (Pückert, *A.* 250, 240; Wislizenus, *A.* 272, 21; 274, 99).—6. HOCl forms a mixture of $\text{CH}_3\text{CH}(\text{OH})\text{COClMe.CO}_2\text{H}$ [112°] and $\text{CH}_3\text{CHCl.CMe}(\text{OH})\text{CO}_2\text{H}$ [75°] (Melikoff, *B.* [2] 47, 166).

Salts.— KA' .— CaA' , 3aq. S. (of CaA') 6.4 at 17°.— BaA' , 4aq. S. (of BaA') 18.5 at 16°.— AgA' .

Ethyl ether EtA' . (155°). S.G. 2.942.

Isoamyl ether $\text{C}_8\text{H}_{13}\text{A}'$. (205°).

Reference.—*Chloro-tiglic acid*.

TIGLIC ALDEHYDE $\text{C}_8\text{H}_{12}\text{O}$. *Guaiol*. (118°). V.D. 2.92. Formed by distillation of gum guaiacum (Deville, *C. R.* 17, 1143; 19, 184; Völckel, *A.* 89, 846; Herzig, *M.* 3, 118). Formed also by heating acetic aldehyde (1 mol.) with propionic aldehyde (1 mol.) and aqueous (28 p.c.) NaOAc for 30 hours at 100° (Lieben & Zeisel, *M.* 7, 53). Pungent oil, miscible with alcohol and ether. Oxidised by air to tiglic acid. Alkaline sodium nitroprusside gives a violet-red colour destroyed by HOAc (Von Bitto, *A.* 267, 376). Br. forms di-bromo-valeric aldehyde. Iron and dilute (50 p.c.) acetic acid reduce it to valeric aldehyde (91°), an inactive amyl alcohol $\text{CHMeEt.CH}_2\text{OH}$ (129°) and tiglic alcohol $\text{C}_8\text{H}_{13}\text{O}$ (c. 130°). Reacts with phenyl-hydrazine, and combines with NaHSO_4 . CrO_3 forms acetic acid (Gilm, *A.* 106, 379). Aqueous SO_2 at 0° forms oxy-pentane disulphonic acid (Haymann, *M.* 9, 1055).

TIGLYL ALCOHOL *v.* PENTENYL ALCOHOL.

TIN Sn. At. w. 118.8 (*v. infra*). Mol. w. not known with certainty (*v. infra*). Melts at 231.68° (Callendar & Griffiths, *C. N.* 63, 1); for other data, giving m.p. from 220° to 235°, *v.* Carnelley's *Melting and Boiling-point Tables* (2, 12). Boils between the m.p.s of Ni and Fe, *i.e.* between 1450° and 1600° (Carnelley & Williams, *C. J.* 35, 566). S.G. c. 7.3 (determinations vary from c. 7.0 to c. 7.5) (*v.* Clarke's *Table of Specific Gravities* [2nd ed.] 5). The so-called allotropic variety of tin seems to have S.G. from 5.8 to 6.1 (*v.* Schertel, *J. pr.* [2] 19, 322). S.H. (0°–100°) .0559; so-called allotropic tin has S.H. .0545 (0°–100°) (Bunsen, *P.* 141, 1); S.H. liquid tin (250°–350°) = .0687 (Person, *A. Ch.* [8] 24, 129). C.E. (linear, 0°–100°) .00002296 (Matthiessen,

Pr. 15, 220; v. also Kopp, A. 81, 1; Fizeau, C. R. 68, 1125). T.O. 15.2 (Ag=100) (Wiedemann, P. M. [4] 19, 243). E.C. (Hg at 0°—1) at 15° = 8.823 (Kirchoff a. Hausemann, W. 18, 406); at 0° = 8.726, at 100° = 6.091 (Lorenz, W. 18, 422). Heat of fusion (for 1 kilo. tin) = 14,252 (Person, A. Ch. [8] 24, 129). For spectrum of tin v. Thalén (A. Ch. [4] 18, 237); Salet (C. J. [2] 9, 1147); also Hartley a. Adeney (T. 1884 [i.] 113).

Historical.—Tin was known long before the Christian era. Pliny distinguished *plumbum album* or *candidum* from *plumbum nigrum*; in the fourth century A.D. the former of these substances began to be called *stannum*, from which word the symbol Sn is derived.

Occurrence.—Tin has been found in Siberia and in South Australia. *Tinstone* or *cassiterite*, consisting essentially of SnO_2 , is found in considerable quantities, both in veins and in alluvial deposits, in many parts of the world. *Tin pyrites*, containing SnS , with Cu_2S , FeS , and ZnS , is found in small quantities in various tin veins. Small quantities of SnO_2 occur in various *lithiamicas* (Sandberger, J. M. 1878, 291, 657). According to Lookyer (Pr. 27, 279), there are indications of the occurrence of tin in the sun.

Formation.—1. By ppn. from solution of SnCl_4 in HClAq by tin; or by tin and iron simultaneously, with a little Fe_2O_3 to neutralise excess of acid (Schultze, B. 28, 974).—2. By electrolysis of SnCl_4 in dilute HClAq .—3. By reduction of SnO_2 by heating with C.

Preparation.—*Tinstone* is cleansed by agitation with water; it is then sorted, stamped or rolled to a certain fineness, and washed. The washed ore is calcined in reverberatory calciners to remove sulphur from the sulphides of Fe that are present in most tin ores; the calcined ore is exposed to the air for some days to insure the oxidation of any sulphides that remain in the ore to sulphates, and it is then washed in water, whereby sulphates of Fe, Cu, &c., dissolve and the tin oxide sinks to the bottom of the vessels. The tin oxide is then separated into lighter and heavier parts by agitation with water; the heavier parts are mixed with charcoal or anthracite, some lime or fluorspar is added as a flux, and the mixture is smelted in a reverberatory furnace. The product of the smelting is purified by melting, when the tin runs off, leaving the less fusible foreign metals behind; this purified tin is again melted, the molten mass is stirred with billets of green wood for some hours, and is then allowed to partially solidify by cooling, when the metal separates into different strata, which are ladled into moulds: the upper stratum is the purest and the undermost is the least pure. Sometimes the smelting is conducted in a blast furnace. For details v. TIN in DICTIONARY OF APPLIED CHEMISTRY, vol. iii. p. 834.

Commercial tin generally contains small quantities of As, Cu, Fe, and Pb, and occasionally traces of Sb, Bi, Mn, Mo, W, and Zn. To prepare pure tin, the purest commercial metal is granulated and dissolved in conc. HClAq ; a little water is very slowly poured into the liquid so as to form two layers, and a plate of tin is placed in the liquid so that part of it is in the upper (less conc.) and part in the under (more conc.) layer. A slight electric current is thus produced,

and crystals of pure tin are deposited on the plate (Hiller, A. 85, 258).

Pure tin was prepared by Bongartz a. Classen (B. 21, 2903) by heating the purest commercial tin (Banca tin) in dry Cl and so forming SnCl_4 , distilling fractionally, and collecting that which passed over at 120°, adding to the SnCl_4 about four times its volume of water, and then crystallised Na_2S until the pp. of SnS , that formed was dissolved, then adding NaOHAq about equal to half the quantity of Na_2S used, allowing to stand for some days, drawing off the clear, almost perfectly colourless liquid into a Pt basin, and passing an electric current through this alkaline liquid, washing the ppd. tin with water, then with absolute alcohol, and drying at 100°. The current was arranged so that it produced c. 2 to 3 c.c. detonating gas per minute from water; c. 2 to 3 g. tin were obtained in 24 hours.

Properties.—Pure tin is a silver-white metal; the commercial metal generally has a slightly yellowish tinge. It is unchanged in pure air; but it tarnishes in the air of large towns from formation of a film of sulphide. Tin is one of the least tenacious metals; a wire 1.6 mm. diameter breaks with a weight of c. 14 kilos. Tin may be hammered into plates c. .0254 mm. thick; the malleability varies much with temperature, at 200° the metal is so brittle that it crumbles when hammered. Tin readily crystallises; by fusing, allowing to cool partially, and pouring out the still fluid metal, fair-sized crystals are obtained. Crystals are formed by depositing tin by electrolysis. Stolba (J. 1873, 282) covers the outside of a Pt basin, all except a small portion, with wax, places the unwaxed surface of the basin on a plate of amalgamated zinc in a larger porcelain basin, fills the Pt basin with a dilute and not very acid solution of SnCl_4 , and the porcelain basin with water containing c. $\frac{1}{3}$ part of HClAq ; crystals of tin deposit on the bottom of the Pt basin. The forms of the crystals of tin are probably rhombic and quadratic (von Foullon, J. M. 1885 (11) Ref. 266). According to Frankenheim (P. 40, 456), the crystals belong to the regular system; Miller (B. J. 24, 193) obtained quadratic prisms by separating tin by electrolysis. If a piece of tin is brushed over with warm, dilute *agua regia*, or with a mixture of warm dilute $\text{H}_2\text{SO}_4\text{Aq}$ and HNO_3Aq , the surface becomes covered with a fretwork of crystals, from the facets of which light is unequally reflected, and the surface appears like watered silk. When a bar of tin is bent a crackling sound may be heard due to the crystals in the inner parts of the bar breaking against one another. When warmed, tin has a characteristic smell.

By exposure for some time to a very low temperature (c. -89°) tin crumbles to a grey powder (v. Fritzsche, B. 2, 112, 540); S.G. c. 5.8 to 6.1 (v. Schertel, J. pr. [2] 19, 329). Tin which had been kept for 800 to 400 years was found by Schertel (l.c.) to have become reddish-grey, and so brittle that it was crushed by pressure between the finger-nails; by immersion in boiling water the metal became more coherent and lighter in colour, and the S.G. increased to 7.8 (cf. Oudemans, P. M. [5] 4, 470).

Tin remains lustrous in pure air at the ordinary temperature, and also in water; a

greyish-white film of SnO_2 forms on the surface of tin kept molten in the air; when heated to whiteness in air the metal burns brightly to SnO_2 . Tin dissolves in HClAq , forming SnCl_2 solution; dilute $\text{H}_2\text{SO}_4\text{Aq}$ has only a slight action, conc. hot H_2SO_4 produces SnSO_4 and SO_2 ; dilute HNO_3Aq dissolves tin, with formation of $\text{Sn}(\text{NO}_3)_2\text{Aq}$ and $\text{NH}_4\text{NO}_3\text{Aq}$, conc. HNO_3 transforms the metal into SnO_2 . Tin dissolves in hot conc. NaOHAq , forming Na_2SnO_3 solution and giving off H .

When haloid compounds of tin are volatilised in a stream of H and the gas is ignited, the flame shows two cones; the inner cone is blue with SnCl_2 , green with SnBr_2 , and yellow with SnI_2 , and gives a continuous spectrum; the outer cone is carmine-red, and gives a spectrum with two characteristic lines (Salet, *C. J.* [2] 9, 1147).

Tin is metallic physically, and in most of its chemical relations. The oxide SnO_2 interacts towards several acids as a basic oxide, forming salts SnX_2 ($\text{X} = \text{SO}_4$, &c.); but with conc. KOH or NaOHAq this oxide reacts as an acidic oxide, forming salts M_2SnO_3 . Tin is the third member of the odd-series family of Group IV. in the periodic classification of the elements; it is closely allied to Ge and Pb , and less closely to Si ; it shows very marked analogies with Ti , Zr , Ce , and Th , which (with C) form the even-series family of Group IV. For details of the chemical relations of tin v. **TIN GROUP OF ELEMENTS**, this vol. p. 735.

The atom of tin is divalent in the gaseous molecule SnCl_2 , and tetravalent in the gaseous molecule SnCl_4 .

Supposed allotropic form of tin. The grey brittle powder formed by the action of great cold on tin, and also found in some very old specimens of the metal, is sometimes regarded as an allotropic variety of tin (v. *supra*). All the specimens of tin, however, which have been observed to undergo this change have contained small quantities of impurities; until the change has been effected with pure tin, and has been proved to occur without any change of mass, the existence of an allotropic variety of tin cannot be said to be established. According to von Foulton (*J. M.* 1885 [1] *Ref.* 266) there are three varieties of tin: (1) rhombic, S.G. 6.52 to 6.56; (2) quadratic, S.G. 7.196; (3) grey brittle tin, S.G. 5.781 to 5.809.

Atomic weight of tin. The at. w. has been determined (1) by oxidising Sn to SnO_2 by HNO_3 (Gay-Lussac, *A. Ch.* [2] 80, 163 [1812]; Berzelius, *P.* 8, 184 [1812]; Mulder, *A.* 72, 212 [1849]; Vlaanderen, *B. J.* 1858. 183 [1858]; Dumas, *A. Ch.* [3] 55, 154 [1859]; van der Plaats, *C. R.* 100, 52 [1885]; Bongartz a. Classen, *B.* 21, 2900 [1888]); (2) by ppg. Cl from SnCl_2 by AgNO_3Aq (Dumas, *A. Ch.* [3] 55, 156 [1859]); (3) by electrolysis $\text{SnCl}_2 \cdot 2\text{NH}_4\text{Cl}$ and $\text{SnCl}_2 \cdot 2\text{KCl}$ (B. a. C., *L.c.* [1888]); (4) by electrolysis SnBr_2 (B. a. C., *L.c.*); (5) by reducing SnO_2 in H . (v. d. P., *L.c.* [1885]); (6) by determining S.H. of Sn (Bunsen, *P.* 141, 1 [1870]); (7) by determining V.D. of, and analysing, SnCl_2 and SnCl_4 . The older determinations gave values from 115.9 to 117.8. The results of the determinations of B. a. C. are summarised by them (*L.c.*, p. 2909) as follows:—

Number of experiments	Method	At. weight	Diff. between min. and max. found
11	oxidation of Sn to SnO_2	118.7606	.459
16	electrolysis of $\text{SnCl}_2 \cdot 2\text{NH}_4\text{Cl}$	118.8098	.228
10	electrolysis of $\text{SnCl}_2 \cdot 2\text{KCl}$	118.7975	.163
10	electrolysis of SnBr_2	118.7809	.144

B. a. C. regard the second and third methods as the most trustworthy; in the oxidation of Sn to SnO_2 , the Pt vessel was also slightly acted on, and there was the possibility of a very small loss in dissolving SnBr_2 in the last method. The mean of the results obtained by the electrolysis of the two double chlorides is 118.8 ($O = 15.96$).

Molecular weight of tin. As the V.D. of tin has not been determined the molecular weight is not known. Ramsay determined the depression of the vapour pressure of Hg caused by dissolving tin therein; assuming that equal volumes of dilute solutions contain equal numbers of molecules of the dissolved bodies, and that the mol. w. of liquid Hg is 200, the results obtained by B. gave the mol. w. of tin as 117.4 in one experiment and 149.5° in another.

Reactions and Combinations.—1. When tin is heated in air or oxygen, a film is formed on the surface, containing both SnO and SnO_2 ; when heated to whiteness tin burns brightly, forming SnO_2 (v. Emich, *M.* 14, 845).—2. Heated in chlorine, bromine, or iodine, the compounds SnX_2 and SnX_4 are formed, according to whether there is excess of tin or halogen.—3. Tin combines with sulphur, and with selenium, to form SnS and SnSe , when heated with these elements.—4. Tin probably combines with phosphorus when heated in vapour of that element.—5. Tin forms alloys with many metals (v. **TIN, ALLOYS** or, p. 720).—6. Water is decomposed by tin at a full red heat with formation of SnO and H_2 .—7. *Sulphydic acid* has a slight action on tin, in moist air, forming a film of SnS .—8. *Hydrochloric acid* dissolves the metal, forming solution of SnCl_2 and giving off H ; the reaction proceeds more rapidly with warm conc. HClAq .—9. *Pure conc. nitric acid*, S.G. c. 1.56, has no action on tin. When the acid is diluted the products of the reaction vary with the concentration and the temperature; according to Walker (*C. J.* 63, 845), both $\text{Sn}(\text{NO}_2)_2$ and $\text{Sn}(\text{NO}_3)_2$ are formed, the quantity of $\text{Sn}(\text{NO}_3)_2$ increasing as concentration increases at a fixed temperature; with very dilute acid an increase of temperature causes only a slight increase in the quantity of the stannic salt, but the effect of temperature is very marked with more conc. acid; the proportion of stannous to stannic salt formed is only slightly affected by changing the relative masses of tin and acid; when a fairly conc. solution of tin in HNO_3Aq is heated, hydrated stannic nitrates, varying in composition, are deposited (v. also Montemartini, *G.* 22, 384, 397, 426; abstract in *C. J.* 62, 1402; v. also Hay, *C. N.* 23, 298; Scott, *C. N.* 23, 323). Pure

HNO_3 , diluted sufficiently to start the reaction produces chiefly $\text{SnO}_2 \cdot x\text{H}_2\text{O}$ (*v. Hydrated stannic oxide*, under TIN OXIDES and HYDRATED OXIDES, p. 725). When tin dissolves in HNO_3Aq , NH_4NO_3 is formed; the gases evolved are NO , N_2O , and N (*v. Ackworth a. Armstrong, C. J. 82, 84*).—10. *A mixture of nitric and sulphuric acids, or nitric and hydrochloric acids*, produces NH_4OH along with NH_3 (Divers, *C. J. 43, 443*; D. a. Shimidzu, *C. J. 47, 597*; *cf. Hydroxylamine*, vol. ii. p. 734). With certain proportions of HNO_3Aq and $\text{H}_2\text{SO}_4\text{Aq}$, Bassett (*C. N. 53, 172*) obtained $\text{Sn}(\text{NO}_3)_2$ in solution, and almost pure N_2O .—11. *Dilute sulphuric acid* reacts slowly when warmed with tin, forming SnSO_4 if the tin is kept in excess, and chiefly $\text{Sn}(\text{SO}_3)_2$ if the acid is in excess, and giving off H_2 . *Conc. sulphuric acid* reacts to form SnSO_4 , or $\text{Sn}(\text{SO}_3)_2$, according to the proportion of tin to acid, and evolves H_2S or SO_2 , or both, according to the concentration of the acid and the temperature; with pure hot H_2SO_4 , SO_2 is given off, and S separates (*v. Calvert a. Johnson, C. J. [2] 4, 435*; also Pattison Muir a. Robbs, *C. N. 45, 69*).—12. *Aqua regia* dissolves tin, forming SnCl_4 .—13. Tin reacts with *mercuric chloride and bromide*, when heated with these compounds, forming SnCl_2 , or SnBr_2 , and Hg .—14. With *sulphurous chloride*, SnCl_2 is formed, with production of much heat (Wöhler, *A. 73, 374*).—15. Tin dissolves in warm conc. *caustic potash, or soda*, solution, forming M_2SnO_3 , and giving off H_2 .—16. Fusion with *nitre* forms K_2SnO_3 .

Detection and Estimation.— H_2S ppts. dark brown SnS from slightly acidified solutions of stannous salts; the pp. is soluble in warm yellow ammonium sulphide, forming $(\text{NH}_4)_2\text{SnS}_2\text{Aq}$, from which acids ppt. yellow SnS_2 . AuCl_3Aq produces a purple pp., a compound of Sn , Au , and O (*v. Purple of Cassius*, under TIN OXIDES and HYDRATED OXIDES, p. 727). H_2S ppts. yellow SnS_2 from acidified solutions of stannic salts; the ppt. dissolves in warm yellow ammonium sulphide, and acids re-ppt. SnS_2 from this solution. Tin is generally estimated as SnO_2 .

Tin, alloys of. Tin forms alloys with many metals. For a general account of the properties of different classes of tin alloys, *v. DICTIONARY OF APPLIED CHEMISTRY*, vol. iii. p. 837. For alloys of tin with *antimony*, *v. Karmarsch (D. P. J. 123, 267)*; Kestner (*Kast. Archiv*, 19, 424); Johnson (*Chem. Gazette*, 1855, 180); Chaudet (*A. Ch. [2] 3, 376*); with *bismuth and lead*, and with *bismuth, cadmium and lead*, *v. vol. i. p. 511*; with *cadmium*, *v. vol. i. p. 655*; with *cadmium and gold*, *v. Heycock a. Neville (C. J. 59, 936)*; with *copper*, *v. vol. ii. p. 254* (also *DICTIONARY OF APPLIED CHEMISTRY*, vol. iii. p. 838); with *copper and lead*, *v. vol. iii. p. 125* (also French, *S. C. I. 8, 36*); with *iridium, platinum, and rhodium*, *v. Deville a. Debray (C. R. 81, 889)*; with *iron*, *v. vol. iii. p. 53* (also Headen, *Am. S. [3] 44, 464*); with *gold*, *v. Laurie (P. M. [5] 33, 94)*; with *lead*, *v. vol. iii. p. 125*; with *lead and zinc*, *v. vol. iii. p. 125* (also Wright a. Thompson, *Pr. 45, 461*; 48, 25); with *mercury*, *v. infra*; with *platinum*, *v. vol. iv. p. 288*; with *silver*, *v. W. a. T. (Pr. 48, 25)*; with *sodium*, *v. Bailey (C. N. 65, 18)*. Tin alloys with *zinc* in all proportions; the alloys are harder than tin, but softer than zinc; they are less

malleable than tin. Many varieties of bronze are alloys of tin with *zinc and copper* (*v. Rudberg, P. 18, 240*). *Amalgams of tin* are readily formed by immersing tin in Hg ; the action is more rapid if the Hg is warmed (*v. Böttger, J. pr. 1, 305*; Joule, *Chem. Gazette*, 1850, 339, also *C. J. 16, 384*; Kupffer, *A. Ch. [2] 40, 293*).

Tin, bromides of. Tin combines with Br to form two compounds, SnBr_2 and SnBr_4 . The V.D. of the latter has been determined, and the formula SnBr_4 is molecular; from the analogy of the chlorides it is probable that the formula SnBr_2 is molecular also. Watts a. Bell (*C. J. 33, 442*) obtained both SnBr_2 and SnBr_4 by heating SnO_2 in Br vapour mixed with CO .

STANNOUS BROMIDE SnBr_2 . (Dibromide of tin.) Obtained by Balard (*A. Ch. [2] 32, 337*); more fully examined by Rayman a. Preis (*A. 223, 323*). Prepared by heating tin in HBr gas, allowing the oily liquid so obtained to cool, dissolving the crystals that form in dilute HBrAq , and purifying the solid that separates by distilling it in a stream of N . A crystalline, slightly yellow, transparent solid; melts at 215.5° to a transparent liquid, which solidifies at 215° . S.G. 5.117 at 17° . Carnelley a. Williams (*C. J. 35, 563*) say that SnBr_2 boils between 617° and 634° . Partly decomposed by water, with separation of an oxybromide of tin (*R. a. P., l.c.*). By crystallising a solution of tin in warm conc. HBrAq , *R. a. P. (l.c.)* obtained the hydrate $\text{SnBr}_2 \cdot x\text{H}_2\text{O}$ ($x=1$ or 2), in colourless needles. By cooling a mixture of NH_4Cl and solution of tin in warm conc. HBrAq , the compound $\text{SnBr}_2 \cdot 2\text{NH}_4\text{Cl} \cdot \text{H}_2\text{O}$ was obtained in large rhombic, porcelain-like crystals (*R. a. P., l.c.*).

STANNIC BROMIDE SnBr_4 . (Tetrabromide of tin.) Mol. w. 437.8. Melts at 30° (Carnelley a. O'Shea, *C. J. 83, 65*), at 33° (Rayman a. Preis, *A. 223, 323*). Boils at c. 201° (*C. a. O'S., l.c.*), at 203.3° (*R. a. P., l.c.*). S.G. 3.349 (*R. a. P., l.c.*). V.D. at 228° – $260^\circ = 227.230$ (*C. a. O'S., l.c.*). Prepared by passing vapour of Br over melted tin in a tube shaped thus 

the tin being at *b* and the Br at *a*. The tin burns in the Br vapour; the product is distilled backwards and forwards from *b* to *c* until the distillate is quite colourless. On cooling the liquid solidifies to colourless crystals of SnBr_4 (*C. a. O'S., l.c.*). *R. a. P. (l.c.)* prepared SnBr_4 by heating tin with Br , and crystallising from SnCl_4 or SnBr_4Cl . SnBr_4 forms white crystals, which are slowly decomposed in the air; according to *R. a. P. (l.c.)* the crystals deliquesce to a clear liquid, which when placed over H_2SO_4 deposits crystals of the hydrate $\text{SnBr}_4 \cdot 4\text{H}_2\text{O}$. SnBr_4 is soluble in cold water; after some hours $\text{SnO}_2 \cdot x\text{H}_2\text{O}$ is deposited; boiling hastens this change; addition of HNO_3Aq to hot SnBr_4Aq ppts. all the tin as $\text{SnO}_2 \cdot x\text{H}_2\text{O}$, with evolution of a little Br (*C. a. O'S., l.c.*). *R. a. P. (l.c.)* found that SnBr_4 absorbs NH_3 ; on heating some NH_3 was given off, and a yellow sublimate of $\text{SnBr}_2 \cdot 2\text{NH}_3$ was obtained. According to Nickles (*C. R. 59, 869*), SnBr_4 combines with ether to form $\text{SnBr}_4 \cdot \text{Et}_2\text{O}$.

Stannibromhydric acid $\text{H}_2\text{SnBr}_2 \cdot x\text{H}_2\text{O}$. (Bromostannic acid. Hydrobromostannic acid.) This compound was obtained by Seubert (*B. 20, 194*) by adding 74.1 parts HBrAq (50 p.c. HBr)

to 100 parts SnBr_2 (i.e. in the ratio $2\text{HBr}:\text{SnBr}_2$). A yellow liquid was formed which solidified after a time to a mass of yellow, needle-shaped crystals; the small quantity of mother-liquor was removed by melting and allowing to solidify partially. It is doubtful whether the acid crystallises with 7 or $9\text{H}_2\text{O}$. The acid forms amber-yellow needles, probably triclinic; it is very deliquescent; fumes in air, giving off HBr . By adding Na_2CO_3 to $\text{H}_2\text{SnBr}_2\text{Aq}$, and allowing to evaporate, Seubert (*l.c.*) obtained *sodium stannibromide*, $\text{Na}_2\text{SnBr}_6 \cdot 6\text{H}_2\text{O}$, in yellow needles. Several other stannibromides are described by Rayman a. Preis (A. 223, 323); their composition is $\text{MSnBr}_x \cdot x\text{H}_2\text{O}$, where $\text{M} = (\text{NH}_4)_2, \text{Ba}, \text{Ca}, \text{Fe}, \text{Mg}, \text{Mn}, \text{Ni}, \text{Na}, \text{Sr}$, and x is 6, 8, or 10.

Tin, bromochlorides of. Rayman a. Preis (A. 223, 323) obtained a compound to which they gave the formula SnBr_2Cl by heating tin in Br that contained some Cl , and repeatedly distilling. The compound is a liquid boiling between 181° and 190° . It dissolves SnBr_2 , which crystallises unchanged. By adding Br to excess of SnCl_2 Ladenburg (*A. Supplbd.* 8, 60) obtained indications of the formation of bromochlorides, probably SnBr_2Cl and SnBrCl_2 .

Tin, chlorides of. Tin and Cl combine to form two compounds, SnCl_2 and SnCl_4 . Both formulæ are molecular.

STANNOUS CHLORIDE SnCl_2 . (*Dichloride of tin. Tin-salt.*) Mol. w. 189.54; perhaps 379.08 ($=\text{SnCl}_2$) in the liquid state (*v. infra*). Melts at 249.3° (Carnelley a. Williams, *C. J.* 35, 63). Boils between 617° and 628° (C. a. W., *l.c.*); at 606° (Biltz a. Meyer, *Z. P. C.* 2, 184). V.D. *v. infra*. H.F. (SnCl_2) = 80,790; [SnCl_2Aq] = 81,140; [$\text{SnCl}_2 \cdot 2\text{H}_2\text{O}$] = 86,520 (*Th.* 3, 327).

Preparation.—1. By heating a mixture of equal parts tin filings and HgCl_2 ; Hg sublimes and leaves SnCl_2 .—2. By heating tin in HCl gas.—3. By dissolving tin in warm, fairly conc. HClAq , evaporating to the crystallising point, drying the crystals of $\text{SnCl}_2 \cdot 2\text{H}_2\text{O}$ that separate, heating them in a capacious crucible so long as gases are given off, pouring the liquid into a small crucible, pounding when cold, and distilling from a retort; the first portions of the distillate are said to be pure SnCl_2 (Capitaine, *J. Ph.* 25, 552).

Properties.—A semi-transparent, white solid; melts at $c. 250^\circ$ and boils at incipient redness (*v. supra*). Heated to bright redness, out of air, some SnCl_4 is given off, then SnCl_2 . Heated in air gives SnCl_2 and SnO_2 . SnCl_2 dissolves in a little water; the solution is decomposed by much dilution, with separation of a hydrated oxychloride $\text{SnCl}_2 \cdot \text{SnO} \cdot 2\text{H}_2\text{O}$. According to Michael a. Kraft (*A. Ch.* [3] 41, 471), 1,000 c.c. saturated SnCl_2Aq contains, at 15° , 1,333 g. SnCl_2 and 494 g. water, and the S.G. is 1.827. Gerlach (*D. P. J.* 186, 181) gives the following data for a solution of the hydrate $\text{SnCl}_2 \cdot 2\text{H}_2\text{O}$:—

P.c.	S.G.	P.c.	S.G.
$\text{SnCl}_2 \cdot 2\text{H}_2\text{O}$	of solution	$\text{SnCl}_2 \cdot 2\text{H}_2\text{O}$	of solution
5	1.0381	45	1.3850

40	1.3298		

VOL. IV.

An aqueous solution of SnCl_2 generally becomes turbid from ppn. of Sn_2OCl_2 ; digestion with tin and a little HClAq dissolves the pp.; addition of tartaric acid, or NH_4Cl , stops the solution from becoming turbid, the former by dissolving the oxychloride, the latter by forming a double salt $\text{SnCl}_2 \cdot 2\text{NH}_4\text{Cl}$, which is very soluble in water.

Mallet (*C. J.* 35, 524) obtained a semi-transparent, jelly-like solid from an aqueous solution of SnCl_2 which had stood in a loosely closed bottle for a year or two; the solid dried to a substance like gum arabic; it reddened litmus; the composition of the substance was $\text{SnO}_2 \cdot \text{HCl}$. Mallet writes the formula as $\text{SnO} \cdot \text{OH} \cdot \text{Cl}$, and suggests the name *chlor-stannic acid*.

Molecular weight of stannous chloride. The V.D. of the gas obtained by heating SnCl_2 has been determined repeatedly. The following table presents the results:—

Calculated for SnCl_2	Calculated for Sn_2Cl_4	Temp., and Observers
94.7	189.4	
	103.7 ? temp.	Rieth, <i>B.</i> 3, 668 [1870].

	119.5	" 760° P. C. 2, 184
	111.4	" 790° [1888].
	102.7	" 1113°

From their determinations, Biltz a. Meyer concluded that molecules of the composition Sn_2Cl_4 do not exist in the gaseous state, and that the mol. w. of the gas comes to a constant value, corresponding with the formula SnCl_2 , only at a temperature very much above the b.p. of the liquid (SnCl_2 boils at 606°). In some of the earlier determinations at $c. 800^\circ$ partial decomposition occurred, with production of Cl . The results, taken as a whole, seem to be explained by assuming that the molecules of the liquid, near to the b.p., have the composition Sn_2Cl_4 , that some of these are dissociated to 2SnCl_2 at $c. 30^\circ$ above the b.p., and that this process of dissociation continues slowly, and is not completed at even 500° above the b.p.

Reactions.—1. Heated strongly in air, SnCl_2 is given off, and SnO_2 remains. Heated to its b.p. in a retort, SnCl_2 and SnCl_4 distil, and the oxychloride Sn_2OCl_2 remains (Capitaine, *J. Ph.* 25, 552).—2. When sulphur is added to molten SnCl_2 , the products are SnCl_4 and SnS ; with selenium the products are SnCl_4 and SnSe (Schneider, *P.* 127, 624).—3. Many salts are reduced by SnCl_2Aq , either to lower salts or to metals. Au, Hg, and Ag are ppd. from solutions of their salts; ferric and manganic salts are reduced to ferrous and manganous salts; CuCl_2Aq to Cu_2Cl_2 .—4. The higher oxides of Bi, Cr, Pb, Mo, W, &c., are reduced to the lower oxides of these metals.—5. Arsenious oxide is reduced to As by a considerable excess of SnCl_2Aq .—6. According to Böttger (*Polytech. Notizbl.* 35, 96), a mixture of 2 pts. SnCl_2 rubbed with 1 pt.

3 A

potassium chlorate gets hot, and produces an oxychloride of tin, KClO_2 , oxide of chlorine, and H_2O . For reactions with water *v. supra*, Properties; also *infra*, Combinations, No. 1.

Combinations.—1. With water to form the hydrate $\text{SnCl}_4 \cdot 2\text{H}_2\text{O}$. This compound is prepared by dissolving tin in warm conc. HClAq and evaporating to the crystallising point, in contact with tin to prevent formation of SnCl_4 . $\text{SnCl}_4 \cdot 2\text{H}_2\text{O}$, commonly known by the name of *tin-salt*, forms large white, monoclinic crystals (Marignac, *J.* 1856, 394); melts at c. 37.7° ; S.G. 2.71 at 15.5° (solid), 2.588 at 37.7° (liquid) (Penny, *C. J.* 4, 239). H.F. $[\text{SnCl}_4 \cdot 2\text{H}_2\text{O}] = 86,520$ (*Th.* 3, 327). When gradually heated to 100° , most of the water is removed; when rapidly heated, H_2O and HCl are given off and Sn_2OCl_2 remains, which gives off SnCl_4 when more strongly heated. $\text{SnCl}_4 \cdot 2\text{H}_2\text{O}$ decomposes slowly on exposure to the air, forming Sn_2OCl_2 and SnCl_4 .—2. With ammonia, forming $\text{SnCl}_4 \cdot \text{NH}_3$.—3. According to Engel (*C. R.* 106, 1398), a compound of SnCl_4 with hydrogen chloride is formed by passing HCl gas over $\text{SnCl}_4 \cdot 2\text{H}_2\text{O}$ at 0° ; the liquid thus formed solidifies at 27° , forming crystals of $\text{SnCl}_4 \cdot \text{HCl} \cdot 3\text{H}_2\text{O}$, which melt at 40° .—4. With chlorides of the alkali and alkaline earth metals, to form $\text{MCl}_x \cdot \text{SnCl}_4 \cdot x\text{H}_2\text{O}$, where $\text{M} = (\text{NH}_4)_2, \text{K}_2, \text{Ba}$, or Sr (*v. Marignac, C. R.* 55, 650; Rammelsberg, *Krystall. Chemie*, 211; Richardson, *Am.* 14, 89). Poggiale (*C. R.* 20, 1180) described a salt $\text{SnCl}_4 \cdot 4\text{NH}_4\text{Cl} \cdot 3\text{H}_2\text{O}$. Richardson (*l.c.*) obtained $\text{SnCl}_4 \cdot \text{KCl} \cdot \text{H}_2\text{O}$ as well as $\text{SnCl}_4 \cdot 2\text{KCl} \cdot 2\text{H}_2\text{O}$. These double salts are perhaps best regarded as *stannochlorides*, derived from the acid HSnCl_4 (*v. Combinations*, No. 3) and the hypothetical acid H_2SnCl_4 .

STANNIC CHLORIDE SnCl_4 . (*Tetrachloride of tin*.) Mol. w. 260.28. Boils at 113.9° at 760 mm. (Thorpe, *C. J.* 37, 372); at 114.1° at 760 mm. (Young, *C. J.* 59, 912). Solidifies at -33° (Besson, *C. R.* 109, 940). S.G. $^\circ$ 2.27875; 1.97813 at b.p. (Thorpe, *l.c.*). V.D. 133.1 at 124° (Dumas, *A. Ch.* [2] 33, 385). S.H. 1402 (10° – 15°) (Regnault, *A. Ch.* [3] 9, 332). Heat of vaporisation = 30,530 (gram-units for 1 kilo.) (Andrews, *C. J.* 1, 27). H.F. $[\text{SnCl}_4] = 127,250$; $[\text{SnCl}_4 \cdot \text{Aq}] = 157,170$; $[\text{SnCl}_4 \cdot \text{Cl}_2] = 46,460$; $[\text{SnCl}_4 \cdot \text{Aq}, \text{Cl}_2] = 76,030$ (*Th.* 3, 327). C.E. (cubical, 0° – 100°) .00130244 (Thorpe, *l.c.*). S.V. 131.07 (Thorpe, *l.c.*; for S.V. from 0° to 280° *v. Young, C. J.* 59, 933, 985). For vapour pressures from -10° to 319° *v. Young (l.c., p. 927)*. Critical temperature = 318.7° ; critical pressure = 28080 mm. (*X., l.c., p. 928*).

Formation.—1. By heating tin in excess of Cl_2 .—2. By heating 1 pt. tin filings intimately mixed with 4 or 5 pts. HgCl_2 .—3. By heating a mixture of $\text{Sn}(\text{SO}_4)_2$ and NaCl .—4. By passing vapour of CCl_4 over heated SnO_2 (Watts *a. Bell, C. J.* 33, 442).—5. By adding fuming sulphuric acid to tin, and then passing in HCl gas and distilling (Heumann *a. Köchlin, B.* 15, 416).

Preparation.—Dry Cl_2 is led over tin filings heated in a retort connected with a dry flask, which is kept cold; the distillate is distilled from tin filings, and then repeatedly redistilled in a current of dry CO_2 . A solution of SnCl_4 is obtained by passing Cl_2 into $\text{SnCl}_4 \cdot \text{Aq}$ until no pp. is produced with $\text{HgCl}_2 \cdot \text{Aq}$, or by dis-

solving tin in dilute HClAq containing a little HNO_3 .

Properties.—A thin, mobile, colourless, fuming, very corrosive liquid. Solidifies at -33° to small white crystals (Besson, *C. R.* 109, 940). SnCl_4 dissolves crystalline S, also P, I, Br, CS_2 , &c. (Girardin, *C. R.* 51, 1057). SnCl_4 does not conduct electricity, even at its b.p.; addition of absolute alcohol forms crystals, probably $(\text{SnCl}_4 \cdot 5\text{EtOH})$, which conduct when dissolved; ether behaves similarly to alcohol (Coldridge, *P. M.* [5] 29, 383, 480). SnCl_4 withdraws moisture from the air, probably forming $\text{SnCl}_4 \cdot 3\text{H}_2\text{O}$ (*v. infra, Hydrates of stannic chloride*). SnCl_4 dissolves in water, with production of heat $[\text{SnCl}_4 \cdot \text{Aq}] = 29,920$ (*Th.* 3, 327), and considerable contraction of volume (*v. also Reactions*, No. 1). Gerlach (*D. P. J.* 178, 49) gives the following table:—

Pcntge. SnCl_4	S.G. $\text{SnCl}_4 \cdot \text{Aq}$	Vol. of 100 pts. by wt. of solution; vol. of 100 pts. water = 100	Vol. of mixture of SnCl_4 and water; vol. of sum of constituents = 100
0	1.000	100.00	100.00
10	1.082	92.42	97.82
20	1.174	85.18	95.76

60	1.743	57.37	85.81
70	1.973	50.68	82.63
100	2.234	44.76	100.00

Hydrates of stannic chloride.—Various hydrates have been isolated: (1) $\text{SnCl}_4 \cdot 3\text{H}_2\text{O}$, by exposing SnCl_4 to air (Casselmann, *A.* 83, 272); also by adding 18 pts. water to 260 pts. SnCl_4 , when $\frac{2}{3}$ of the SnCl_4 remains unchanged, and $\frac{1}{3}$ forms the hydrate, which sinks in the excess of SnCl_4 (Gerlach, *D. P. J.* 178, 49); also by dissolving 260 pts. SnCl_4 in 54 pts. water, and letting the solution cool to 60° (*G., l.c.*); (2) $\text{SnCl}_4 \cdot 2\text{H}_2\text{O}$, by keeping the trihydrate *in vacuo* (Scheurer-Kestner, *C. R.* 50, 50); also by drying the pentahydrate over H_2SO_4 (Lewy, *A. Ch.* [3] 16, 303); (3) $\text{SnCl}_4 \cdot 5\text{H}_2\text{O}$, by dissolving SnCl_4 completely in water and evaporating (*G., l.c.; L., l.c.*); (4) $\text{SnCl}_4 \cdot 8\text{H}_2\text{O}$, by strongly cooling dilute $\text{SnCl}_4 \cdot \text{Aq}$ (*G., l.c.*); (5) $\text{SnCl}_4 \cdot 9\text{H}_2\text{O}$, obtained by Nöllner (*Z.* [2] 1, 445) by treating $\text{SnCl}_4 \cdot \text{Aq}$ with *aqua regia*, and exposing the solution to a winter temperature. Gerlach (*l.c.*) gives a table (*v. next page*), showing the S.G. and percentage composition of solutions of the pentahydrate.

Reactions.—1. With water: SnCl_4 dissolves in water (*v. supra*) with production of much heat. Vignon (*C. R.* 108, 1049; 109, 872) found that H_2SnO_3 ppd. from freshly prepared $\text{SnCl}_4 \cdot \text{Aq}$, from $\text{SnCl}_4 \cdot \text{Aq}$ after keeping, and from $\text{SnCl}_4 \cdot \text{Aq}$ after heating, showed markedly different heats of neutralisation by potash. He concluded that $\text{SnCl}_4 \cdot \text{Aq}$ contains HClAq and $\text{H}_2\text{SnO}_3 \cdot \text{Aq}$, and that the H_2SnO_3 in solution gradually polymerises. Dilute $\text{SnCl}_4 \cdot \text{Aq}$ gradually decomposes, giving HClAq and $\text{SnO}_2 \cdot x\text{H}_2\text{O}$ (Casselmann, *A.* 83, 272). Heating in a sealed tube with a little water is said to give SnO_2 .—2. With conc. nitric acid SnCl_4 forms $\text{SnO}_2 \cdot x\text{H}_2\text{O}$.—3. Dry hydrogen sulphide forms white crystals of $\text{SnCl}_4 \cdot 5\text{H}_2\text{S}$, which gives off H_2S and HCl when heated, and

leaves SnS₂ (Coldridge, *P. M.* [5] 29, 383, 480).—4. SnCl₄ dissolves *stannous oxide*, forming SnCl₄ and a solution of SnO₂.H₂O in excess of SnCl₄ (Scheurer-Kestner, *C. R.* 50, 50).

Combinations.—1. With *hydrogen chloride*. By passing dry HCl over SnCl₄.5H₂O, then saturating the liquid so formed with dry HCl at 28°, and cooling to 0°, Engel (*C. R.* 103, 213) obtained white crystalline leaflets of the compound SnCl₄.2HCl.6H₂O, melting at c. 20°, and giving off HCl when more strongly heated. The same compound was prepared by Seubert (*B.* 20, 793) by adding to SnCl₄ such a quantity of conc. HClAq that the ratio of water in the acid was to the SnCl₄ as 6H₂O:SnCl₄ (100 pts. SnCl₄ require 62.15 pts. of 33 p.c. HClAq), and after a little passing in c. 8 pts. dry HCl; the whole then solidified to a crystalline mass, melting at 19.2°. This

compound is best called *stannichlorhydric acid*; it has also been called *chlorostannic acid* (Mallet gave the name *chlor-stannic acid* to SnO.OH.Cl, *v.* STANNOUS CHLORIDE, *Properties*, p. 721), and *hydrochlorostannic acid*. Chassevant (*A. Ch.* [6] 30, 5) has described a compound SnCl₄.HCl.3H₂O.—2. With several *metallic chlorides*. The double salts of SnCl₄ and alkali and alkaline earth chlorides have the composition MSnCl₄.xH₂O, where M = (NH₄), K, Na, Ba, Ca, Mg, or Sr; these salts are best named *stannichlorides* (for details, *v.* Bolley, *A.* 39, 101; Lewy, *J. pr.* 37, 479; Rammelsberg, *Krystall. chemie*; Wittstein, *R. P.* 64, 7; Topsoë, *W. A. B.* 69 [2] 261; Morel, *C. C.* 1891 [1] 492; Chassevant, *A. Ch.* [6] 30, 5). Cleve (*Bl.* [2] 31, 195) obtained double salts of the form xSnCl₄.2MCl₂.xH₂O, where M = Ce, Di, La, or Y, x = 2 and 5, and x had large values (from 18 to 45).—3. With certain *non-metallic chlorides*; the compound SnCl₄.2SnCl₂ is said to be obtained by the interaction of Cl and SnS (H. Rose, *P.* 44, 320; Casselmann, *P.* 42, 517); the compound SnCl₄.PCl₅ was obtained by Casselmann (*l.c.*) by heating a mixture of SnCl₄.2SnCl₂ and PCl₅ in a stream of HCl.—4. With certain *nonmetallic oxychlorides*: (1) SnCl₄.POCl₃, formed by the reaction of POCl₃ and SnCl₄ (Casselmann, *A.* 91, 248; 98, 213); (2) SnCl₄.2SeOCl₂, by combining the constituent compounds (Weber, *B. B.* 1865. 154); (3) SnCl₄.2NOCl, by passing the dry vapour from *aqua regia* over SnCl₄ (Hampe, *A.* 126, 43), also by subliming SnCl₄.N₂O₃ formed by the action of N₂O and NO₂ on SnCl₄ (Weber a. Hampe, *P.* 118, 471).—5. With *hydrogen sulphide* to form SnCl₄.5H₂S; decomposed by heating to SnS₂, H₂S, and HCl (Coldridge, *P. M.* [5] 29, 383).—6. With *hydrogen cyanide*, to form crystals that are decomposed in moist air (Klein, *A.* 74, 85).—7. With *ammonia*, to form SnCl₄.2NH₃ according to H. Rose (*P.* 24, 163), to form SnCl₄.4NH₃ according to Grouvelle a. Persoz (*A. Ch.* [2] 44, 322).—8. With *phosphorus trihydride*, to form 3SnCl₄.2PH₃ (H. Rose, *P.* 24, 159); heated to 100° in CO₂ there are formed HCl and Sn₂P₂Cl₆, according to Mahn (*J. Z.* 5, 160).—9. With certain *nonmetallic oxides*: (1) with SO₂ to form a solid [? composition] (H. Rose, *P.* 44, 320); (2) with NO a compound is formed, according to Kuhlmann (*A.* 39, 319), but no action occurs according to Hampe (*A.* 126, 43); (3) with N₂O₃ to form SnCl₄.N₂O₃, produced by passing NO₂ and N₂O over SnCl₄ (Hampe, *l.c.*).—10. With *ethyl alcohol*, to form SnCl₄.5EtOH (Coldridge, *P. M.* [5] 29, 383, 480).—11. With *amyl alcohol*, to form SnCl₄.2C₅H₁₁(OH) (Bauer a. Klein, *Z.* [2] 4, 870).—12. With *ether*, to form SnCl₄.2Et₂O (Coldridge, *l.c.*).—13. With various *nitriles*, forming crystallisable compounds (Lewy, *C. R.* 21, 371).

Tin, chloropromides of, *v.* TIN BROMOCHLORIDES, p. 721.

Tin, chloro-iodide of; *v.* TIN IODOCHLORIDE, p. 724.

Tin, chlorosulphide of; *v.* TIN THIOCHLORIDE, p. 733).

Tin, ferricyanides of; *v.* vol. ii. p. 340.

Tin, ferrocyanides of; *v.* vol. ii. p. 337.

Tin, fluorides of. Only one fluoride, SnF₄, has been isolated; double salts of stannic fluoride (SnF₄) are known.

STANNOUS FLUORIDE SnF_2 . (*Di-fluoride of tin*.) Formed, in small opaque, lustrous, prisms, by dissolving $\text{SnO} \cdot x\text{H}_2\text{O}$ in HFAq, and evaporating; heated in air it forms the oxyfluoride $\text{SnOF}_2 (= \text{SnF}_2 \cdot \text{SnO}_2)$ (Marignac, *Ann. M.* [5] 15, 221; Fremy, *A. Ch.* [3] 47, 37). By dissolving freshly ppt. $\text{SnO} \cdot x\text{H}_2\text{O}$ in solutions of alkali fluorides acidified by HFAq, Wagner (*B.* 19, 896) obtained *stannofluorides* of the form $x\text{SnF}_2 \cdot 2\text{MF} \cdot y\text{H}_2\text{O}$, where $x = 1$ and 3 , $y = 1$ and 2 , and M was NH_4 , K , and Na .

STANNIC FLUORIDE. This compound has not been isolated; a solution of $\text{SnO}_2 \cdot x\text{H}_2\text{O}$ in HFAq coagulates when heated, but does not yield any definite compound; when evaporated in air HF is given off, and an oxyfluoride, SnOF_2 , is deposited (Marignac, *l.c.*).

Stannifluorides. A series of these salts, $\text{MSnF}_2 \cdot x\text{H}_2\text{O}$, where $\text{M} =$ one atom of a divalent metal or two atoms of a monovalent metal, has been obtained by Marignac (*Ann. M.* [5] 15, 221). The salts are isomorphous with the corresponding silicofluorides and titanifluorides; they are generally obtained by saturating the stannates with HFAq and evaporating, some are formed by double decomposition from the Pb or Ag salt. The following salts have been obtained: $\text{MSnF}_2 \cdot x\text{H}_2\text{O}$; $\text{M} = \text{NH}_4$, Ba , Cd $x = 6$, Ca $x = 2$, Cu $x = 3$, Pb $x = 3$, Li $x = 2$, Mg $x = 6$, Mn $x = 6$, Ni $x = 6$, K $x = 1$, Ag $x = 4$, Na , Sr $x = 2$, Zn $x = 6$.

Tin, haloid compounds of. Tin and the halogens combine to form two series of compounds, SnX_2 and SnX_4 (SnF_4 has not been isolated). The V.D.s of SnCl_2 , SnCl_4 , and SnBr_4 have been determined; it is probable that the simplest formula in every case is molecular. One or two compounds of the forms SnXX' and SnXX_2' are known, where X and X' are different halogens. A few oxyhaloid compounds are known, and probably also one or two thiohaloid compounds. The compounds SnBr_2 and SnCl_2 combine with HBr and HCl respectively, forming acids H_2SnBr_4 and H_2SnCl_4 , from which series of salts, stannibromides and stannichlorides, are derived; stannifluorides are also known. An acid HSnCl_3 has also been isolated, and a few stannochlorides— M^1SnCl_3 and M^2SnCl_4 —are known, as also some stannofluorides.

Tin, hydrosulphide of. The compound SnS_2H_2 , which has probably been isolated, may be called hydrosulphide of tin (v. **TIN, THIOACIDS AND SALTS OF**, p. 733).

Tin, hydroxides of, v. TIN OXIDES AND HYDRATED OXIDES, p. 725; also **TIN OXYACIDS AND SALTS**, p. 727.

Tin, hydroxyl chloride of, $\text{SnO} \cdot \text{OH} \cdot \text{Cl}$, v. Chlor-stannic acid, under **STANNOUS CHLORIDE**, *Properties*, p. 721.

Tin, iodides of. Two compounds are formed by combining tin and I ; they correspond in composition with the two bromides and the two chlorides. The V.D.s of the iodides have not been determined, but the simplest formulae are probably molecular.

STANNOUS IODIDE SnI_2 . (*Di-iodide of tin*.) Formula probably molecular.

Preparation.—1. Tin and I are heated together in the ratio $\text{Sn} : 2\text{I}$ (1 pt. tin to 2.14 pts. I); the brown crystalline solid so formed (a mixture of SnI_2 and SnI_4) is mixed with tin

filings and heated, when orange-red SnI_2 , sublimates, and SnI_4 remains as a red crystalline solid mixed with particles of tin, which are easily separated (Henry, *T.* 1845. 363).—2. Conc. $\text{KI} \cdot \text{Aq}$ is added to warm conc. $\text{SnCl}_4 \cdot \text{Aq}$; the yellow crystalline pp. is dried and melted, out of contact with air, and a red crystalline mass of SnI_2 is formed on cooling (Boullay, *A. Ch.* [2] 34, 372).—3. Tin foil is heated for some hours with fairly conc. HIAq in a sealed tube at 120° – 150° (Wöhler a. Dünhaupt, *A.* 86, 374); SnI_2 separates, on cooling, in shining yellow-red prisms.

Properties and Reactions.—A red, crystalline solid. Melts at 316° (Carnelley a. Williams, *C. J.* 35, 564). Slightly soluble in cold, more soluble in hot, water, without decomposition (Boullay, *l.c.*). According to Personne (*C. R.* 54, 216), SnI_2 is decomposed by a large quantity of water, forming HIAq and several oxyiodides (*q. v.*). SnI_2 is soluble in $\text{SnCl}_4 \cdot \text{Aq}$. When heated out of contact with air, SnI_2 melts without decomposition, but when heated in the air it is decomposed to an oxyiodide, which remains in the vessel, and SnI_4 , which sublimates.

Combinations.—1. With *stannous chloride* to form $\text{SnI}_2 \cdot \text{SnCl}_2$ (v. *Iodochloride*, *infra*).—2. With *stannous oxide* to form several oxyiodides (*q. v.*).—3. With *ammonia*, probably forming $\text{SnI}_2 \cdot 2\text{NH}_3$ (Rammelsberg, *P.* 48, 169).—4. With *alkali iodides* and with *iodides of the alkaline earth metals* to form *stanno-iodides*; these salts have the composition $\text{M}_2\text{SnI}_4 \cdot x\text{H}_2\text{O}$ and $\text{MSnI}_4 \cdot x\text{H}_2\text{O}$, corresponding with the stannochlorides (v. **STANNOUS CHLORIDE**, *Combinations*, p. 722); $\text{M} = \text{NH}_4$, K , Na , also $\frac{1}{2}\text{Ba}$ and $\frac{1}{2}\text{Sr}$. The stanno-iodides are formed by mixing solutions of the constituent salts, or by adding $\text{SnCl}_4 \cdot \text{Aq}$ to excess of the alkaline iodide in solution; the salts must be crystallised from alcohol, as they are decomposed by water, forming stannous oxyiodides (v. Boullay, *l.c.*; Personne, *l.c.*).

STANNIC IODIDE SnI_4 . (*Tetra-iodide of tin*.) Formula probably molecular. This compound is probably formed by heating tin with 4.2 pts. I , and subliming from the product (Henry, *T.* 1845. 363). Schneider (*P.* 127, 624) recommends to add 6 pts. CS_2 to 1 pt. tin filings, and then to add gradually, cooling frequently, 4 pts. I , and to allow the yellow liquid to evaporate.

SnI_4 crystallises in orange-red octahedra; melts at 146° , sublimates at 180° , and boils at 295° (Personne, *C. R.* 54, 216). S.G. 4.696 at 11° (Bödeker, *Die Beziehungen zwischen Dichten u. Zusammensetzung bei festen u. liquiden Stoffen* [Leipzig, 1860]). Solubility in CS_2 at $15^\circ = 145$ (Schneider, *l.c.*); it is also soluble in CHCl_3 , EtOH , Et_2O , and C_2H_4 . Decomposed by water to $\text{SnO}_2 \cdot x\text{H}_2\text{O}$ and HIAq . Combines with ammonia to form $\text{SnI}_4 \cdot x\text{NH}_3$, where $x = 3, 4$, and 6 (Personne, *l.c.*), also $= 8$ (Rammelsberg, *P.* 48, 169). SnI_4 is said not to combine with alkali iodides.

Tin, iodochloride of, $\text{SnI} \cdot \text{Cl}$ ($= \text{SnI}_2 \cdot \text{SnCl}_2$). According to Henry (*T.* 1845. 363) the addition of I to conc. $\text{SnCl}_4 \cdot \text{Aq}$ causes ppn. of SnI_2 , and on evaporating the mother-liquor (which contains SnCl_2 , SnCl_4 , and SnI_4) straw-yellow crystals are deposited that have the composition $\text{SnI}_2 \cdot \text{SnCl}_2$. The crystals are decomposed by water, with separation of SnI_2 .

Tin, iodosulphide of, v. TIN THIO-IODIDE, p. 738.

Tin, oxides and hydrated oxides of. Two oxides have been isolated, SnO and SnO_2 ; various compounds of these oxides with H_2O seem to exist, but their composition readily undergoes change with variation of temperature. Both oxides interact with acids to form corresponding salts, SnX_2 and SnX_4 , where $\text{X} = \text{NO}_3$, $\frac{1}{2}\text{SO}_4$, $\frac{1}{2}\text{PO}_4$, &c. Some of the hydrates of SnO_2 also react as weak acids, especially $\text{SnO}_2 \cdot \text{H}_2\text{O}$ ($= \text{H}_2\text{SnO}_3$), from which is derived a series of *stannates* MSnO_3 , $\text{M} = \text{Na}$, Ca , Pb , &c.; and $x\text{SnO}_2 \cdot x\text{H}_2\text{O}$ ($= x\text{H}_2\text{SnO}_3$), x probably = 5, from which a series of *metastannates*, $x\text{MSnO}_3$ is derived. Stannic and metastannic acids and salts derived from them are described under the heading **TIN OXYACIDS AND SALTS AND DERIVATIVES THEREOF** (p. 727). The oxides SnO and SnO_2 are described in this section of the article **TIN**, and a brief account is also given of the experiments on the hydrates of these oxides other than stannic and metastannic acids.

When tin is strongly heated in air or oxygen a film forms on the surface consisting of SnO and SnO_2 ; at a full red heat, or incipient white heat, tin burns to SnO_2 . According to Vignon (*C. R.* 107, 734), tin ppd. by zinc from neutral SnCl_2Aq or SnCl_4Aq oxidises easily in air; after being exposed to the air for some days it contains from 20 to 33 p.c. SnO . Emich (*M.* 14, 345) found that the surface of tin that was kept molten in the air became covered with crystalline nodules of SnO_2 .

STANNOUS OXIDE SnO . (Protoxide of tin.) Mol. w. not known.

Formation.—1. By heating finely-divided tin in the air; the metal becomes covered with a film of SnO (Vignon, *C. R.* 108, 96). Also by exposing tin ppd. by zinc from SnCl_2Aq or SnCl_4Aq to the air at ordinary temperatures (V., *C. R.* 107, 734).—2. By dehydrating $\text{SnO}_2 \cdot x\text{H}_2\text{O}$, ppd. from SnCl_2Aq by alkali carbonates, either by heating in a stream of CO_2 , or by boiling with water containing a little KOH .—3. By dissolving $\text{SnO}_2 \cdot x\text{H}_2\text{O}$ in cold KOH aq, and allowing the solution to stand in the air (Ditte, *A. Ch.* [5] 27, 145).—4. By heating SnC_2O_4 in a tube of hard glass without free access of air (Liebig, *A.* 95, 116).—5. By ppg. a stannous salt by KCN aq, and boiling the pp. for some days with KON aq (Varenne, *C. R.* 89, 360).

Preparation.— SnCl_2Aq is ppd. by $\text{Na}_2\text{CO}_3\text{Aq}$, the white pp. of $\text{SnO} \cdot \text{H}_2\text{O}$ is thoroughly washed with cold water, and is then boiled with water containing a little KOH aq or NaOH aq (less than sufficient to dissolve the pp.), when the $\text{SnO}_2 \cdot x\text{H}_2\text{O}$ is gradually dehydrated, and small black, lustrous crystals of SnO are obtained (Fremy, *A. Ch.* [3] 12, 460).—2. Tin is dissolved in warm HCl aq, the solution is evaporated, in contact with tin, until it solidifies to SnCl_2 on cooling; 7 parts, or rather more, $\text{Na}_2\text{CO}_3 \cdot 10\text{H}_2\text{O}$ are then added for each part of SnCl_2 in the basin, and the liquid thus formed is heated with constant stirring until it becomes black, and is then allowed to cool; the brownish-black powder, SnO , thus obtained is thoroughly washed with cold water, and dried at 100° (Sandall, *J. pr.* 14, 254).—3. A solution of SnCl_2 is ppd. by a slight excess of KOH aq in the cold, the pp. is

thoroughly washed and dissolved in cold KOH aq (c. 1 part KOH in 10 parts H_2O); the solution, which should be saturated with $\text{SnO}_2 \cdot x\text{H}_2\text{O}$, is allowed to stand in the air, when SnO is gradually ppd. as small, blue-black, shining crystals (Ditte, *A. Ch.* [5] 27, 145).

Properties and Reactions.—Prepared by any of the methods described above, SnO forms small, black, lustrous, regular crystals (for crystalline form v. Nordenskjöld, *P.* 114, 612). S.G. 6.1 (N., l.c.); 6.6 at 0° (Berzelius; Ditte, *A. Ch.* [5] 27, 145).

According to Fremy (*A. Ch.* [3] 12, 460), another modification of SnO is obtained by heating the black crystals (prepared by the first process given above) to 258° ; the crystals are said to swell up and change into soft, olive-green laminae, without any change in weight.

By evaporating very dilute NH_4Cl aq, holding $\text{SnO}_2 \cdot x\text{H}_2\text{O}$ in suspension, until NH_4Cl began to crystallise, Fremy (*A. Ch.* [3] 12, 460) obtained a cinnabar-red powder, which he took to be a third form of SnO . Roth (*A.* 60, 214) obtained red, crystalline SnO by digesting $\text{SnO}_2 \cdot x\text{H}_2\text{O}$, at 56° , with a solution of $\text{SnO}_2 \cdot x\text{H}_2\text{O}$ in acetic acid; the solution containing a little free acetic acid, and having S.G. 1.06.

For the S.G. and appearance of SnO prepared in various ways v. also Ditte (l.c.).

SnO is unchanged in air at ordinary temperatures. According to Ditte (*A. Ch.* [5] 27, 145), SnO that separates from an alkaline solution is unchanged at 300° – 310° ; when heated to redness it is partly decomposed to Sn , and SnO_2 , which combines with unchanged SnO to give $2\text{SnO} \cdot \text{SnO}_2$. SnO is readily converted into SnO_2 by heating with oxidising agents; the change is effected by heating to 500° in NO (Sabatier a. Senderens, *C. R.* 114, 1429). SnO dissolves in acids to form stannous salts, SnX_2 , $\text{X} = \text{NO}_3$, $\frac{1}{2}\text{SO}_4$, $\frac{1}{2}\text{PO}_4$, &c.; it is not acted on by NH_4Aq ; boiled with fairly conc. KOH aq or NaOH aq it gives a solution of an alkali stannate (M_2SnO_3) and tin; heated in Cl forms SnCl_2 and SnO_2 ; mixed with S and strongly heated, SnS_2 and SO_2 are produced; SnO is reduced to tin by heating to redness in H or with C .

HYDRATED STANNOUS OXIDE. The white pp. formed by adding an alkali carbonate to solution of a stannous salt, washing with air-free cold water, and drying at a temperature not above 80° , is said to have the composition $2\text{SnO} \cdot \text{H}_2\text{O} = \text{Sn}_2\text{O}(\text{OH})_2$. According to Ditte (*A. Ch.* [5] 27, 145) the pp. formed by adding KOH aq or NaOH aq to SnCl_2Aq , washing thoroughly, and drying *in vacuo* at 14° is $\text{SnO} \cdot 2\text{H}_2\text{O} (= \text{SnO}_2 \cdot \text{H}_2\text{O})$. Stannous hydroxide is a yellowish white amorphous powder. It is dehydrated, to SnO , by heating in CO_2 ; also by the action of boiling water containing a little KOH , or a trace of HCl , or acetic acid— HNO_3Aq and $\text{H}_2\text{SO}_4\text{Aq}$ form stannous salts; also by boiling with NH_4Cl aq (Ditte, l.c.). The hydroxide is gradually oxidised by exposure to air to $\text{SnO}_2 \cdot x\text{H}_2\text{O}$. Boiled with conc. KOH aq it gives $\text{K}_2\text{SnO}_3\text{Aq}$ and tin. Many metallic salts are reduced, to lower salts or to the metals, by the action of $\text{SnO}_2 \cdot x\text{H}_2\text{O}$ (for details of the interaction with CuO in presence of alkali v. Lenssen, *J. pr.* 89, 90).

STANNIC OXIDE SnO_2 . (Dioxide of tin.) Mol.

W. unknown; probably at least $\text{Sn}_{10}\text{O}_{20}$ (v. Carnelley a. Walker, *C. J.* 53, 92).

Occurrence.—*Tinstone* is more or less pure SnO_2 ; the percentage of the oxide varies from c. 85 to c. 99, the other constituents are generally SiO_2 , and oxides of Al, Fe, and Mn. *Tinstone* crystallises in quadratic forms. Crystalline SnO_2 has been found in the fused slag from a furnace used for casting gun-metal (Abel, *C. J.* 10, 119).

Formation.—1. By exposing molten tin to the action of the air (Emich, *M.* 14, 345).—2. By heating to c. 600° $\text{SnO}_2 \cdot x\text{H}_2\text{O}$ formed by the interaction of tin and HNO_3Aq , or of alkalis and stannic salts, or of alkali stannates and dilute acids.—3. By strongly heating SnO or $\text{SnO} \cdot x\text{H}_2\text{O}$.—4. By passing a mixture of vapour of SnCl_4 and steam through a red-hot tube.—5. By heating SnC_2O_4 , in small quantities, in contact with the air (Vogel, *C. C.* 1855. 413).—6. By passing a little CO_2 into a dilute solution of an alkali stannate (Ditte, *A. Ch.* [6] 30, 282).

Preparation.—A. Crystalline stannic oxide.—1. Molten tin is kept in contact with the air until the surface becomes covered with crystalline nodules of SnO_2 (Emich, *M.* 14, 345). 2. A stream of CO_2 is passed through SnCl_4 , and then through a red-hot porcelain tube through which a current of steam is passed at the same time (Daubrée, *C. R.* 29, 227).—3. Amorphous SnO_2 is strongly heated in a rapid current of dry HCl (Deville, *C. R.* 53, 161).—4. SnC_2O_4 is strongly heated, in small quantities at a time, in an open porcelain or silver dish (Vogel, *C. C.* 1855. 413).

B. Amorphous stannic oxide.—5. The hydrated stannic oxide obtained by ppg. a stannic salt by an alkali, decomposing an alkali stannate solution by dilute acid, or by treating tin with HNO_3Aq , is thoroughly washed and dried, and then heated to c. 630° , at which temperature dehydration is complete (Carnelley a. Walker, *C. J.* 53, 83).

Properties.—Crystalline stannic oxide is a hard, lustrous, white solid. It is dimorphous. Prepared by heating the amorphous oxide in HCl gas, SnO_2 crystallises in quadratic forms isomorphous with *tinstone* and *anatase* (TiO_2) (Daubrée, *C. R.* 29, 227); prepared by decomposing vapour of SnCl_4 by steam, it crystallises in trimetric prisms isomorphous with *brookite* (TiO_2). S.G. of crystalline $\text{SnO}_2 = 6.7$ to 6.85 (Playfair a. Joule, *C. J.* 1, 187; Mallet, *J.* 3, 705; Bergemann, *J.* 10, 661; Daubrée, *C. R.* 29, 227). The crystals obtained by long continued heating molten tin in air had S.G. 7.0096 at 4° (Emich, *M.* 14, 345). Crystalline SnO_2 is hard enough to scratch glass. The amorphous oxide has S.G. 6.6 to 6.9 (F. a. J., l.c.; Herapath, *P. M.* 64, 321; Boullay, *A. Ch.* [2] 43, 266). It is a hard, yellowish-white powder. SnO_2 has not been fused. It is not acted on by acids (but v. *Reactions*, No. 6). Fusion with KOH or NaOH forms M_2SnO_3 , which dissolves in water. The product of fusion with KHSO_4 dissolves in water, but addition of more water ppt. all the tin as $\text{SnO}_2 \cdot x\text{H}_2\text{O}$.

Mallet (*C. J.* 35, 524) obtained a compound $\text{SnO}_2 \cdot \text{HCl}$, to which he gave the formula $\text{SnO} \cdot \text{OH} \cdot \text{Cl}$, and the name *chlor-stannic acid*, by keeping SnCl_4 for a year or two in a loosely stoppered bottle.

Reactions.—1. Fusion with sulphur produces SnS_2 and SO_2 .—2. When strongly heated in chlorine SnCl_4 is formed.—3. SnO_2 is reduced to tin by heating to a high temperature in hydrogen, or with potassium, sodium, or carbon, or in carbonic oxide.—4. Fusion with caustic potash or caustic soda forms alkali stannate (M_2SnO_3), which dissolves in water.—5. Heating with phosphorus trichloride to 160° forms SnCl_4 , SnCl_3 , and P_2O_5 (Michaelis, *J. Z.* 6, 239; 7, 110).—6. According to Ditte (*C. R.* 104, 172), SnO_2 dissolves very slowly in hot sulphuric acid (1 acid to 8 water), and on concentrating till not more than 3 or 4 vols. water are present to 1 vol. H_2SO_4 , crystals of $\text{SnO}_2 \cdot 2\text{H}_2\text{SO}_4$ separate.

HYDRATED STANNIC OXIDE. Carnelley a. Walker (*C. J.* 53, 60, 68, 83) examined the dehydrating action of heat on $\text{SnO}_2 \cdot x\text{H}_2\text{O}$, obtained by decomposing $\text{Na}_2\text{SnO}_3\text{Aq}$ by cold dilute HClAq and drying the pp. in the air for five months. The pp. lost less and less weight for each increase of c. 10° from 50° to c. 110° , at which temperature rather less water was present than corresponded with the formula $\text{SnO}_2 \cdot \text{H}_2\text{O}$, the loss of weight for each rise of 10° was then approximately constant up to c. 360° , at which temperature the composition was nearly that required by the formula $3\text{SnO}_2 \cdot \text{H}_2\text{O}$; at a little above 360° the solid changed colour from brown to pale yellow, and at the same time lost weight at a rate nearly three times as great as during the previous rise of 100° ; after changing colour the solid had the composition $7\text{SnO}_2 \cdot 2\text{H}_2\text{O}$; the loss of weight, per 10° increase, then decreased very much for the next 30° or 40° , and after that dehydration continued irregularly until at 630° – 635° the oxide SnO_2 remained. From these results, considered with results obtained by the same method for other hydrated oxides, C. a. W. concluded that probably a large number of hydrates of SnO_2 exists, but that none of these is stable through more than a very small range of temperature. The results of J. van Bemmelen (*B.* 13, 1466) on the dehydration by heat of stannic hydrates, obtained by oxidising tin by HNO_3Aq , and by decomposing SnCl_4Aq by CaCO_3 , and on the rehydration of the products obtained by heat, by placing them in air more or less saturated with moisture, at different temperatures, show that the quantity of water of hydration varies with variations in temperature, in the molecular states of the solids, and in the moistness of the surrounding air. Not only does the quantity of water of hydration vary with variations in the molecular state of the hydrates, but the firmness or looseness wherewith the water is held also varies much as the molecular condition varies. According to J. van B. the loosely held water is given up in dry air; and when the product is placed in moist air water is taken up until a state of equilibrium is attained wherein as many molecules of water are taken up as are lost in the unit of time.

The following compositions have been given to different hydrates of SnO_2 .

I. *Hydrates obtained by decomposing soluble stannates by dilute acids:* (1) $3\text{SnO}_2 \cdot 7\text{H}_2\text{O}$, by drying in a stream of dry air (Fremy, *A. Ch.* [8] 12, 463); (2) $\text{SnO}_2 \cdot 2\text{H}_2\text{O}$, by drying in the air at the ordinary temperature (Weber, *P.* 122, 358); (3) $\text{SnO}_2 \cdot \text{H}_2\text{O}$, by drying *in vacuo* (Fremy,

(*l.c.*); (4) $8\text{SnO}_2 \cdot 2\text{H}_2\text{O}$, by drying at 140° (Freymy, *l.c.*); to these should probably be added (5) $7\text{SnO}_2 \cdot 2\text{H}_2\text{O}$, by drying at $c. 365^\circ$ (Carnelley & Walker, *l.c.*).

II. *Hydrates obtained by oxidising tin* by HNO_3Aq : (6) $5\text{SnO}_2 \cdot 10\text{H}_2\text{O}$, by drying at the ordinary temperature (Freymy, *l.c.*); (7) $5\text{SnO}_2 \cdot 5\text{H}_2\text{O}$, by drying at the ordinary temperature (Thomson, *Ann. Phil.* 1817, 149), by drying over H_2O (Weber, *l.c.*), by drying *in vacuo*, or at 100° (Freymy, *l.c.*); (8) $5\text{SnO}_2 \cdot 4\text{H}_2\text{O}$, by drying at 130° (Freymy, *l.c.*); (9) $5\text{SnO}_2 \cdot 3\text{H}_2\text{O}$, by drying at 160° (Freymy, *l.c.*); (10) $2\text{SnO}_2 \cdot \text{H}_2\text{O}$, by drying at 55° (Thomson, *l.c.*).

The hydrates obtained by decomposing stannates by dilute acids, or by ppg. stannic salts by CaCO_3 or BaCO_3 , differ in properties from the hydrates obtained by oxidising tin by HNO_3Aq ; the former are generally distinguished as *stannic hydrates*, and the latter as *metastannic hydrates*. The stannic hydrates, dried in air, form hard, semi-transparent lumps, like gum arabic; soluble in the stronger acids, forming stannic salts SnX_4 , where $\text{X} = \text{NO}_3, \frac{1}{2}\text{SO}_4, \&c.$; soluble in alkali solutions, forming stannates M_2SnO_4 (*v. Stannates*, under TIN OXYACIDS, AND SALTS AND DERIVATIVES THEREOF, *infra*). Metastannic hydrates are white solids (? crystalline) that do not dissolve in HNO_3Aq , or $\text{H}_2\text{SO}_4\text{Aq}$ (*v. infra*). These hydrates interact with HClAq , and the product is soluble in water but insoluble in conc. HClAq ; according to Weber (*P.* 122, 358), the solution gives $\text{SnCl}_4 \cdot 3\text{SnO}_2 \cdot 5\text{H}_2\text{O}$, when evaporated over H_2SO_4 ; by prolonged boiling, with fresh additions of water, all the tin in the solution is ppd. as metastannic hydrate (Freymy, *A. Ch.* [3] 12, 463; 23, 393). Metastannic hydrates dissolve in KOH Aq and NaOH Aq , forming metastannates $\text{M}_2\text{H}_2\text{SnO}_5$ (*v. Metastannates*, under TIN OXYACIDS, AND SALTS AND DERIVATIVES THEREOF, p. 730).

According to Ditte (*C. R.* 104, 172), both stannic and metastannic hydrates dissolve in warm $\text{H}_2\text{SO}_4\text{Aq}$ (1 part acid and 8 parts water), and on concentrating till not more than 3 to 4 vols. water are present to 1 vol. H_2SO_4 , the solution deposits white crystals of $\text{SnO}_2 \cdot 2\text{H}_2\text{SO}_4$; these crystals are very deliquescent; they are decomposed by water; if so much water is added that not more than 43 g. H_2SO_4 are present in 1,000 c.c. of the liquid, a pp. of $\text{SnO}_2 \cdot x\text{H}_2\text{O}$ is formed. By dissolving stannic or metastannic hydrate in warm $\text{H}_2\text{SeO}_4\text{Aq}$, and concentrating, D. (*l.c.*) obtained crystals of $\text{SnO}_2 \cdot 2\text{H}_2\text{SeO}_4$.

For further details of reactions of stannic and metastannic hydrates *v. TIN OXYACIDS, AND SALTS AND DERIVATIVES THEREOF (infra)*.

OXIDES OF TIN OTHER THAN STANNOUS AND STANNIC OXIDES. Oxides which are most simply regarded as $x\text{SnO}_2 \cdot y\text{SnO}$, seem to exist.

According to Fuchs (*J. pr.* 5, 318), a greyish-white, slimy solid, having the composition $\text{SnO} \cdot \text{SnO}_2 (= \text{Sn}_2\text{O}_3)$, is obtained by diffusing freshly ppd. $\text{Fe}_2\text{O}_3 \cdot x\text{H}_2\text{O}$ in SnCl_4Aq free from acid, and boiling

($2\text{SnCl}_4\text{Aq} + \text{Fe}_2\text{O}_3 = \text{SnO} \cdot \text{SnO}_2 + 2\text{FeCl}_4\text{Aq}$). This oxide is said to dissolve completely in NH_3Aq , and also in HClAq .

By digesting $\text{SnO}_2 \cdot x\text{H}_2\text{O}$, ppd. by alkali from SnCl_4Aq , with SnCl_4Aq , Schiff (*A.* 120, 53) obtained an orange-yellow solid, to which he gave

the composition $\text{SnO} \cdot 6\text{SnO}_2 \cdot 5\text{H}_2\text{O}$; by digesting $\text{SnO}_2 \cdot x\text{H}_2\text{O}$, formed by oxidising tin with HNO_3Aq , with SnCl_4Aq , Schiff (*l.c.*) obtained a yellow powder, said by him to be $\text{SnO} \cdot 6\text{SnO}_2 \cdot 9\text{H}_2\text{O}$, or when dried at 85° to be $\text{SnO} \cdot 6\text{SnO}_2 \cdot 4\text{H}_2\text{O}$ (*v. also* Tschermak, *C. C.* 1862, 305).

PURPLE OF CASSIUS. A purple-coloured solid is obtained by adding solution of a stannous salt to dilute AuCl_3Aq ; this solid has been examined by many chemists, who have generally assigned to it formulæ which represent it as a compound of SnO_2 , sometimes of $\text{SnO} \cdot \text{SnO}_2$, and AuO . According to the most recent investigations the composition varies according to the conditions of preparation, and all that can be said with certainty is that the purple solid is a compound of tin, gold, and oxygen (*v. Buisson, J. Ph.* 16, 629; Böhlen, *Ar. Ph.* 57, 277; Capaun, *J. pr.* 22, 153; Fuchs, *J. pr.* 5, 318; Wächter, *A.* 68, 116; Figuier, *Ph. C.* 1844, 724; Debray, *C. R.* 100, 1035; Müller, *J. pr.* [2] 30, 252; and, for a bibliography (to 1866), Fischer, *D. P. J.* 182, 39).

Tin oxyacids, and salts and derivatives thereof. Some of the hydrates of SnO_2 interact with alkalis to produce salts wherein tin forms part of the acidic radicle; compounds are also known the acidic radicles whereof contain tin in combination with other negative elements besides oxygen, or tin in combination with both metallic and nonmetallic elements.

The reactions of the hydrates of SnO_2 , ppd. from solutions of stannates by dilute cold acids, or ppd. from stannic salts by alkalis, are distinctly different from the reactions of the hydrates of SnO , obtained by oxidising tin by HNO_3Aq , or by ppg. by dilute acids from solutions of another class of salts which have the same composition as stannates, except that they always contain H and O in the ratio $2\text{H}:\text{O}$ in addition to the constituents of stannates. It is therefore usual to distinguish the acidic hydrates of SnO_2 as *stannic* and *metastannic acids*; to the former is given the composition $\text{H}_2\text{SnO}_3 (= \text{SnO}_2 \cdot \text{H}_2\text{O})$, and to the latter the composition $\text{H}_2\text{Sn}_2\text{O}_5 (= 5\text{SnO}_2 \cdot 5\text{H}_2\text{O})$. Neither of these formulæ is to be regarded as more than an attempt to connect the differences in the chemical behaviour of two compounds having identical percentage compositions (if the H_2O in one class is omitted) with differences in the complexities of their interacting atomic aggregates; the molecular weight of neither compound is known. It is, indeed, doubtful whether a compound with the composition $x\text{H}_2\text{SnO}_3$ can exist apart from other hydrates of the composition $y\text{SnO}_2 \cdot x\text{H}_2\text{O}$; it is certain that the composition of the hydrates of SnO_2 varies with very small variations of temperature, by whatever methods these hydrates are prepared (*v. p.* 726, HYDRATED STANNIC OXIDE).

That the hydrates of SnO_2 , obtained respectively by ppg. solution of stannates by dilute acids and by oxidising tin by HNO_3Aq , differed in their reactions, was noticed by Berzelius in 1811 (*v. Lehrbuch* [5th ed.] 2, 596). Berzelius regarded these compounds as hydrates of two different modifications of stannic oxide; he called the oxide supposed to be a constituent of the hydrates obtained by ppg. solutions of stannates *stannic oxide*, and designated it as αSnO_2 ; the other

oxide he called *metastannic oxide*, and designated it as δSnO_2 . Gmelin called the hydrate from stannates *ordinary stannic acid*, and the other hydrate *abnormal stannic acid*.

STANNIC ACID H_2SnO_3 .

Preparation.—By adding cold dilute HClAq to an aqueous solution of K_2SnO_3 , prepared by fusing SnO_2 with KOH , or by heating tin with KOH and KNO_3 (*v. POTASSIUM STANNATE*, p. 730), a gelatinous pp. is obtained which, when washed and dried *in vacuo*, has the composition $\text{SnO}_2 \cdot \text{H}_2\text{O} = \text{H}_2\text{SnO}_3$ (Freymy, *A. Ch.* [3] 12, 463). The same hydrate is formed, according to F. (l.c.), by adding CaCO_3 or BaCO_3 to excess of SnCl_4Aq , washing, and drying *in vacuo*. (For details regarding the results obtained by different chemists who have examined the compositions of the stannic hydrates, *v. HYDRATED STANNIC OXIDE*, p. 726). Graham (*T.* 1861. 213) obtained colloidal stannic acid (no analyses are given) by dissolving $\text{SnO}_2 \cdot x\text{H}_2\text{O}$ ppd. from a stannic salt (? by alkali from SnCl_4Aq) in SnCl_4Aq , and dialysing until all the Cl had passed into the dialysate. Colloidal forms of stannic acid are also obtained (1) by dialysing a solution of the ppd. acid in HClAq or in an alkali; (2) by the action of CO_2 , or of air, on an alkaline solution of the ppd. acid (J. van Bemmelen, *R. T. C.* 7, 87; *abstract in C. J.* 54, 1160 [1888]; the results of experiments on the dehydration of the colloidal acid are given).

Properties and Reactions.—A gelatinous, amorphous solid, drying (in air or *in vacuo*) to hard, semi-transparent lumps, like gum-arabic. Reddens litmus paper. Vignon (*C. R.* 108, 1049) found that the heat of neutralisation, by KOH Aq , of stannic acid formed by ppg. SnCl_4Aq by KOH Aq , decreased when the ppd. acid was kept in contact with water for some days, and decreased more rapidly when the acid was heated with water in a sealed tube for some hours. J. van Bemmelen (*J. pr.* [2] 23, 324) found that when stannic acid is shaken with solutions of HCl , or H_2SO_4 , or with solutions of certain salts, such as KCl or K_2SO_4 , a definite number of molecules of the acid or salt is taken up by the stannic acid so as to form a loose combination therewith; and that the number of molecules thus absorbed varies with the proportion between the quantities of stannic acid and the acid or salt in the solution used, and also with the concentration of the solution used. The loose compounds thus formed are called *absorption-compounds* by J. van B. Dissolves in the stronger acids (HNO_3 , H_2SO_4 , HCl , &c.). According to Ditté (*C. R.* 104, 172), when a solution of stannic acid in warm $\text{H}_2\text{SO}_4\text{Aq}$ (1 part acid to 8 parts water) is evaporated until not more than 3 to 4 vols. water are present to 1 vol. H_2SO_4 , and allowed to cool, it yields white deliquescent crystals of $\text{SnO}_2 \cdot 2\text{H}_2\text{SO}_4$; and a solution of stannic acid in warm $\text{H}_2\text{SeO}_4\text{Aq}$ yields a similar crystalline compound $\text{SnO}_2 \cdot 2\text{H}_2\text{SeO}_4$. Dissolves in excess of caustic alkali solutions, forming stannates (*q. v.* p. 730) M_2SnO_3 . According to J. van B. (l.c.) colloidal stannic acid does not form any compound when shaken with dilute cold KOH Aq , but only complex molecular aggregates, the composition of which varies considerably with temperature and concentration. Stannic acid, dried at the ordinary temperature by pressure, is

gradually changed to metastannic acid by heat; the change begins at c. 55° (J. van B., l.c.; *v. also infra*, *Change of stannic to metastannic acid, and vice versa*). For other reactions of stannic acid *v. infra*, *Distinctions between stannic and metastannic acids*.

METASTANNIC ACID $\text{H}_{10}\text{Sn}_2\text{O}_{15}$.

Preparation.—Tin, in thin pieces or granulated, is heated with HNO_3Aq , S.G. c. 1.35, until the metal is converted into a greyish-white powder, which is washed with dilute HNO_3Aq , and then with water, and dried. The solid is said to have the composition $\text{H}_{10}\text{Sn}_2\text{O}_{15}$ ($= 5\text{SnO}_2 \cdot 5\text{H}_2\text{O}$) when dried *in vacuo* (Freymy, *A. Ch.* [3] 12, 463), when dried over H_2SO_4 (Weber, *P.* 122, 358), or when dried at the ordinary temperature (Thomson, *Ann. Phil.* 1817. 149). For details of the results obtained by different chemists who have examined the compositions of the metastannic hydrates *v. HYDRATED STANNIC OXIDE* (p. 726); *v. also J. van Bemmelen, R. T. C.* 7, 87 (*abstract in C. J.* 54, 1160 [1888]). It should be noted that the empirical formula assigned to metastannic acid dried *in vacuo* (Freymy), or dried over H_2SO_4 (Weber), is the same as that assigned to stannic acid dried *in vacuo* (Freymy); this formula is $\text{SnO}_2 \cdot \text{H}_2\text{O}$. The different reactions of the two compounds show that if both have the same empirical formula one must be an isomeride or a polymeride of the other. Metastannic acid is also obtained by decomposing an aqueous solution of the sodium salt (*v. p.* 730, *Metastannates*) by boiling. Graham (*T.* 1861. 213) obtained colloidal metastannic acid by adding a little HClAq to the acid obtained by the action of HNO_3Aq on tin, dissolving the solid so formed in water, and dialysing. Vignon (*C. R.* 108, 1049) found that the heat of neutralisation of metastannic acid by KOH Aq decreased when the acid was dried at 110° , and decreased very considerably when the acid was heated with water, for some hours, at 250° in a sealed tube.

Properties and Reactions.—A white powder. Insol. in nitric acid. Contact with conc. HClAq for a short time produces a compound (according to J. van Bemmelen, *R. T. C.* 7, 87; *abstract in C. J.* 54, 1160 [1888], no definite compound is formed, but only complex molecular aggregates of metastannic acid and HCl) which dissolves in water, but is insol. in HClAq . According to Barfoed (*J. pr.* 101, 368), the compound with HCl is quite insol. in HClAq S.G. 1.1, and may be purified by washing with acid of that concentration. The solution of this substance in water gives off HCl and H_2O , with a very little SnCl_4 , when distilled; and metastannic acid separates out (Freymy, *A. Ch.* [3] 12, 463; 23, 393; H. Rose, *A.* 68, 272). Evaporation of the aqueous solution over H_2SO_4 is said to give an oxychloride $3\text{SnO}_2 \cdot \text{SnCl}_4 \cdot 5\text{H}_2\text{O}$ (Weber, *P.* 123, 358). Metastannic hydrate dissolves in conc. HClAq after prolonged boiling, forming SnCl_4 solution (Löwenthal, *J. pr.* 77, 321). Barfoed (l.c.) says that conc. HClAq gradually converts recently ppd. and moist metastannic acid into stannic acid, and that the quantity of metastannic acid thus changed increases with the quantity of conc. HClAq , the time of contact, and the temperature. J. van Bemmelen (*J. pr.* [2] 23, 324) found that metastannic acid forms *absorption-compounds* with HCl , H_2SO_4 , KCl , K_2SO_4 , &c.

(*cf.* STANNIC ACID, *Properties*, p. 728). For other reactions of the solution in water of the product of the action of HClAq on metastannic acid *v. infra*, *Distinctions between stannic and metastannic acids*. According to Ditte (*C. R.* 104, 172), metastannic acid dissolves in warm $\text{H}_2\text{SO}_4\text{Aq}$ (1 pt. acid to 8 pts. water), forming a solution which gives crystals of $\text{SnO}_2 \cdot 2\text{H}_2\text{SO}_4$, when evaporated until not more than 3 to 4 vols. water are present for one vol. H_2SO_4 ; the crystals are decomposed by water, with ppn. of $\text{SnO}_2 \cdot x\text{H}_2\text{O}$ (? metastannic hydrate), when sufficient water is added to insure that not more than 43 g. H_2SO_4 are present in 1,000 c.c. of the liquid. A similar compound was obtained with selenic acid, viz. $\text{SnO}_2 \cdot 2\text{H}_2\text{SeO}_4$ (*D., l.c.*). Allen (*C. J.* 25, 274) found that metastannic acid dissolved in boiling conc. H_2SO_4 , forming $\text{Sn}(\text{SO}_4)_2$ solution; by pouring this solution into water some of the tin was pptd., after a time, as stannic acid, but on boiling the whole of the tin came down as metastannic acid. Metastannic acid is said to dissolve slowly in fairly dilute cold KOHAq or NaOHAq; addition of conc. KOHAq or NaOHAq is said to ppt. K or Na metastannate; when the solution in KOHAq or NaOHAq stands in the air metastannic acid gradually deposits. According to J. van Bemmelen (*l.c.*), colloidal metastannic acid does not form any definite compound with KOH when shaken with KOHAq of different concentrations. By fusing metastannic acid with KHSO_4 or NaHSO_4 , Allen (*C. J.* 25, 274) obtained a product which dissolved partially in water; the aqueous solution gave a pp. of metastannic acid on boiling.

Distinctions between stannic and metastannic acids (*v. Fremy, A. Ch.* [3] 12, 462; 23, 393; *H. Rose, P.* 75, 1; 105, 561; Löwenthal, *J. pr.* 77, 321; Barfoed, *J. pr.* 101, 368; J. van Bemmelen, *R. T. C.* 7, 87; *abstract in C. J.* 54, 1160 [1888]).—Stannic acid is soluble in dilute HNO_3Aq , $\text{H}_2\text{SO}_4\text{Aq}$, or HClAq; metastannic acid is insol. in these acids. Cold conc. HClAq dissolves stannic acid, and the solution gives the reactions of SnCl_4 ; cold conc. HClAq forms a compound (? molecular aggregates) with metastannic acid, which is insol. HClAq of S.G. 1.1, or greater S.G., but dissolves in cold water.

The following reactions apply to solutions of stannic acid in HClAq on the one hand, and to solutions in water of the substance formed by the action of HClAq on metastannic acid on the other hand. Stannic acid solution, if conc., does not become turbid on boiling; long continued boiling, with additions of water, ppts. all the acid. Metastannic acid solution, even when conc., goes turbid on boiling; long-continued boiling, accompanied by dilution, ppts. all the acid. Stannic acid solution, when distilled, gives off H_2O , with a little HCl and SnCl_4 ; and a little stannic acid separates. According to Barfoed (*J. pr.* 101, 368), when a solution of stannic acid in HClAq S.G. 1.1 is distilled, the whole of the tin passes over as SnCl_4 . Metastannic acid solution, when distilled, gives off H_2O , with some HCl and a very little SnCl_4 , and the meta-acid separates in the retort. Addition of tartaric acid to the stannic solution, followed by gradual addition of NH_3Aq , excess of NH_3Aq being avoided, produces no pp. Treatment of the metastannic solution with tartaric acid and NH_3Aq (not in

excess) ppts. the meta-acid. SnCl_4Aq gives no pp. with the stannic solution; SnCl_4Aq gives a yellowish pp. (? $\text{SnO} \cdot 6\text{SnO}_2 \cdot 9\text{H}_2\text{O}$) with the metastannic solution. Addition of dilute $\text{H}_2\text{SO}_4\text{Aq}$ to the stannic solution produces no pp., unless the stannic solution is very much diluted. Dilute $\text{H}_2\text{SO}_4\text{Aq}$ produces a pp. even in very dilute metastannic solution; by washing this pp. with hot water, metastannic acid remains (*cf.* Ditte's experiments are described under both STANNIC ACID and METASTANNIC ACID, pp. 728, 729). The stannic solution is not pptd. by conc. HClAq. The metastannic solution, if nearly neutral, is pptd. by conc. HClAq. Addition of $\text{K}_2\text{FeCy}_6\text{Aq}$ to the stannic solution, in the ratio $\text{K}_2\text{FeCy}_6\text{:Sn}$ present, ppts. all the tin as SnFeCy_6 . To ppt. all the tin from the metastannic solution, the $\text{K}_2\text{FeCy}_6\text{Aq}$ must be added in c. the ratio $19\text{K}_2\text{FeCy}_6\text{:Sn}$ present; the pp. is not SnFeCy_6 , it is said by some observers to be metastannic acid; J. van B. (*l.c.*) calls it an *absorption compound* of metastannic acid and K_2FeCy_6 . The stannic solution gives no pp. with excess of fairly conc. NaOHAq. The metastannic solution is completely pptd., as sodium metastannate, by excess of fairly conc. NaOHAq.

Change of stannic to metastannic acid and vice versa. A solution of stannic acid in HClAq gradually changes to metastannic acid; the change is the more rapid and complete the more dilute the solution (*H. Rose, l.c.*; Barfoed, *l.c.*); by boiling for some time with repeated additions of water the whole of the stannic acid may be converted into metastannic acid. A very conc. solution of stannic acid in HClAq remains unchanged (*cf.* reaction of meta-acid with conc. HClAq, *infra*). According to Löwenthal (*l.c.*), the change from stannic to metastannic acid is stopped by addition of tartaric acid, even when the solution of stannic acid in HClAq is dilute; the amount of change to the meta-acid may be determined (according to L., *l.c.*) by finding the quantity of $\text{K}_2\text{FeCy}_6\text{Aq}$ required to completely ppt. the tin in solution. Barfoed (*l.c.*) says the best way to measure the amount of change is to add excess of fairly conc. NaOHAq, which ppts. all the meta-acid (as a sodium salt) but none of the stannic acid.

Stannic acid is converted into the meta-acid by heat (*H. Rose, l.c.*). J. van Bemmelen (*l.c.*) found that stannic acid dried by pressure at the ordinary temperature is completely soluble in conc. HClAq, but that by heating to c. 55° , or by heating with water to below 100° , some metastannic acid is formed which is insoluble in conc. HClAq.

A solution of stannic acid in excess of KOHAq gradually deposits metastannate of K on exposure to air, with formation of $\text{K}_2\text{CO}_3\text{Aq}$.

Metastannic acid is gradually changed to stannic acid, according to Barfoed (*l.c.*), by contact with conc. HClAq; the quantity of stannic acid produced increases with the quantity of HClAq used, the time of contact, and the temperature.

Stannic acid is said to be obtained from the meta-acid by fusing the latter with a large excess of KOH, dissolving in water, and ppg. by cold dilute HClAq (*H. Rose, l.c.*; Fremy, *l.c.*).

OXYACIDS OF TIN OTHER THAN STANNIC AND METASTANNIC. (1) H_2SnO_3 . Spring (*Bt.* [3] 1,

180) obtained a colloidal solid, drying at 100° to a white mass with the composition $H_2Sn_2O_7$, by adding excess of $BaO_2 \cdot xH_2O$ to a solution of $SnCl_4$ in $HClAq$, and dialysing the turbid liquid until $BaCl_2$ ceased to pass into the dialysate. S. regarded the new compound as an acid of the hypothetical perstannic oxide SnO_3 , analogous to CeO_3 , TiO_3 , and (?) ZnO_3 . (2) $H_2Sn_2O_7$ and $H_2Sn_2O_9$. The empirical formula of both these hydrates of stannic oxide is $SnO_2 \cdot H_2O$. According to Musculus (*C. R.* 65, 961), the hydrates differ somewhat in properties both from stannic and metastannic acids; they are said to be formed by keeping stannic acid under water, and to form K salts, $KH_2Sn_2O_7$ and $KH_2Sn_2O_9$.

STANNATES, $M^I_2SnO_4$ and $M^{IV}SnO_4$. The alkali stannates are obtained by dissolving stannic acid in $MOHAq$ ($M = NH_4$, K, or Na), and evaporating over H_2SO_4 ; the stannates of the alkaline earth metals may be obtained by the interactions of solutions of the alkali stannates with MO_2H_2 or MCO_3 ($M = Ba, Ca, Sr$).

Ammonium stannate. A salt, said to have the composition $(NH_4)_2SnO_4 \cdot xH_2O$, is obtained, as a yellowish jelly, by evaporating a solution of stannic acid in NH_4Aq over H_2SO_4 (Moberg, *J. pr.* 28, 230). When K_2SnO_4Aq is added to NH_4ClAq , stannic acid is pptd. according to Ditte (*C. R.* 96, 701).

Barium stannate. The normal salt $BaSnO_4 \cdot 6H_2O$ is said to be obtained by adding $BaCl_2Aq$ to K_2SnO_4Aq ; it is described as a heavy, white powder (Moberg, *l.c.*). By adding K_2SnO_4Aq to excess of $BaCl_2Aq$, Ditte (*l.c.*) obtained a basic salt $BaSnO_4 \cdot BaO \cdot 10H_2O$ as lustrous leaflets.

Calcium stannate. Ditte (*l.c.*) obtained the normal salt $CaSnO_4 \cdot 6H_2O$, in white crystals, by adding K_2SnO_4Aq to excess of $CaCl_2Aq$, washing, and drying at 100° . By heating for some hours a mixture of stannic acid and $CaCl_2Aq$, with a little CaO , D. obtained $CaSnO_4$ in regular crystals.

Potassium stannate $K_2SnO_4 \cdot xH_2O$. Prepared by dissolving stannic acid in $KOHAq$, or by fusing SnO_2 or metastannic acid with excess of KOH for some time and dissolving in water, and evaporating over H_2SO_4 ; transparent, rhombic prisms; crystallising with $4H_2O$ (Freymy, *A. Ch.* [3] 23, 393), with $3H_2O$ (Moberg, *l.c.*). Marignac (*Ann. M.* [3] 15, 277) obtained the salt, in rhombohedral crystals, by gradually heating 3 pts. metastannic acid with 8 pts. KOH till the mixture boiled, allowing to cool, dissolving in water, filtering, and evaporating. Ordway (*Am. S.* [2] 40, 173) prepared the pure salt by adding an equal volume of absolute alcohol to a solution of the commercial salt (*v. infra*), repeatedly treating the syrupy layer that separated with alcohol, drying the pasty mass so obtained by pressure, dissolving in water, evaporating *in vacuo*, and washing the crystals with alcohol. K-stannate dissolves easily in water; O. (*l.c.*) gives S. at $10^{\circ} = 106.6$, and at $20^{\circ} = 110.5$; solution reacts alkaline. Insoluble in alcohol. By adding a dilute acid solution sufficient to neutralise $\frac{1}{2}$ of the alkali, a white flocculent pp. of K metastannate is said to be produced (O., *l.c.*); excess of cold dilute acid ppts. stannic acid. $K_2SnO_4 \cdot xH_2O$ is dehydrated at a red heat.

Commercial stannate of potash solution is prepared (1) by fusing tinstone with K_2S , KOH , or

KNO_3 , and dissolving in water; (2) by boiling tinstone with $KOHAq$; (3) by fusing tin with KNO_3 and K_2CO_3 , or boiling the metal with $KOHAq$ containing KNO_3 and KCl (*v. Haeffely, D. P. J.* 144, 66; Vaughan, *B.* 5, 396; and DICTIONARY OF APPLIED CHEMISTRY, vol. iii. pp. 843-4).

Sodium stannate $Na_2SnO_4 \cdot xH_2O$. Prepared similarly to the K salt. Crystallises in hexagonal plates with $9H_2O$ (M., *l.c.*; O., *l.c.*). Marignac (*l.c.*) obtained rhombohedral crystals. Jonas (*C. C.* 1865, 607) obtained rhombic crystals of $Na_2SnO_4 \cdot 9H_2O$ by recrystallising the commercial salt. Haeffely (*D. P. J.* 144, 66) obtained crystals of $Na_2SnO_4 \cdot 3H_2O$ by heating an aqueous solution of S.G. 1.3; on allowing to cool again the crystals dissolved, the S.G. became 1.35, and after a time crystals of $Na_2SnO_4 \cdot 8H_2O$ were deposited. Scheurer-Kestner (*Bl.* [2] 8, 839) obtained crystals of the composition $Na_2SnO_4 \cdot 10H_2O$ by evaporating a dilute solution of the ordinary salt, free from excess of $NaOH$, at a low temperature. $Na_2SnO_4 \cdot 3H_2O$ is more soluble in cold than in hot water; O. (*l.c.*) gives S. at $0^{\circ} = 67.4$, and at $20^{\circ} = 61.3$. Insoluble in alcohol. According to H. (*l.c.*), an aqueous solution of the octohydrate gives a crystalline pp. of Na metastannate when heated, or when left at the ordinary temperature for some weeks. Commercial stannate of soda solution is prepared similarly to the solution of the potash salt (*v. supra*).

Strontium stannate. A basic salt $2SrSnO_4 \cdot SrO \cdot 10H_2O$ was obtained by Ditte (*C. R.* 96, 701), in lustrous octahedra, by adding K_2SnO_4Aq to excess of $SrCl_2Aq$.

METASTANNATES. Only alkali metastannates have been prepared. The empirical formula of these salts is $M_2O \cdot 5SnO_2 \cdot 4H_2O$; as they are decomposed by removing water, the formula is generally written as $M_2H_2Sn_2O_7$, (*cf. METASTANNIC ACID*, p. 728). Metastannic acid dissolves slowly in $KOHAq$ or $NaOHAq$; on adding conc. $MOHAq$ the salts are pptd. The salts are better obtained by adding conc. $MOHAq$ to a solution in water of the substance obtained by the interaction of metastannic acid and conc. $HClAq$ (Barfoed, *J. pr.* 101, 368). Dilute acid solutions ppt. metastannic acid from solutions of metastannates. Metastannates heated with excess of MOH give stannates. For more details regarding $M_2H_2Sn_2O_7$ ($M = K$ or Na) *v. Freymy (A. Ch.* [3] 23, 393); Weber (*P.* 122, 358); Haeffely (*D. P. J.* 144, 66).

ARSENIO-STANNATES. A compound $Na_2O \cdot 2As_2O_3 \cdot 6SnO_2 \cdot 5H_2O$ was obtained by Haeffely (*D. P. J.* 140, 290) by adding excess of HNO_3Aq to a boiling solution of Na_2SnO_4 and Na_2AsO_4 , and treating the gelatinous pp. with excess of $NaOHAq$.

OXALO-STANNATES. The compound $2KH_2C_2O_4 \cdot SnO_2 \cdot 5H_2O$ was obtained, in lustrous leaflets, by Péchard (*C. R.* 116, 1513) by dissolving stannic acid in hot KHC_2O_4Aq and allowing to cool.

PLATINO-STANNATES. Compounds of SnO and SnO_2 with PtO , derived from the acids $H_2SnPt_2O_6$ and $H_2SnPt_4O_8$ (*v. PLATINO-STANNATES*, this vol. p. 285).

PLATINO-SELENO-STANNATES *v. this vol. p. 285.*

SILICO-STANNATES. Bourgeois (*Bl.* [2] 47, 397) obtained the salt $\text{CaO} \cdot \text{SiO}_2 \cdot \text{SnO}_2$ in monoclinic, lustrous crystals, by fusing SiO_2 and SnO_2 with excess of CaCl_2 , and extracting with water.

In connection with stannic and metastannic acids and their derivatives, v. *Chlor-stannic acid*, under STANNOUS CHLORIDE (p. 721); **TIN, OXIDES AND HYDRATED OXIDES OF** (p. 725); and **TIN, THIO-ACIDS AND SALTS OF** (p. 735).

Tin, oxybromides of. By adding pieces of tin to the mother-liquor from BaSnBr_6 (v. *Stannibromides*, under STANNIC BROMIDE, p. 720). Rayman a. Preis (*A.* 223, 323) obtained colourless, prismatic crystals to which they gave the formula $\text{Sn}_2\text{OBr}_6 \cdot 12\text{H}_2\text{O}$; and from the mother-liquor from this compound fine, colourless needles of $\text{Sn}_2\text{O}_2 \cdot \text{Br}_6 \cdot 10\text{H}_2\text{O}$ separated after a time.

Tin, oxychlorides of. According to Ditte (*A. Ch.* [5] 27, 145), when $\text{SnO}_2 \cdot x\text{H}_2\text{O}$, obtained by ppg. a stannous salt by NH_4Aq , is boiled with water containing a trace of SnCl_2 , a gelatinous oxychloride is obtained having the composition $\text{Sn}_2\text{OCl}_2 \cdot 6\text{H}_2\text{O}$ ($= \text{SnO} \cdot \text{SnCl}_2 \cdot 6\text{H}_2\text{O}$); and when this compound is boiled with a little more dilute SnCl_2Aq another oxychloride, $\text{Sn}_3\text{OCl}_4 \cdot 6\text{H}_2\text{O}$ ($= 3\text{SnO} \cdot 2\text{SnCl}_2 \cdot 6\text{H}_2\text{O}$) is formed in small, white, pearly tablets.

The oxychloride SnOCl_2 is obtained, according to Scheurer-Kestner (*A. Ch.* [3] 47, 1), by evaporating SnCl_2Aq at 50° to 60° ; also by heating 100 pts. $\text{SnCl}_2 \cdot 2\text{H}_2\text{O}$, dissolved in 50 pts. water, with HNO_3Aq containing 16 pts. N_2O_5 .

An oxychloride is also formed by treating metastannic acid with conc. HClAq , pouring off the excess of acid, dissolving in water, and evaporating over H_2SO_4 and CaO ; to this oxychloride, which is an amorphous, white solid, Weber (*P.* 122, 368) gave the formula $\text{Sn}_4\text{O}_3\text{Cl}_4 \cdot 5\text{H}_2\text{O}$ ($= 3\text{SnO}_2 \cdot \text{SnCl}_2 \cdot 5\text{H}_2\text{O}$). Tschermak (*W. A. B.* 44, 2) obtained a crystalline oxychloride $\text{Sn}_4\text{O}_3\text{Cl}_4$ ($= 4\text{SnO}_2 \cdot 3\text{SnCl}_2 \cdot \text{SnCl}_4$) by dissolving moist metastannic acid in hot conc. SnCl_2Aq containing HCl .

Mallet (*C. J.* 35, 524) obtained a semi-transparent, jelly-like solid from SnCl_2Aq which had been kept in a loosely-stoppered bottle for a year or two; to this solid he gave the formula $\text{SnO}_2 \cdot \text{HCl}$ ($= \text{SnO} \cdot \text{OH} \cdot \text{Cl}$).

Tin, oxyfluoride of. When SnF_2 is heated in air it is said to form the oxyfluoride SnOF_2 ($= \text{SnO}_2 \cdot \text{SnF}_4$) (Fremy, *A. Ch.* [3] 47, 37; Marignac, *Ann. M.* [5] 15, 221).

Tin, oxyiodides of. According to Personne (*C. B.* 54, 216), various oxyiodides are formed by decomposing SnI_2 by much water; P. analysed four compounds, to which he assigned the compositions $\text{Sn}_2\text{O}_2\text{I}_2$ ($= 2\text{SnO} \cdot \text{SnI}_2$), Sn_2OI_2 ($= \text{SnO} \cdot \text{SnI}_2$), Sn_3OI_4 ($= \text{SnO} \cdot 2\text{SnI}_2$), and Sn_4OI_6 ($= \text{SnO} \cdot 3\text{SnI}_2$).

Tin, phosphides of. By heating finely divided tin in vapour of P, Schrötter (*W. A. B.* 1849, 301) obtained a silver-white, brittle solid to which he gave the formula SnP ; S.G. 6.56; easily acted on by HClAq , but not by HNO_3Aq . Other crystalline solids have been obtained by heating tin and P together, but their compositions are not determined with certainty (v. *Pelletier*, *S.* 55, 106; *Berthier*, *A. Ch.* [2] 33, 180; *H. Rose*, *P.* 24, 326; *Lüpke*, *C. C.* 1890

[ii.] 643). Natanson a. Vortmann (*B.* 9, 1459) obtained a phosphide of tin by heating glacial phosphoric acid with C and tin; HClAq gave off PH_3 and left SnP .

Tin, salts of. Tin forms two classes of salts by replacing the H of acids; the *stannous* salts SnX_2 , and the *stannic* salts SnX_4 ($\text{X} = \text{ClO}_3$, NO_3 , $\frac{1}{2}\text{CO}_3$, $\frac{1}{2}\text{SO}_4$, $\frac{1}{2}\text{P}_2\text{O}_5$, &c.). The chief salts of oxyacids are the following: (1) *Stannous salts*: antimonate, arsenate, borate, carbonate, chlorate, chromate, iodate, nitrate, phosphates, phosphite, sulphates, and sulphite. (2) *Stannic salts*: antimonate, arsenate, bromate, chlorate, iodate, molybdate, nitrate, phosphates, phosphite, selenate, selenite, sulphates, and tungstates (v. *NITRATES, SULPHATES, &c.*).

Tin, selenides of. Tin and Se form two compounds, SnSe and SnSe_2 . The former can be prepared by the direct union of the elements; the latter does not seem to be obtained by this method. Both selenides dissolve in alkali solutions, and in solutions of alkali sulphides.

STANNOUS SELENIDE SnSe . (*Tin monoselenide or protoselenide*.) Mol. w. unknown. Obtained by melting together Se and tin (Berzelius; Welsmann, *A.* 116, 122). With excess of Se the disulphide SnSe_2 was said to be formed (Little, *A.* 112, 213), but this was probably a mistake (Schneider, *P.* 127, 624). Also formed by adding powdered Se to molten SnCl_2 , heating till SnCl_2 is volatilised, and allowing to cool, when SnSe crystallises; excess of SnCl_2 is removed by washing with dilute HClAq (Schneider, *l.c.*). Steel-grey, lustrous prisms; probably isomorphous with SnS ; S.G. 5.24 at 15° (S., *l.c.*). Also obtained, as a black powder, by passing H_2Se into SnCl_2Aq , washing, and drying at 100° . SnSe prepared by ppg. is soluble in alkali solution; the crystals prepared by heating Se with SnCl_2 are insoluble, even in boiling alkali solutions. Both crystalline and amorphous SnSe are soluble in solutions of alkali sulphides or selenides. SnSe is insoluble in HClAq ; oxidised by HNO_3Aq to $\text{SnO}_2 \cdot x\text{H}_2\text{O}$, H_2SeO_3 , and H_2SeO_4 . Heated with I, forms SnI_2 and SnSe_2 ; or, with an excess of I, SnI_2 and Se; reacts similarly with Br. SnSe is not reduced by heating in H. Heated in air it is gradually oxidised to SnO_2 and SeO_2 (S., *l.c.*). According to Ditte (*C. R.* 96, 1790), SnSe can be sublimed in a stream of H at a red heat; D. says S.G. is 6.179 at 0° .

STANNIC SELENIDE SnSe_2 . (*Tin disselenide*.) Mol. w. unknown. Not formed by heating together tin and Se, as excess of Se over that required to form SnSe sublimes; Little's statement that SnSe_2 is formed by directly combining tin and Se by heat (*A.* 112, 213) is probably wrong (Schneider, *P.* 127, 624). Prepared by rubbing 5 pts. I and 8 to 10 pts. crystallised SnI_2 (the SnI_2 is used to enable the I to be thoroughly powdered), adding 4 pts. powdered SnSe , then sufficient CS_2 to form a pasty mass (stirring constantly), and then adding more CS_2 to dissolve SnI_2 , and washing with CS_2 , when SnSe_2 remains as a dark, red-brown, indistinctly crystalline powder, which becomes darker when dried at 100° (Schneider, *l.c.*). S.G. 4.85. According to Welsmann (*A.* 116, 122), SnSe_2 is obtained, as a dark reddish-brown powder, by passing H_2Se into SnCl_2Aq ; heated in H, this powder gives off Se and leaves SnSe .

SnSe_2 is not acted on by water, or by dilute acids; it is slowly attacked by conc. boiling HClAq ; *aqua regia*, or conc. HNO_3Aq , oxidises it to SnO_2 , H_2SeO_3 , and H_2SeO_4 ; it dissolves in hot conc. H_2SO_4 , and when the olive-green solution is poured into water Se separates and $\text{Sn(SO}_4)_2$ remains dissolved. SnSe_2 is easily soluble in caustic alkali solutions, including NH_4Aq , forming blood-red liquids. Heated with I , in the ratio $\text{SnSe}_2:4\text{I}$, SnI_2 and Se are formed; Br reacts similarly to I (Schneider, *l.c.*).

Tin, silicides of. No definite compound has been isolated. Substances which seem to be of the nature of alloys are formed by heating together tin and Si ; treatment with HClAq dissolves tin from these bodies, and separates Si along with SiO_2 (v. Winkler, *J. pr.* 91, 193).

Tin, silicofluoride. According to Berzelius (*Lehrbuch* [5th ed.] 3, 767), the salt SnSiF_6 separates (?) from solution of $\text{SnO}_2 \cdot x\text{H}_2\text{O}$ in $\text{H}_2\text{SiF}_6\text{Aq}$ in prismatic crystals, which are readily crystallised from water.

Tin, sulphides of. Two sulphides of tin are known, SnS and SnS_2 ; the former is readily obtained by heating tin and S ; the latter by heating tin with an excess of S and some substance (e.g. NH_4Cl) which readily volatilises, and so removes heat, which would else drive off the S above that required to form SnS . Both sulphides are also formed by ppn. by H_2S from corresponding salts in solution. Both sulphides dissolve in solutions of alkali polysulphides, forming *thiostannates*, M_2SnS_3 .

STANNOUS SULPHIDE SnS . (*Tin monosulphide* or *protosulphide*.) Mol. w. unknown.

Preparation.—1. Finely divided tin is heated with c. equal parts of S ; the product is powdered, and repeatedly heated with S in a closed vessel. Ditte (*C. R.* 96, 1790) recommends to sublime the SnS thus prepared, by heating to redness in a porcelain tube in a stream of H .—2. H_2S is passed into a solution of a stannous salt until the liquid smells strongly of H_2S ; the brownish black pp. of amorphous SnS is washed and dried, and is then added, little by little, to molten SnCl_2 , as long as it is dissolved thereby; after cooling, SnCl_2 is dissolved out by dilute HClAq , and any dark-brown powder that is present is washed away from the heavier, greyish, lustrous, crystalline particles of SnS (Schneider, *P.* 95, 167).

Properties.—A dark, lead-grey, crystalline solid; S.G. 4.85° (Karsten, *S.* 65, 394), 5.27 (Boullay, *A. Ch.* [2] 43, 266). Ditte (*l.c.*) describes SnS , after sublimation in H , as crystallising in thin, lustrous squares with an angle of c. 90°; with a grey-blue, metal-like lustre; soft and friable; S.G. 5.0802 at 0°. Crystalline SnS melts at a red heat; it expands considerably on cooling (Ditte, *l.c.*). Prepared by ppn. SnS is a brownish-black, amorphous solid.

Reactions.—1. SnS , prepared by heating together tin and S , may be sublimed in *hydrogen* at a red heat (Ditte, *C. R.* 96, 1790); but continued heating in H is said to reduce it to tin, H_2S being given off.—2. Heated in *air* SnS is gradually converted into SnO_2 and SO_2 .—3. Reacts with *chlorine*, even at the ordinary temperature, to form SnCl_2 and $\text{SnCl}_4 \cdot 2\text{SnCl}_2 = (\text{Sn}_2\text{Cl}_4)_2$ (H. Rose, *P.* 47, 517).—4. Fusion with *potassium cyanide* produces tin and KCN .—5. SnS dis-

solves gradually in boiling *hydrochloric acid*, forming SnCl_2 solution and giving off H_2S (for details of interaction with HClAq of different concentration, and with HCl gas, v. Ditte, *C. R.* 97, 42).—6. Gradually oxidised to SnO_2 by heating with *nitric acid*.—7. Dissolves in solutions of *alkali polysulphides*, forming alkali thiostannates M_2SnS_3 .—8. SnS is generally said to be nearly insoluble in solutions of *alkali monosulphides* (M_2S). According to Ditte (*C. R.* 94, 1419, 1470), SnS is not acted on by K_2SAq at the ordinary temperature if the concentration of the solution does not exceed $20\text{K}_2\text{S}:100\text{H}_2\text{O}$; but a more conc. solution of K_2SAq , out of contact with air, gradually converts the SnS into a grey, spongy mass of tin; and still more conc. K_2SAq dissolves this, forming $\text{K}_2\text{SnS}_3\text{Aq}$ and giving off H : if air is admitted the reactions are more complex.

STANNIC SULPHIDE SnS_2 . (*Tin disulphide*.) Mol. w. not known.

Preparation.—1. By saturating SnCl_2Aq containing a little HClAq with H_2S , warming, again saturating with H_2S , warming gently for some hours, collecting the pp., washing with dilute H_2SAq , drying, and heating to above 100° out of contact with air. Pure SnS_2 can scarcely be prepared in this way; there seems to be always some $\text{SnO}_2 \cdot x\text{H}_2\text{O}$ present in the pp. (Kühn, *A.* 84, 110; Barfoed, *J. pr.* 101, 368).—2. By passing the mixed vapours of SnCl_2 and H_2S through a red-hot porcelain tube, or by passing H_2S into SnCl_2 and heating the white crystals of $\text{SnCl}_4 \cdot 5\text{H}_2\text{S}$ so obtained (Coldridge, *P. M.* [5] 29, 383).—3. A mixture of finely-divided tin and S , or of SnS and S , with some substance that gradually volatilises and so removes heat, is slowly heated to redness in a glass retort, or a loosely covered flask, imbedded in sand; the volatile substance gradually passes off, then the excess of S is volatilised and the SnS_2 remains, partly on the sides and partly on the bottom of the vessel. If tin is heated with S only, the heat produced in the reaction is so great that the SnS_2 formed is resolved into SnS and S . Various mixtures have been employed by different chemists; the following give good results: (1) equal parts sifted tin-filings, S , and NH_4Cl (Pelletier); (2) 4 parts tin-filings, 3 parts S , 2 parts NH_4Cl (Woulfe); (3) a pulverised amalgam of 12 parts tin and 6 parts Hg , with 7 parts S , and 6 parts NH_4Cl (W.); (4) 5 parts SnS and 8 parts HgCl_2 (W.).

References.—Pelletier (*Crell's Chem. Ann.* 1797 [1] 46); Woulfe (*ibid.* 1, 149); Bullion (*ibid.* 1793 [1] 89); Proust (*Gehlen's Journ. f. Chem. und Phys.* 1, 250).

According to Gmelin (*Handbuch* [5th ed.] 3, 75) if NH_4Cl is heated with tin and S there is formed a compound of NH_4Cl and SnCl_2 , which then interacts with the S , forming SnS_2 ($?2\text{Sn} + 8\text{NH}_4\text{Cl} = 2(2\text{NH}_4\text{Cl} \cdot \text{SnCl}_2) + 2\text{H}_2 + 4\text{NH}_3$; $2(2\text{NH}_4\text{Cl} \cdot \text{SnCl}_2) + 2\text{S} = \text{SnS}_2 + 2\text{NH}_4\text{Cl} \cdot \text{SnCl}_2 + 2\text{NH}_3\text{Cl}$).

Properties.—Prepared by sublimation, SnS_2 is a soft golden-yellow, lustrous, crystalline solid; S.G. 4.6 (Karsten, *S.* 65, 394), 4.42 (Boullay, *A. Ch.* [2] 43, 266). Crystalline SnS_2 is known as *mosaic gold* (v. DICTIONARY OF APPLIED CHEMISTRY, vol. iii. p. 845).

Reactions and Combinations.—1. Heated in a closed vessel gives SnS and S , and a sublimate

of SnS_2 .—2. Heated in air SnO_2 and SO_2 are formed.—3. Chlorine liquefies SnS_2 , on cooling yellow crystals of $\text{SnCl}_2 \cdot 2\text{SnCl}_4$ are formed (H. Rose, P. 42, 517).—4. The compound $\text{SnS}_2 \cdot \text{I}_2$ ($=\text{SnS}_2 \cdot \text{SnI}_4$) is said to be formed by heating SnS_2 with iodine in a stream of CO_2 (Schneider, J. pr. 79, 419; v. also TIN, THIO-ROXIDES, *infra*). According to Schneider (l.c.) a boiling alcoholic solution of I does not act on SnS_2 prepared by sublimation, but with amorphous SnS_2 prepared by ppt. it gives $\text{SnS}_2 \cdot \text{I}_2$.—5. Amorphous, but not crystalline, SnS_2 is slowly decomposed by boiling conc. hydrochloric acid, H_2S being given off and SnCl_4 solution formed.—6. The amorphous sulphide is slowly oxidised by hot nitric acid; aqua regia oxidises both amorphous and crystalline SnS_2 to SnO_2 and H_2SO_4 .—7. Fusion with lead monoxide produces a mixture of sulphides and oxides of tin and lead; with excess of PbO , SO_2 is given off and lead remains.—8. SnS_2 was said by Dumas (S. 66, 409) to combine with stannic chloride, forming $\text{SnS}_2 \cdot 2\text{SnCl}_4$; the compound being produced by the interaction of SnCl_4 and H_2S . According to Coldridge (P. M. [5] 29, 383) this compound does not exist, the product of the reaction being $\text{SnCl}_4 \cdot 5\text{H}_2\text{S}$.—9. SnS_2 dissolves in alkali sulphide solutions, forming thioannates (*q. v.*, *infra*), M_2SnS_3 .—10. In alkali solutions SnS_2 dissolves, probably forming stannates and thioannates ($? 3\text{SnS}_2 + 6\text{KOH} \cdot \text{Aq} = \text{K}_2\text{SnO}_3 \cdot \text{Aq} + 2\text{K}_2\text{SnS}_3 \cdot \text{Aq} + 3\text{H}_2\text{O}$).

TIN SESQUISULPHIDE. Berzelius (Lehrbuch [5th ed.] 2, 600) gave the formula Sn_2S_3 to a greyish-yellow, lustrous solid obtained by heating a mixture of 3 parts SnS and 1 part S in a retort; the substance was almost certainly a mixture of SnS and SnS_2 .

Tin, sulphochlorides of; v. TIN THIO-CHLORIDES, *infra*.

Tin, sulpho-iodide of; v. TIN THIO-IODIDE, *infra*.

Tin, sulphocyanide of; v. vol. ii. p. 352.

Tin, telluride of, SnTe . A grey, lustrous, metal-like, crystalline solid; S.G. 6.478 at 0° ; obtained by heating together tin and Te, and slowly subliming in a stream of H (Ditte, C. R. 96, 1790).

Tin, thio-acids and salts of. It is doubtful whether a thio-acid of tin has been isolated with certainty; a few salts derived from the acid H_2SnS_3 have been obtained.

THIOSTANNIC ACID. (Sulphostannic acid.) Kühn (A. 84, 110) obtained an olive-brown pp. by adding HClAq or $\text{H}_2\text{O}_2 \cdot \text{Aq}$ to a conc. solution of $\text{Na}_2\text{SnS}_3 \cdot \text{Na}_2\text{S} \cdot 12\text{H}_2\text{O}$ (*v. infra*); after washing, and drying at 100° , the pp. was a leaden-grey, lustrous solid having the composition H_2SnS_3 . Storch (M. 10, 255), repeating Kühn's experiments, always obtained brown pps., which did not contain more S than required by the ratio $\text{Sn}:\text{S}=1:2.19$. S. concluded that the pps. were mixtures of H_2SnS_3 and SnS_2 . By adding dilute oxalic acid solution to solution of Na_2SnS_3 (prepared by saturating $\text{Na}_2\text{SnO}_3 \cdot \text{Aq}$ with H_2S) in quantity just sufficient to combine with the Na present, S. (l.c.) obtained a deep-yellow liquid which remained clear for hours; after removing the H_2S by a current of air S. found that the liquid contained tin and S in the ratio $\text{Sn}:\text{S}$; he concluded that H_2SnS_3 was pre-

sent in the liquid. The liquid was decolourised by NH_4Aq , $\text{KOH} \cdot \text{Aq}$, $\text{Na}_2\text{CO}_3 \cdot \text{Aq}$, $(\text{NH}_4)_2\text{CO}_3 \cdot \text{Aq}$, and NH_4ClAq ; strong acids gave brownish pps. containing rather more S than required by the formula SnS_2 .

THIOSTANNATES (Kühn, l.c.; Höring, Hirsch's Zeit. für Pharm. 1851, No. 8). The alkali salts are obtained by dissolving SnS_2 in alkali sulphide solutions, M_2SAq ; the alkaline earth salts are formed by double decomposition from the alkali salts.

Potassium thioannate $\text{K}_2\text{SnS}_3 \cdot 10\text{H}_2\text{O}$. Obtained by dissolving SnS_2 in K_2SAq , and adding alcohol, when the salt separates as a dark brown heavy oil; all H_2O is given off at 100° .

Sodium thioannates. The normal salt $\text{Na}_2\text{SnS}_3 \cdot 2\text{H}_2\text{O}$ is obtained, in yellow, glassy, regular crystals, by adding tin, little by little, to molten Na_2S , treating the fused mass with water, and evaporating at a low temperature. A solution of SnS and S in NaSAq deposits colourless, monoclinic crystals of the basic salt, which, when dried over H_2SO_4 , has the composition $\text{Na}_2\text{SnS}_3 \cdot \text{Na}_2\text{S} \cdot 12\text{H}_2\text{O}$. The stronger acids (HCl , H_2SO_4 , $\text{CHCl}_3 \cdot \text{CO}_2\text{H}$) ppt. SnS_2 at once from $\text{Na}_2\text{SnS}_3 \cdot \text{Aq}$; but weak acids (H_3PO_4 , $\text{H}_2\text{C}_2\text{O}_4$, $\text{CH}_3\text{Cl} \cdot \text{CO}_2\text{H}$, &c.) form brown-yellow solutions from which red-brown pps. separate more or less slowly (Storch, M. 10, 255). Kühn (l.c.) gives the reactions of the two Na thioannates with solutions of several metallic salts; many of the pps. were doubtless thioannates of the metals employed.

PLATINO-THIOSTANNATES. Schneider (Z. [2] 5, 629; 6, 270, 613) obtained salts to which he gave the composition $\text{M}_2\text{Pt}_2\text{SnS}_3$ ($=\text{M}_2\text{S} \cdot 3\text{PtS} \cdot \text{SnS}_2$), where $\text{M}=\text{K}$ or Na , by fusing SnS , Pt , M_2CO_3 , and S, and lixiviating with water.

Tin, thiochlorides of. A compound $\text{SnS}_2 \cdot \text{Cl}_2$ ($=\text{SnCl}_4 \cdot 2\text{SnCl}_2$) is said to be formed, along with SnCl_4 , by the interaction of Cl and SnS or SnS_2 (H. Rose, P. 42, 517). Dumas (S. 66, 409) described a compound $\text{Sn}_2\text{S}_3 \cdot \text{Cl}_2$ ($=\text{SnS}_2 \cdot \text{SnCl}_2$) as obtained by passing H_2S into SnCl_4 ; but according to Coldridge (P. M. [5] 29, 383) this compound is not formed. C. (l.c.) says that the passage of H_2S into SnCl_4 produces white crystals of $\text{SnCl}_4 \cdot 5\text{H}_2\text{S}$, which are decomposed by heat, giving off HCl and H_2S , and leaving SnS_2 .

Tin, thio-iodide of. By melting together crystalline SnS_2 and I, in the ratio $\text{SnS}_2:4\text{I}$, allowing the liquid to cool, and either heating in a stream of CO_2 , or dissolving in CS_2 and crystallising, Schneider (J. pr. 79, 419) obtained brown, lustrous crystals of $\text{SnS}_2 \cdot \text{I}_2$ ($=\text{SnS}_2 \cdot \text{SnI}_4$). This thio-iodide is dissolved unchanged by CS_2 , or CHCl_3 ; alcohol separates S; water, or a solution of a caustic alkali, produces SnS_2 , S, and HIAq (or MIAq); HClAq or $\text{HNO}_3 \cdot \text{Aq}$ decomposes it, with separation of S. The compound $\text{SnS}_2 \cdot \text{I}_2$ is also produced by the interaction of a solution of I in CS_2 and ppt., dried SnS_2 (S., l.c.). M. M. P. M.

TIN ORGANIC COMPOUNDS.

Stannic methide SnMe_4 . (78°). S.G. 1.313. V.D. 6.00 (calc. 6.15). Got by heating an alloy of tin and sodium (14 p.c.) with MeI ($\frac{2}{3}$ pt.) at 100° – 120° (Ladenburg, A. Suppl. 8, 74; cf. Cahours, A. 111, 236; 114, 372). Oil, with ethereal odour. Reduces alcoholic AgNO_3 ,

Stannic tri-methylo-iodide SnMe_3I . (170°). S.G. $\frac{2}{2}$ 2.148. Formed by the action of I on SnMe_3 . Oil. Yields crystalline SnMe_3OH and the salts $(\text{SnMe}_3)_2\text{SO}_4$, $\text{SnMe}_3\text{O.CO.H}$, and SnMe_3OAc . Forms the compounds SnMe_3OEt (Ladenburg, B. 3, 358) and $\text{SnMe}_3\text{I}2\text{NH}_3$ (Cahours, A. 122, 56).

Stannic di-methylo-di-iodide SnMe_2I_2 . [30°]. (228°). S.G. $\frac{22}{2}$ 2.872. Formed by heating tin foil with MeI at 150° (C.). Monoclinic crystals (from ether-alcohol). Converted by ammonia into amorphous SnMe_2O , which is insol. water, but dissolves in acids forming the following crystalline salts: SnMe_2Cl_2 [90°] (159°), forming trimetric crystals; $a:b:c = .834:1: .941$.— $\text{SnMe}_2\text{PtCl}_4$ 7aq, forming trimetric crystals; $a:b:c = .888:1: .977$.— SnMe_2Br_2 . (209°).— SnMe_2SO_4 , forming monoclinic crystals (Hjortdahl, C. R. 88, 584).

Stannic ethide SnEt_4 . Mol. w. 234. (181°). S.G. $\frac{23}{2}$ 1.187. Formed from SnEt_3I , and EtI (Buckton, A. 109, 218; 112, 223; Frankland, A. 111, 44). Formed also, together with tin and ZnEtCl , by adding fused SnCl_2 to cooled ZnEt_2 , and then distilling (Frankland & Lawrence, C. J. 35, 134). Prepared by heating powdered tin with EtI and the zinc-copper couple; and also by heating ZnEtI with powdered tin at 160° (Letts & Collie, C. J. Proc. 2, 166). Oil. Has no action at 180° on Al, Na, or Mg. Slowly absorbs sulphur dioxide, forming crystalline $\text{SO}_2(\text{OSnEt}_4)_2$, insol. ether and an oil $\text{SnEt}_4\text{SO}_4\text{Et}$, sol. ether. Hot conc. HClAq forms ethane and SnEt_3Cl . Iodine forms SnEt_3I and IEt .

Stannous ethide SnEt_2 . S.G. $\frac{15}{2}$ 1.558. Formed by adding zinc to a warm solution of SnEt_2Cl_2 (Frankland). Oil. Decomposed at 150° into SnEt_4 and tin. Br forms SnEt_2Br_2 .

Distannic hexa-ethide Sn_2Et_6 . (265°–270°). S.G. $\frac{2}{2}$ 1.412. V.D. 14.8 (calc. 14.7). Got by distilling SnEt_3I with sodium (Ladenburg, A. Suppl. 8, 66; B. 3, 647). Pungent oil. I forms SnEt_3I . Conc. HClAq forms SnEt_2Cl_2 , ethane, and hydrogen.

Stannic tri-ethylo-iodide SnEt_3I . (231°). S.G. $\frac{22}{2}$ 1.833. Formed by the action of EtI on an alloy of tin and sodium (Ladenburg, A. Suppl. 8, 60; B. 3, 353, 647; cf. Löwig, A. 84, 308). Liquid. Combines with NH_3 (2 mols.). On distilling with KOHAc it yields SnEt_3OH crystallising from ether in prisms [43°] (271°) converted by heat into oily $(\text{SnEt}_3)_2\text{O}$, which recombines with water forming the hydroxide. NaOEt converts the iodide into SnEt_3OEt (191°) S.G. $\frac{2}{2}$ 1.263, which is at once changed by water into the hydroxide. The hydroxide SnEt_3OH is sol. water, strongly alkaline, absorbs CO_2 from the air, and is converted by acids into the salts:— SnEt_3Cl . [c. 0°]. (209°). S.G. $\frac{2}{2}$ 1.428.— $(\text{SnEt}_3)_2\text{PtCl}_6$.— $\text{SnEt}_3\text{ITl}_3$.— SnEt_3Br . (228°) (Cahours).— SnEt_3Cy .— SnEt_3CyO .— SnEt_3NO_2 .— $(\text{SnEt}_3)_2\text{SO}_4$. Hexagonal prisms terminated by pyramids (Hjortdahl).— $(\text{SnEt}_3)_2\text{S}$.— SnEt_3SH .— $(\text{SnEt}_3)_2\text{H}_2\text{PO}_4$.— SnEt_3OAc .— SnEt_3OBz .— $(\text{SnEt}_3)_2\text{CO}_2$.— $(\text{SnEt}_3)_2\text{C}_2\text{O}_4$ aq. — Formate $(\text{SnEt}_3)_2\text{CHO}_2$.—Butyrate $(\text{SnEt}_3)_2\text{C}_4\text{H}_7\text{O}_2$.—Tartrates $(\text{SnEt}_3)_2\text{C}_4\text{H}_4\text{O}_6$ aq.— $(\text{SnEt}_3)_2\text{HC}_2\text{H}_3\text{O}_4$ aq.

Stannic di-ethylo-di-iodide SnEt_2I_2 . [44.5°]. (245°). Formed from tin and EtI by exposure

to sunlight or by heating with EtI at 150° (Frankland, A. 85, 329; Löwig, A. 84, 308; Cahours & Riche, A. 84, 333). Needles (from alcohol), sl. sol. cold water. May be sublimed. Alcoholic NH_3 forms SnEt_3O , which is an amorphous powder, insol. water, converted by acids into the following salts: SnEt_2Cl_2 . [85°]. (220°), forming trimetric crystals; $a:b:c = .839:1: .943$.— $\text{SnEt}_2\text{Cl.OH}$: plates.— SnEt_2Br_2 . (233°). V.D. 11.6 (calc. 11.7).— $\text{SnEt}_2(\text{NO}_3)_2$.— SnEt_2ICy .— $\text{SnEt}_2(\text{SCy})_2$.— SnEt_2S .— SnEt_2SO_4 .—Crystals. $\text{SnEt}_2(\text{OAc})_2$.— $\text{SnEt}_2\text{C}_2\text{O}_4$.—Formate $\text{SnEt}_2(\text{CHO}_2)_2$.

Stannic ethylo-trimethide SnEtMe_3 . (125°–128°). Formed from SnMe_3I and ZnEt (Cahours, A. 122, 59). Oil; converted by I into EtI and SnMe_3I .

Stannic di-ethylo-di-methide SnEt_2Me_2 . (145°). S.G. $\frac{2}{2}$ 1.260. V.D. 6.84 (calc. 7.14). Formed from SnEt_3I , and ZnMe_2 (Frankland, A. 111, 50; Morgunoff, A. 144, 157). Oil.

Stannic methylo-tri-ethide SnMeEt_3 . (163°). V.D. 6.72 (calc. 6.65). Formed from SnEt_3I and ZnMe_2 in the cold (C.). Heavy oil.

Stannic tetrapropylide SnPr_4 . (224°). S.G. $\frac{15}{2}$ 1.179. Formed from SnPr_3I and ZnPr_2 (Cahours, C. R. 76, 138). Pungent oil.

Stannic tripropylo-iodide SnPr_3I . (261°). S.G. $\frac{15}{2}$ 1.692. Formed from PrI and an alloy of Na and tin (Cahours & Demaray, C. R. 88, 725, 1112). Oil, converted by moist Ag_2O into crystalline SnEt_3OH .

Stannic di-propylo-di-iodide SnPr_2I_2 . (272°). Formed from tin and PrI . Oil. Converted by alkalis into amorphous SnPr_2O , insol. water, which yields SnPr_2Cl_2 [81°].

Stannic tri-isopropylo-iodide SnPr_3I . (257°). Got in like manner.

Stannic di-isopropylo-di-iodide SnPr_2I_2 . (267°). Yields SnPr_2Cl_2 [57°].

Stannic tri-isobutylo-iodide $\text{Sn}(\text{C}_4\text{H}_9)_3\text{I}$. (285°). S.G. $\frac{15}{2}$ 1.540. Formed from CH_3PrI and a 9 p.c. alloy of Na in tin (Cahours & Demaray, C. R. 89, 68). Pungent oil, converted by KOH into $\text{Sn}(\text{C}_4\text{H}_9)_3\text{OH}$ (313°).

Stannic di-isobutylo-di-iodide $\text{Sn}(\text{C}_4\text{H}_9)_2\text{I}_2$. (290°–295°). Formed by heating tin foil with isobutyl iodide at 125°. Liquid, converted by alkalis into amorphous $\text{Sn}(\text{C}_4\text{H}_9)_2\text{O}$, and by HCl into $\text{Sn}(\text{C}_4\text{H}_9)_2\text{Cl}_2$ [c. 6°] (261°).

Stannic tetra-isoamylo-iodide $\text{Sn}(\text{C}_5\text{H}_{11})_4\text{I}$. Formed from isoamyl iodide and an alloy of Na (1 pt.) and tin (6 pts.) (Grimm, A. 92, 383). Liquid.

Stannic tri-isoamylo-iodide $\text{Sn}(\text{C}_5\text{H}_{11})_3\text{I}$. (304°). Accompanies the preceding compound (C. a. D.). Converted by potash into oily $\text{Sn}(\text{C}_5\text{H}_{11})_3\text{OH}$ (337°).

Stannic tetraphenylide SnPh_4 . [226°]. (over 420°). Formed by heating bromo-benzene with a tin-sodium alloy and acetic ether (Polis, B. 22, 2915). Colourless prisms, insol. ligroin, v. sl. sol. alcohol, v. sol. boiling benzene.

Stannic tri-phenylo-chloride SnPh_3Cl . [105°]. Formed by the action of NaNO_2 on a solution of SnPh_3Cl in HOAc , the yield being 85 p.c. of that represented by the equation $3\text{SnPh}_3\text{Cl} = 2\text{SnPh}_3\text{Cl} + \text{SnCl}_4$ (Aronheim, B. 12, 509). Converted by potash into SnPh_3OH 1½ aq [118°].

Stannic di-phenylo-dichloride SnPh_2Cl_2 . [42°]. (335°). Prepared by boiling HgPh_2 with SnCl_4 and ligroin (Aronheim, B. 10, 2229;

11, 2285; A. 194, 145). Triclinic prisms; $a:b:c=588:1:067$; $\alpha=62^\circ 47'$; $\beta=76^\circ 48'$; $\gamma=94^\circ 8'$. Sol. alcohol and ligroin, miscible with ether. Converted by means of water into $\text{SnPh}_2\text{Cl.OH}$, an amorphous insoluble powder [187°]. Potash forms SnPh_2O . Ether, alcohol, and sodium-amalgam form $\text{SnPh}_2(\text{OEt})_2$ [124°].

Stannic di-phenyl-di-bromide SnPh_2Br_2 [c. 38°]. (230° at 42 mm.). Formed from SnPh_2 and Br (Polis), and from the oxide and HBr (A.).

Stannic di-phenyl-chloro-bromide SnPh_2BrCl [39°]. Crystalline. Formed from $\text{SnPh}_2\text{Cl}(\text{OH})$ and HBr .

Stannic di-phenyl-chloro-iodide SnPh_2ClI . [69°]. Yellow monoclinic crystals (from ether), decomposed by water.

TIN GROUP OF ELEMENTS. Group IV. in the periodic classification of the elements contains the following members:—

Even series	2	4	6	8	10	12
	C	Ti	Zr	Ce	—	Th
Odd series	3	5	7	9	11	
	Si	Ge	Sn	—	Pb	

Subdividing this group in accordance with the chemical similarities of the elements we get the following families:—

Carbon family: C and Si.

Titanium family: Ti, Zr, Ce, —, Th.

Tin family: Ge, Sn, —, Pb.

The *carbon family* is considered in the article CARBON GROUP OF ELEMENTS (vol. i. p. 682); and that article also gives a sketch of the chemical relations of all the members of the group. The elements of the *titanium family* are considered under the heading TITANIUM GROUP OF ELEMENTS (this vol., p. 749). The *tin family* is considered in the present article.

Ge occurs in small quantities, as sulphide, in a very few rare minerals. Tin and lead are found native in not very large quantities. The chief ore of tin is *tinestone*, which contains SnO_2 ; SnS_2 is also found in *tin pyrites*; and various *micas* contain more or less SnO_2 . *Galena*, containing PbS, is the chief ore of lead; sulphate, carbonate, phosphate, &c., are also found in considerable quantities. Ge is obtained by heating its ore with Na_2CO_3 and S, dissolving in water, decomposing Na_2S by H_2SO_4 , ppg. Ag (Ag_2S is a constituent of the ore) by HClAq , then ppg. GeS_2 by H_2S , oxidising the GeS_2 to GeO_2 by HNO_3 , and reducing the GeO_2 by heating in H or with C. Tin is obtained by calcining *tinestone*, washing, and reducing the SnO_2 by heating with C. To obtain lead, *galena* is roasted in such a quantity of air that it is partially oxidised, both PbO and PbSO_4 being formed; by then heating out of contact with much air the PbS, PbO, and PbSO_4 interact to form SO_2 and lead. Tin and lead have been known from very early times. Ge was isolated in 1885.

The table on page 736 presents some of the principal physical and chemical properties of the tin elements.

General formulæ and characters of compounds. Oxides:— MO , MO_2 ; also Pb_3O_4 and Pb_2O_3 ; various hydrates of most of these oxides are known. Sulphides:— MS , MS_2 (? PbS_2). Haloid compounds:— MX_2 and MX_4 . Acids:— H_2MX_2 , where $\text{M}=\text{Ge}$ or Sn , and $\text{X}=\text{either Br, Cl, F, or I}$; also H_2PbI_2 ; H_2SnO_2

and $\text{H}_2\text{H}_2\text{Sn}_2\text{O}_4$; ? H_2SnS_2 . Salts:— MX_2 and MX_4 , where $\text{M}=\text{Sn}$ or Pb and $\text{X}=\text{NO}_3$, $\frac{1}{2}\text{SO}_4$, $\frac{1}{3}\text{PO}_4$, &c. Salts containing M in the acidic radiol:— R^1MX_2 , where $\text{M}=\text{Ge}$, Sn , (? Pb), and X is a halogen; R^1MO_2 , where $\text{M}=\text{Sn}$, or Pb ; also R^1PbO_2 ; also $\text{R}^2\text{H}_2\text{Sn}_2\text{O}_4$; also R^2SnS_2 .

The *oxides* MO are basic; they react with acids to form salts MX_2 , $\text{X}=\text{NO}_3$, $\frac{1}{2}\text{SO}_4$, $\frac{1}{3}\text{PO}_4$, &c. (no salts of GeO have yet been isolated). PbO also dissolves in molten KOH , forming K_2PbO_2 . The *oxides* MO_2 , where $\text{M}=\text{Sn}$ or Pb , are both basic and acidic; they react with some acids to form salts MX_4 ; several of these salts have been isolated when $\text{M}=\text{Sn}$, very few when $\text{M}=\text{Pb}$: they also react with molten KOH or NaOH ($\text{SnO}_2 \cdot x\text{H}_2\text{O}$ also with MOHAq) to form salts $\text{K}_2(\text{orNa})_2\text{MO}_4$; when $\text{M}=\text{Sn}$ two classes of salts are known, *stannates* M_2SnO_6 , and *metastannates*, probably $\text{M}_2\text{H}_2\text{Sn}_2\text{O}_{10}$. GeO_2 dissolves in acids, also in molten KOH or K_2CO_3 , but the products of these reactions have not yet been examined. Pb_2O_3 reacts with dilute strong acids to form PbO_2 and PbX_2 , which dissolves; with glacial acetic acid Pb_2O_3 forms $\text{Pb}(\text{C}_2\text{H}_3\text{O}_2)_2$ and $\text{Pb}(\text{C}_2\text{H}_3\text{O}_2)_4$. Pb_2O_3 probably reacts with dilute strong acids to give PbO , and a salt of PbO . The hydrates of MO and MO_2 react similarly to the oxides. Some of the hydrates $\text{SnO}_2 \cdot x\text{H}_2\text{O}$ are acidic; one class of these is probably polymeric with the other. There are indications of the existence of an oxide MO_3 in the case of tin; this oxide seems to be acidic.

The *sulphides* of Ge have not been much investigated; GeS_2 dissolves in alkali sulphide solutions, and is probably acidic. GeS has been gasified and V.D. determined. The sulphides of tin are both basic and acidic; with hot conc. HClAq they give SnCl_2 and SnCl_4 respectively; both dissolve in alkali sulphide solutions to form *thiostannates* M_2SnS_3 . PbS is basic; with acids it gives salts PbX_2 , and H_2S ; there are indications of the existence of a higher sulphide, perhaps PbS_2 , which will probably form thioplumbates with the sulphides of strongly positive metals.

The *haloid compounds* MX_2 (none isolated yet when $\text{M}=\text{Ge}$) may be formed by the direct union of the elements, and by the other usual methods. SnCl_2 and PbCl_2 have been gasified, and the formulæ are molecular; molecules of the composition Sn_2Cl_4 probably exist, but are decomposed at c. the boiling-point of the compound. Several salts are known of the form M_2SnX_4 , where $\text{X}=\text{Br}$, Cl , F , or I ; and an acid $\text{HSnCl}_2 \cdot x\text{H}_2\text{O}$ and some salts MSnI_2 are also said to exist. HPbI_2 and salts MPbI_2 have been isolated; and also several salts coming under the general formula $x\text{PbX}_2 \cdot y\text{NH}_4\text{Cl}$, where $\text{X}=\text{Br}$ or Cl . The haloid compounds MX_4 have been gasified, and V.D.s determined, when $\text{M}=\text{Ge}$ and $\text{X}=\text{Cl}$ or F , and when $\text{M}=\text{Sn}$ and $\text{X}=\text{Br}$ or Cl . PbCl_4 has not been isolated with certainty, but salts of the form M_2PbCl_4 are known, and also some salts $x\text{PbCl}_4 \cdot y\text{NH}_4\text{Cl}$. The acids H_2GeF_6 , H_2SnBr_6 , and H_2SnCl_6 have been obtained, and also salts derived from these acids; salts M_2SnF_6 and M_2PbCl_6 are also known. GeHCl_4 has been isolated. Many *oxyhaloid compounds* $x\text{MO} \cdot y\text{MX}_2$ and $x\text{MO}_2 \cdot y\text{MX}_2$ are known.

The *oxyacids* of tin, H_2SnO_2 , and (probably) $\text{H}_2\text{H}_2\text{Sn}_2\text{O}_4$, are to be classed with the weak

	GERMANIUM.	TIN.	LEAD.
<i>Atomic weights.</i>	72.3	118.8	206.4
One or more compounds of each element have been gasified. Specific heats have also been determined directly. There is some evidence in favour of the conclusion that the molecules of tin and lead, in solution in Hg, are monatomic.			
<i>Melting-points. (approx.).</i>	900°	232°	330°

<i>Atom. wts.</i>	13.2	16.3	18.1
<i>Spec. gravs. (approx.).</i>			
<i>Occurrence and preparation.</i>	Double sulphide of Ge and Ag occurs as a rare mineral. GeO ₂ also found in some specimens of <i>euxenite</i> , with oxides of Nb, Ta, and Y. Prepared by reducing GeO ₂ by H or C.	Metal found in small quantities. SnO ₂ occurs in tolerable quantities widely distributed. Prepared by reducing SnO ₂ by C.	Small quantities of lead found. Chief ore contains PbS; widely distributed in considerable quantities. Prepared by interaction of PbS, PbO, and PbSO ₄ ; also by reducing PbO by C.
<i>Physical properties.</i>	Greyish white, lustrous, very brittle. Crystallises in regular octahedra. Melts at c. 900°; slightly volatilised at 1,850° in N or H.	Silver-white, lustrous, malleable, but malleability varies with temperature; tenacity very small. Crystallises very easily in rhombic and quadratic forms. Melts easily (at 232°), and boils between 1,450° and 1,600°.	White, with tinge of blue; lustrous; very malleable and ductile; tenacity very small; very soft. Crystallises easily in regular octahedra. Melts easily (at 330°), but at higher temperature than tin, and boils between 1,450° and 1,600°.
<i>Chemical properties.</i>	Unchanged in air at ordinary temperature; oxidised to GeO ₂ when heated in fine division. Combines readily with Br, Cl, and I when heated, forming GeX ₄ . Heated in HCl gas forms GeHCl ₄ . Dissolves in H ₂ SO ₄ . No salts have yet been isolated by replacing H of oxyacids by Ge. GeO ₂ dissolves in fused KOH or K ₂ CO ₃ . H ₂ GeF ₆ . Aq and salts of this acid are known.	Unchanged in pure air at ordinary temperature. Heated in air gives SnO and SnO ₂ . Heated in Br, Cl, or I forms SnX ₄ and SnX ₂ . Heated with S forms SnS and SnS ₂ ; also forms SnSe and SnSe ₂ . Reacts with acids forming two series of salts, SnX ₄ and SnX ₂ , X = NO ₃ , $\frac{1}{2}$ SO ₄ , $\frac{1}{2}$ PO ₄ , &c. Conc. HNO ₃ produces SnO ₂ .xH ₂ O. SnO is basic; SnO ₂ .xH ₂ O both basic and acidic, with strong acids forms salts SnX ₄ , and with caustic alkalis forms stannates M ₂ SnO ₃ . SnS ₂ forms thio-stannates M ₂ SnS ₃ with alkali sulphides. Stannic fluorides M ₂ SnF ₆ are known; the acids H ₂ SnCl ₆ and H ₂ SnBr ₆ have been isolated. Mol. w. perhaps same as at. w. in solution in Hg. Valency of atom varies from 2 in SnCl ₂ gas to 4 in SnCl ₄ gas.	Tarnishes in air, film of oxide (? Pb ₂ O) forming on surface. Melted in air forms PbO and Pb ₂ O ₃ . Combines with halogens to form PbX ₂ ; PbCl ₂ also probably isolated. Combines with S and Se, forming PbS and PbSe; PbS.xS also probably exists. Reacts with acids forming salts PbX ₂ , X = NO ₃ , $\frac{1}{2}$ SO ₄ , $\frac{1}{2}$ PO ₄ , &c. PbO is basic; PbO ₂ feebly basic and feebly acidic; Pb(C ₂ H ₃ O ₂) ₂ has been isolated, and probably PbCl ₄ ; with molten KOH, PbO ₂ forms K ₂ PbO ₄ . No thioplumbates isolated. No acid H ₂ PbF ₆ or salts thereof, isolated; but 3KF.HF.PbF ₆ probably exists. Mol. w. perhaps same as at. w. in solution in Hg. Atom is divalent in gaseous molecule PbCl ₂ , and tetravalent in gaseous molecule PbMe ₄ .

acids; the one is probably a polymeride of the other. The salts of these acids show very distinct differences: the acids themselves interact with strong acids to form salts containing tin in the positive radicles. Of acids containing tin and halogens the following have (probably) been isolated: HSnCl_4 , H_2SnBr_4 , and H_2SnCl_4 . H_2GeF_6 is known, and H_2PbI_4 is said to exist. It is doubtful whether *thiostannic acid* H_2SnS_4 has been obtained pure, but salts of this acid have been isolated.

The salts of oxyacids containing these metals in the negative radicles are M_2SnO_4 and $\text{M}_2\text{H}_2\text{Sn}_2\text{O}_{11}$, M_2PbO_4 and M_2PbO_6 . These salts are generally easily decomposed. Oxyacids and salts of oxyacids of Ge have yet to be searched for.

Salts derived from oxyacids by replacing H by M are known when $\text{M} = \text{Sn}$ or Pb ; no Ge salts of oxyacids have yet been isolated. The tin salts belong to two classes, SnX_2 and SnX_4 , where $\text{X} = \text{NO}_2$, $\frac{1}{2}\text{SO}_4$, $\frac{1}{2}\text{PO}_4$, &c.; both classes of salts readily undergo decomposition and show a general tendency to separate off SnO or SnO_2 . Almost all the lead salts belong to the class PbX_2 ; they are more definite and less ready to split off oxide or decompose to basic salts than the corresponding salts of tin. $\text{Pb}(\text{C}_2\text{H}_3\text{O}_2)_2$ is the only lead salt of an oxyacid of the class PbX_4 that has been certainly isolated; it is decomposed by the least trace of moisture, giving a pp. of PbO_2 .

The elements of the tin family are distinctly metallic in their physical properties, and in most of their chemical properties also; they exhibit, however, non-metallic characters in their highest salt-forming oxides, MO_2 , which are acidic towards strong bases, while they also react as basic oxides towards several acids. The tin elements are less chemically metallic, on the whole, than the members of the even-series, or titanium family, of Group IV.; the two distinctly non-metallic elements of the group are the first member of the even series—carbon, and the first member of the odd series—silicon.

In considering the chemical analogies of the tin elements, the position of the members of the family in their respective series should be looked to (v. table in vol. iii. p. 811). Ge comes in series 5; it is preceded by Ga, Zn, and Cu, and succeeded by As, Se, and Br: tin comes in series 7; it is preceded by In, Cd, and Ag, and succeeded by Sb, Te, and I: lead comes in series 11; it is preceded by Tl, Hg, and Au, and succeeded by Bi and two unknown elements. The highest salt-forming oxides of the elements preceding and succeeding the tin elements in the series are: series 5, CuO , ZnO , Ga_2O_3 ; GeO_2 ; As_2O_5 , SeO_3 , —; series 5, Ag_2O , CdO , In_2O_3 ; SnO_2 ; Sb_2O_5 , TeO_2 , ? LO_2 , — series 11, Au_2O , HgO , Ti_2O_3 ; PbO ; Bi_2O_3 , —. The preceding oxides GeO_2 are, on the whole, more basic than the oxides preceding SnO_2 or PbO ; and the oxides succeeding GeO_2 are on the whole more acidic than the oxides succeeding SnO_2 or PbO . Hence we should expect the three oxides, GeO_2 , SnO_2 , and PbO_2 , to be about equally acidic and equally basic; SnO_2 , perhaps, being the most acidic of the three. Looking at the position of the tin elements in the general periodic system, we may express the relationship of these

Vol. IV.

odd-series elements to the first member of the odd series of their group (Si) by the following statements: (1) $\text{Pb:Si} = \text{Ti:Al} = \text{Hg:Mg} = \text{Au:Na} = \text{Bi:P}$. — (2) $\text{Sn:Si} = \text{In:Al} = \text{Cd:Mg} = \text{Ag:Na} = \text{Sb:P}$. — (3) $\text{Ge:Si} = \text{Ga:Al} = \text{Zn:Mg} = \text{Cu:Na} = \text{As:P}$. On the whole, Bi is more unlike P than Tl is unlike Al, Hg is unlike Mg, or Au is unlike Na; Sb is more unlike P than In is unlike Al, Cd is unlike Mg, or Ag is unlike Na; and As is more unlike P than Ga is unlike Al, Zn is unlike Mg, or Cu is unlike Na. Hence the differences between Pb and Si, tin and Si, and Ge and Si, respectively, will be very decided. If the relations expressed in the preceding statements are worked out in detail, they show that the differences between Pb and Si will be more marked than those between tin and Si, and still more marked than those between Ge and Si; but at the same time there will not be any very great differences between these three pairs of differences. Lead, then, will on the whole be the most metallic, and Ge the least metallic, of the tin elements. But the three elements will resemble each other closely in so far as their general positive or negative character is concerned. Then, considering the resemblances and differences between consecutive pairs of elements in (1) series 3 and 5 (i.e. Si and Ge series), and (2) series 5 and 7 (i.e. Ge and tin series), and (3) series 7 and 11 (i.e. tin and lead series), it is evident that Ge and Si will be more alike than Ge and tin, and that Ge and tin will more closely resemble one another than tin and lead. Hence, on the whole, we may expect that Ge will form several compounds wherein the element acts distinctly as a non-metal; it is possible that GeH_4 may be isolated (GeHCl_3 exists). Ge will form volatilisable organic compounds; GeO_2 will probably be found to be di- or trimorphous.

TITANIUM. At. w. 47.9. Mol. w. not known. Has not been fused. S.G. ρ 3.5888 (K. Hofmann, B. 26, 1025); some older determinations gave S.G. c. 5.3 (v. Fritz, M. 1892. 772; Wilson, Pr. 32, 457 [1881]). S.H. 0° to 100° $\cdot 1135$, 0° to 211° $\cdot 1288$, 0° to 301° $\cdot 1485$, 0° to 440° $\cdot 182$ (Nilson a. Pettersson, Z. P. C. 1, 84); Fritz (M. 1892. 772) gives $\cdot 13$. S.V.S. 13.4.

Historical.—In 1791 Gregor found indications of a new element in a Cornish ironsand called *menaccanite*, from the village near which it was found (Croll's Ann. 1791 [1] 40, 108). The element was called *menachin* by Kirwan. In 1795 Klaproth found a compound of a new element in a mineral known as 'rother Schoerl su Boinik in Hungarn,' and called the element *titanium* (derived from *Titan*). In 1797 K. recognised that the chief constituent of the Hungarian mineral was the same as the characteristic constituent of *menaccanite* examined by

Gregor (K., *Beiträge zur Kenntniss der Mineral-Körper*). The element was isolated for the first time by Berzelius in 1824 (P. 4, 8).

Occurrence.—Ti never occurs native. The chief ore of Ti is more or less pure TiO_2 , which occurs in different crystalline forms as *rutile* and *anatase* (tetragonal) and *brookite* (rhombic). Various minerals contain TiO_2 , combined with SiO_2 and alkaline earths, e.g. *titanite* or *sphene* and *ferrotitanite*; compounds of titanates and niobates are found in some rare minerals, e.g. *polycrase*, *euxenite*, and *pyrochlore*. Varying quantities of TiO_2 occur in many *titaniferous iron ores*. The ores of Ti are found in small quantities. Some of them, especially the titaniferous iron ores, are widely distributed (for analyses of Ti ores v. H. Rose, P. 3, 163; 14, 501; 15, 276; Mosander, P. 19, 211; Hermann, J. 25, 368; Berzelius, J. pr. 43, 50; Rammelsberg, P. 1858, 507; Scheerer, P. 64, 489; Groth, *Tabellarische Uebersicht der Mineralien* [2nd ed.] 85; O. v. d. Pfordten, B. 22, 1485). Mazade (C. R. 34, 952) found traces of Ti compounds in the mineral spring of Negrac in France. For analyses and descriptions of *anatase*, *brookite*, and *rutile* v. Klein (J. M. 1875, 337); G. vom Rath (*ibid.* 1876, 64); Schrauf (*ibid.* 1877, 403); Koch (*ibid.* 1878, 652). Cornu (C. R. 86, 101, 983) obtained spectroscopic indications of the occurrence of Ti in the sun's atmosphere. The bright-reddish crystals that are often found in blast furnaces wherein titaniferous iron ore has been smelted were supposed for many years to be Ti; but Wöhler (A. 73, 34) showed that they contain C and N besides Ti (v. TITANIUM CARBONITRIDE, p. 739).

Formation.—1. By heating K_2TiF_6 with K or Na, out of contact with air (v. *Preparation*).—2. By heating TiCl_4 with Na in a closed iron crucible heated in a wind furnace (Nilson a. Pettersson, W. 4, 554; cf. Kern, C. N. 33, 57). According to Robinson a. Hutchings (Am. 6, 74), Ti is formed by heating TiCl_4 with Na to 130° in a sealed tube; but O. v. d. Pfordten (A. 237, 201) says that very little, if any, Ti is obtained, and that the main product is TiCl_3 .—3. By fusing K_2TiF_6 with an equal weight of iron filings, and dissolving away the iron by HClAq (Wehrlin a. Giraud, C. R. 85, 288).—4. By heating TiCl_4 to 180° with Ag obtained by reducing a salt of Ag; Ti_2Cl_6 is also formed (Friedel a. Guérin, A. Ch. [5] 7, 24).

Preparation.—Finely-powdered *rutile* is mixed with double its weight of K_2CO_3 , and the mixture is fused in a Pt crucible placed inside an earthenware crucible. The fused mass is powdered and dissolved in the necessary quantity of HFAq in a Pt dish; water is added to dissolve K_2TiF_6 , which begins to separate, the liquid is boiled and filtered while boiling; the K_2TiF_6 , which separates from the filtrate in lustrous crystalline crusts, is pressed between filter-paper, washed repeatedly with cold water, again pressed, and recrystallised several times from boiling water (Wöhler, A. 74, 212). The dry K_2TiF_6 is placed in a porcelain boat in a porcelain (or hard glass) tube connected with a supply of pure dry H; another boat, containing Na, is also placed in the tube; H is passed through the apparatus, and the Na is gradually vaporised and driven over the K_2TiF_6 , which is heated.

When the action is completed and the tube has cooled (the H stream being maintained), the solid is treated with water, which dissolves out KF , NaF , and Na (W. a. Deville, A. 103, 280). The Ti is finally washed with ether and dried over H_2SO_4 (v. Kern, C. N. 33, 57). Merz (P. 73, 48) prepared Ti by heating a mixture of six pts. K_2TiF_6 and three pts. NaCl with two pts. Na in a glass bulb placed in a sand-bath, while a stream of H was passed through the bulb, then adding zinc-powder and fusing, and dissolving out the zinc by cold dilute HClAq .

Properties.—A dark-grey or black lustrous powder; has not been obtained crystallised. Ti resembles iron reduced from Fe_2O_3 by H at a low temperature.

According to Junot (J. 1853, 386), Ti was obtained by him as a silver-white lustrous deposit by electrolysing a solution prepared by dissolving titanate of K in boiling $\text{H}_2\text{SO}_4\text{Aq}$, evaporating to a syrup, and extracting with $\text{Na}_2\text{SO}_4\text{Aq}$. J.'s experiments do not seem to have been repeated. Lévy (C. R. 110, 1368) obtained hard, steel-white, cubicle crystals, which he took to be nearly pure Ti, by passing TiCl_4 vapour over Si, B, or several metals heated to bright redness. L. found only 80 p.c. Ti in the crystals. Ti burns brilliantly in a flame. When heated to redness in O, it is oxidised with production of an intensely brilliant white light. Ti also burns in Cl. It decomposes water at 100° . Warm HClAq dissolves Ti easily; it is also at once dissolved by HFAq . Heated by electric sparks, Ti gives an emission-spectrum very rich in lines (v. Thalen, A. Ch. [4] 18, 239; Troost a. Hautefeuille, C. R. 73, 620; Cornu, C. R. 86, 101, 983; Liveing a. Dewar, Pr. 32, 402).

The atomic weight of Ti has been determined (1) by analyses of TiCl_4 (H. Rose, P. 15, 145 [1829]; Pierre, A. Ch. [3] 20, 257 [1847]; Thorpe, C. J. 47, 108 [1885]); (2) by determining the weight of TiO_2 got from a determinate weight of TiCl_4 (H. Rose, *l.c.*; Thorpe, *l.c.*); (3) by analyses of TiBr_4 (Thorpe, *l.c.*); (4) by determining the weight of TiO_2 got from a determinate weight of TiBr_4 (Thorpe, *l.c.*); (5) by measuring S.H. of Ti (Nilson a. Pettersson, Z. P. C. 1, 34); (6) by determining V.D. of TiCl_4 and TiI_4 (v. these compounds). Rose's determinations gave values for the at. w. of Ti varying from 47.92 to 48.32; Pierre's values varied from 50.2 to 50.29. The very accurate series of determinations made by Thorpe has settled the at. w. to be almost exactly 48 (48.01 if O=16; 47.9 if O=15.96).

The atom of Ti is tetravalent in the gaseous molecules TiCl_4 and TiI_4 . Ti is metallic in many of its chemical properties; it decomposes water, giving off H; the oxides Ti_2O_3 and TiO , form corresponding salts; the chloride and iodide (and ? also bromide) can be gasified without decomposition; the sulphide TiS_2 does not show any acidic characters so far as it has been examined. The chlorides give pps. of corresponding hydrated oxides by reacting with alkalis, &c. On the other hand, Ti exhibits distinctly non-metallic or chlorous properties; hydrates of TiO act as feeble acids, producing salts wherein Ti forms part of the negative radicle. The acids H_2TiF_6 and H_2TiO_6 are known, and also salts derived therefrom. TiCl_4 is very easily decomposed by

water, giving HClAq and $\text{TiO}_2 \cdot x\text{H}_2\text{O}$, &c. As might be expected from the two-sided character of the reactions of Ti, most of the salts obtained by replacing the H of oxyacids by Ti are basic salts. The oxide TiO_2 has been isolated; it is probably a superoxide. Ti is closely related to Zr, Ce, and Th; these elements, with Ti, form the even-series family of Group IV. (v. TITANIUM GROUP OF ELEMENTS, p. 749). Ti is also closely related to Ge, Sn, and Pb, which form the odd-series elements of Group IV. (v. TIN GROUP OF ELEMENTS, p. 785). Ti also shows distinct relationships to C and Si, which are the first and second members of Group IV. (v. CARBON GROUP OF ELEMENTS, vol. i. p. 682). The similarity between Ti and Si is shown very distinctly in the titanio and silicio acids, the relations between which may be expressed by such a general equation as $n\text{MH}_2\text{O}_2 - m\text{H}_2\text{O} = \text{M}_n\text{H}_{4n-2m}\text{O}_{4n-m}$ ($\text{M} = \text{Ti}$ or Si). Ti is the only element of Group IV, which is known to form compounds of the type $\text{M}_2\text{TiO}_4\text{F}_4 = \text{Ti}(\text{OM})_2\text{F}_4 = \text{TiX}_4$.

Reactions and Combinations.—1. Heated in air or in oxygen, burns brilliantly to TiO_2 .—2. Burns when heated in chlorine, forming Ti_2Cl_4 .—3. TiI_4 is formed by passing vapour of iodine over hot Ti.—4. Combines with nitrogen when heated therewith (v. *Nitrides*, p. 743).—5. Ti is violently oxidised to TiO_2 by heating with cupric oxide or red lead.—6. Interacts with water at 100° , forming TiO_2 and H.—7. Dissolves in warm hydrochloric acid, forming Ti_2Cl_4 (Glatzel, B. 9, 1831; Rammelsberg, B. B. 1874. 490).—8. Ti dissolves easily in hydrofluoric acid (? forming Ti_2F_4); also in warm dilute nitric or sulphuric acid, according to Glatzel (l.c.), the solution in $\text{H}_2\text{SO}_4\text{aq}$ deposits crystals of $\text{Ti}_2(\text{SO}_4)_2$ on cooling. Conc. hot H_2SO_4 reacts with Ti, giving off SO_2 (? forming $\text{Ti}(\text{SO}_4)_2$); conc. hot HNO_3 oxidises Ti to metatitanic acid (q. v., p. 747) according to Weber (P. 120, 287).

Detection and Estimation.—Compounds of Ti are not reduced to metal by heating on charcoal in the blowpipe flame. Ti compounds, if not containing elements which give a colour to microcosmic salt, form a colourless glass when melted in the microcosmic salt bead in the outer blowpipe flame; in the inner flame they give a glass which is colourless when hot, but becomes violet on cooling; the delicacy of the reaction is much increased by adding a little zinc to the bead (Riley, C. J. 12, 18). Solutions of $\text{TiO}_2 \cdot x\text{H}_2\text{O}$ in HClAq or $\text{H}_2\text{SO}_4\text{aq}$ give white pps. of $\text{TiO}_2 \cdot x\text{H}_2\text{O}$ on boiling; addition of a piece of tin to a solution of $\text{TiO}_2 \cdot x\text{H}_2\text{O}$ in HClAq causes evolution of H and produces a violet-blue solution which becomes rose-coloured on dilution with water (von Kobell, P. 62, 599). A solution of $\text{TiO}_2 \cdot x\text{H}_2\text{O}$ in HClAq gives a violet-red liquid (Ti_2Cl_4 solution) by digestion for some time with Cu (Fuchs, A. 56, 319). Ti is estimated as TiO_2 , ppd. from solutions by a slight excess of NH_4Aq . Insoluble compounds of Ti are generally fused with KHSO_4 , the fused mass is dissolved in water, and $\text{TiO}_2 \cdot x\text{H}_2\text{O}$ is ppd. by long continued boiling.

Titanium, alloys of. The alloys of Ti have not been much examined. Wöhler & Michel (A. 118, 248; 115, 102) obtained an alloy with aluminium approaching in composition to TiAl_2 , by heating a mixture of TiO_2 , KCl, NaCl, and

cryolite, and treating with HClAq . By heating a mixture of Ti and Al with KCl or NaCl in an earthenware crucible in a stream of H, Lévy (C. R. 106, 66) obtained brittle steel-grey crystals which he took to be an isomorphous mixture of TiAl and SiAl . Ti alloys with iron; it is often present in pig-iron, but rarely in bar-iron or steel (v. Riley, C. J. 16, 387).

Titanium, bromides of. Only one bromide has been isolated, TiBr_4 .

TITANIO BROMIDE TiBr_4 . (*Titanium tetrabromide*.) Mol. w. has not been determined, but the formula is almost certainly molecular from analogy of TiCl_4 and TiI_4 .

Prepared by passing Br vapour over a mixture of TiO_2 and charcoal heated to full redness, collecting the liquid that distils over and solidifies in the receiver, and redistilling it from Hg (to remove free Br) (Duppa, Pr. 8, 42). Also prepared by passing HBr gas over TiCl_4 kept a few degrees below its boiling-point in a distilling flask connected with an upright condenser; the whole of the Cl of the TiCl_4 is expelled (Thorpe, C. J. 47, 126). Thorpe used 350 g. TiCl_4 , and continued the passage of HBr for three days. The HBr is conveniently obtained by the interaction of Br and amorphous P in a little water; it is freed from Br by passing through a U tube containing broken glass and amorphous P, and is dried by passing through another U tube containing CaCl_2 .

TiBr_4 forms dark-yellow or orange crystals, S.G. 2.6, melting at c. 40° , and boiling at c. 229° (D., l.c.; T., l.c.). It is very hygroscopic; easily decomposed by water, forming a perfectly clear solution containing HBr and $\text{TiO}_2 \cdot x\text{H}_2\text{O}$.

Titanium, bromochlorides of. By adding Br to TiCl_4 (q. v., p. 741) Friedel & Guérin (A. Ch. [5] 8, 24) obtained a colourless liquid, fuming in the air, boiling at 176° , which they said was probably TiBr_2Cl_2 ; and by the reaction of Br with Ti_2Cl_4 they obtained a liquid boiling at 154° , probably TiBrCl_3 .

Titanium, carbonitride of, Ti_2CN_4 . (*Titanium nitrocyanide*, or *cyanonitride* $\text{Ti}_2(\text{CN})_2\text{N}_2$.) This compound is often found in blast furnaces where in titaniferous ironstone has been smelted. It was supposed by Wollaston to be Ti (G. A. 75, 220), and was for many years generally mistaken for the metal. In 1850 Wöhler (A. 73, 84) proved it to contain C and N besides Ti.

The compound is found in blast furnaces as lustrous, opaque, copper-coloured, prismatic crystals. By treating these crystals with conc. HClAq , then with conc. H_2SO_4 , washing, treating with HFAq , and again washing, the compound is freed from admixed Fe, &c.; small leaflets of graphite generally remain mixed with the carbonitride. Ti_2CN_4 can be prepared by heating a mixture of dry K_2FeCy , and TiO_2 in a closed crucible for an hour or two at c. the melting-point of Ni (1400° to 1450°), dissolving out Fe, &c., by conc. HClAq , washing, and drying. By examining the brown powder thus obtained with a magnifying power of 800 diameters copper-coloured crystals of Ti_2CN_4 can be detected (Wöhler, A. 73, 84). It is also obtained by heating a mixture 1 part C and $\frac{5}{2}$ parts TiO_2 in a closed carbon crucible for some hours at 1400° to 1450° ; also by passing N over a mixture of C and TiO_2 in the ratio 1: $\frac{5}{2}$ heated in a carbon

boat placed in a carbon tube to the melting-point of Pt (c. 1800°) (W. a. Deville, *A.* 103, 231).

When Ti_2CN_4 is fused with KOH it gives off NH_3 ; heated to redness in a stream of water vapour TiO_2 is formed, and H, NH_3 , and HCN are given off (W., *l.c.*); heated in Cl it gives $TiCl_4$ and $TiCl_3 \cdot 2HCN$ (W., *l.c.*; also p. 219); the compound is burnt by heating with PbO, CuO, or HgO, giving off CO_2 and leaving TiO_2 , and Pb, Cu, or Hg (much heat is produced in the reaction) (W., *l.c.*).

The simplest formula that expresses the composition of Ti carbonitride is Ti_2CN_4 (W., *l.c.*; cf. Reinhardt, *Zeit. für anorgan. Chemie*, 1, 124). This formula is generally doubled and written $Ti(CN)_2 \cdot 3Ti_2N_4$, and the substance is regarded as a compound of cyanide and nitride of Ti; Joly (*C. R.* 82, 1195) regards it as a compound of carbide and nitride of Ti, and writes the formula Ti_2O_4TiN (or $2Ti_2O_4TiN$).

Titanium, chlorides of. Ti and Cl combine to form $TiCl_4$; by the regulated action of H on $TiCl_4$ one-fourth of the Cl can be removed and $TiCl_3$ produced; and by the further action of H on $TiCl_3$ one-third of the Cl can be removed and $TiCl_2$ produced. The V.D. of the tetrachloride has been determined, and the formula $TiCl_4$ is molecular; from the analogy of C_2Cl_6 and Si_2Cl_6 it is probable that the molecular formula of the trichloride is Ti_2Cl_6 ; from the analogy of $PbCl_2$ and $SnCl_2$ the formula $TiCl_2$ may be supposed to be molecular, but if the analogy of C_2Cl_4 is to be followed, the molecular formula must be Ti_2Cl_4 .

TITANIC CHLORIDE $TiCl_4$. (*Titanium tetrachloride*.) Mol. w. 189.38. Melts at -25° (Haase, *B.* 26, 1052). Boils at 136.41° at 760 mm. (Thorpe, *C. J.* 87, 329). S.G. $_{25}^{20}$ 1.76041; S.G. at b.p. 1.52223 (Thorpe, *l.c.*). V.D. 98.8 at 143° (Dumas, *A. Ch.* [2] 83, 388). S.V. 124.47 (Thorpe, *l.c.*).

Preparation.—1. TiO_2 is intimately mixed with c. half its weight of lampblack previously heated to redness in a stream of Cl, and the mixture is heated to full redness in a tube of hard glass connected with a receiver, while a stream of dry Cl is passed over it. The $TiCl_4$ which collects in the receiver is freed from Cl by shaking with Cu, Hg, or Na amalgam (Merz, *Bl.* [2] 7, 401), or by boiling for some time (Thorpe, *C. J.* 47, 119), and is then distilled. Thorpe (*l.c.*) conducted the final distillation in dry N.—2. Vapour of $COCl_2$, or a mixture of equal volumes of Cl and CO , is passed over TiO_2 in small lumps, heated to bright redness in a tube of hard glass connected with a receiver. The $TiCl_4$ is purified as described above (Watts a. Bell, *C. J.* 83, 443).

Properties.—A colourless liquid, solidifying at -25° (Haase, *B.* 26, 1052). Does not conduct electricity (O. v. d. Pfordten, *A.* 237, 201). Fumes in the air, rapidly absorbing moisture and solidifying to the hydrate $TiCl_4 \cdot 5H_2O$ (Demoly, *A.* 72, 213). (For an apparatus for collecting $TiCl_4$ for analysis, v. Thorpe, *l.c.*) $TiCl_4$ is violently decomposed by water, forming $HClAq$, and $TiO_2 \cdot xH_2O$ some of which ppts. (v. *Reactions*, No. 8).

Reactions.—1. *Hydrogen* reduces $TiCl_4$, at a high temperature, to Ti_2Cl_3 , and then to $TiCl_3$ (v. *trichloride* and *dichloride*).—2. Mixed with *oxygen* and passed through a red-hot porcelain

tube, $Ti_2O_3Cl_2$ is formed (v. *Oxychlorides*, p. 748). 3. Heated to 180° in a sealed tube with *sodium*, the chief product is $TiCl_4$, according to O. v. d. Pfordten (*A.* 237, 201); Robinson a. Hutchings (*Am.* 6, 74) say that Ti is produced in this reaction. Nilson a. Pettersson (*W.* 4, 554) obtained Ti by reducing $TiCl_4$ by Na at a very high temperature.—4. *Sodium-amalgam* produces Ti_2Cl_4 and $TiCl_3$ (O. v. d. P., *l.c.*).—5. Reduced *silver* gives Ti_2Cl_4 , and Ti when heated with $TiCl_4$ to 180° (Friedel a. Guérin, *A. Ch.* [5] 7, 24).—6. By passing vapour of $TiCl_4$ over *silicon*, *boron*, or several *metals*, heated to bright redness, Lévy (*C. R.* 110, 1368) obtained hard, steel-white, cubical crystals which he supposed to be nearly pure Ti.—7. Pure, dry, *hydrogen sulphide* reacts at the ordinary temperature, forming Ti_2Cl_6 ; at a higher temperature a pp. is produced which is probably a thiochloride of Ti (O. v. d. P., *A.* 234, 257).—8. Cold *water* reacts violently with $TiCl_4$, with production of much heat and formation of a turbid liquid containing HCl and holding in suspension $2Ti_2O_3 \cdot H_2O$ (v. *Metatitanic acid* under **TITANIUM OXYACIDS, AND SALTS AND DERIVATIVES THEREOF**, p. 747); after 30 or 40 hours the liquid becomes clear, but ppn. occurs again on heating to c. 85° when about 7 pts. water are present to 1 pt. $TiCl_4$ used (v. Thorpe, *C. J.* 47, 120; and cf. **TITANIUM OXYACIDS**, p. 746). According to Merz (*Bl.* [2] 7, 401), an oxychloride, approximately $TiCl_3 \cdot 3Ti_2O_3 \cdot 16H_2O$, is obtained by evaporating $TiCl_4Aq$, or $TiCl_4$ that has deliquesced in air, over H_2SO_4 and CaO (v. *Oxychlorides*, p. 748). TiO_2 , in the form of *brookite*, is obtained by passing vapour of $TiCl_4$ and *water*, mixed with CO_2 , through a red-hot porcelain tube (Daubrée, *C. R.* 29, 227; 39, 153).—9. With *hydrochloric acid* the compounds $TiCl_3 \cdot OH$ and $TiCl_2 \cdot (OH)_2$ are formed (v. **TITANIUM HYDROXYL CHLORIDES**, p. 743).—10. *Chlorosulphonic acid* ($SO_3 \cdot OH \cdot Cl$) reacts with $TiCl_4$ at the ordinary temperature to form a yellow, amorphous, deliquescent powder, having the composition $TiCl_4 \cdot SO_3$ ($= TiCl_4 \cdot OSO_3 \cdot Cl$) (Clausnizer, *B.* 11, 2011).—11. By passing vapour of $TiCl_4$, mixed with H, through a white-hot tube containing *titanium dioxide* the oxychloride $Ti_2O_3Cl_2$ is obtained (v. *Oxychlorides*, p. 748).

Combinations.—1. With *water* to form a pentahydrate and a dihydrate. Demoly (*A.* 72, 213) obtained $TiCl_4 \cdot 5H_2O$, as deliquescent crystals, by allowing $TiCl_4$ to absorb moisture from the air, then adding a little more water, and evaporating under reduced pressure. By drying the pentahydrate over H_2SO_4 in *vacuo*, D. obtained $TiCl_4 \cdot 2H_2O$.—2. With *ammonia*, to form $TiCl_4 \cdot 4NH_3$, according to H. Rose (*P.* 16, 57), $TiCl_4 \cdot 6NH_3$, according to Persoz (*A. Ch.* [2] 46, 315); easily decomposed in air; heated in a tube gives off NH_3 , then NH_4 and HCl, and a yellowish sublimate of $TiCl_3 \cdot 3NH_4 \cdot Cl$ and leaves Ti; heated in NH_3 gives Ti_2N_4 (v. **TITANIUM NITRIDES**, p. 743). 3. With *hydrogen phosphide*, to form a brown powder, which when heated gives a sublimate of $3TiCl_4 \cdot 2PH_3 \cdot Cl$ according to H. Rose (*P.* 43, 527). 4. With *hydrogen cyanide* to form $TiCl_4 \cdot 2HCN$ (Wöhler, *A.* 73, 226); by vapourising this compound through a red-hot tube Ti_2N_4 and C are formed (W., *l.c.*).—5. With *cyanogen chloride*, to form yellow crystals of $TiCl_4 \cdot ONCl$; sublimable at 100° (W., *A.* 73, 219).—6. With *phosphorus*

pentachloride to form $\text{TiCl}_4 \cdot \text{PCl}_5$; obtained by heating TiCl_4 and PCl_5 to 150° in a sealed tube (Bertrand, *Bl.* [2] 33, 565); also by heating TiO_2 and PCl_5 in the ratio $\text{TiO}_2 : 3\text{PCl}_5$, or by saturating a mixture of TiCl_4 and PCl_5 with Cl (Tütschhoff, *A.* 141, 111), and removing excess of TiCl_4 by heating in a stream of Cl (Weber, *P.* 132, 452). A citron-yellow, loose, semi-crystalline solid; sublimes without melting; deliquescent in air.—7. With **phosphorus trichloride** to form yellow crystals of $\text{TiCl}_4 \cdot \text{PCl}_3$, melting at 85.5° (Bertrand, *l.c.*).—8. With **sulphur tetrachloride**, to form $2\text{TiCl}_4 \cdot \text{SCl}_4$; obtained by saturating a mixture of TiCl_4 and S_2Cl_2 with Cl , and warming in a stream of Cl (Weber, *P.* 132, 454).—9. By mixing TiCl_4 and **sulphurous chloride** H. Rose obtained large yellow crystals, probably a compound of the two chlorides (*P.* 42, 527).—10. With **ammonium chloride**, to form $\text{TiCl}_4 \cdot 3\text{NH}_4\text{Cl}$ (*v. supra*, *Combinations*, No. 2).—11. With **phosphoryl chloride** to form $\text{TiCl}_4 \cdot \text{POCl}_3$; obtained by gradually adding POCl_3 to TiCl_4 , and gently warming (Weber, *P.* 132, 453); colourless, deliquescent crystals, melting at 110° , and boiling at 140° (Wehrlin & Giraud, *C. R.* 85, 288).—12. With **selenium oxychloride** to form a yellow powder, decomposed by heat, having the composition $\text{TiCl}_4 \cdot 2\text{SeOCl}_2$; obtained by adding SeOCl_2 to TiCl_4 , and drying the solid that separates on cooling on a tile over H_2SO_4 (Weber, *B.* 1865, 154).—13. With **nitrosyl chloride**; obtained by saturating TiCl_4 with NO_2 , and subliming (Hampe, *A.* 126, 47), also by passing the vapours from *aqua regia* into TiCl_4 (Weber, *P.* 118, 476). Hampe (*l.c.*) gives the composition $3\text{TiCl}_4 \cdot 4\text{NOCl}$, Weber (*l.c.*) the composition $\text{TiCl}_4 \cdot 2\text{NOCl}$. A deep citron-yellow, crystalline mass; decomposes in air; sublimable out of air; with water gives off NO .—14. With **sulphur trioxide** to form $\text{TiCl}_4 \cdot \text{SO}_3$ (or $\text{TiCl}_4 \cdot \text{OSO}_2\text{Cl}$), formed by the interaction of TiCl_4 and $\text{SO}_2 \cdot \text{OH} \cdot \text{Cl}$ at the ordinary temperature; a yellow, amorphous, deliquescent powder (Clausnizer, *B.* 11, 2011).—15. Demarcay (*Bl.* [2] 20, 127) obtained a great many compounds of TiCl_4 with **esters, mercaptans, and ethyl sulphide** (*cf.* Bedson, *C. J.* 29, 309).

TITANIUM TRICHLORIDE TiCl_3 . (*Titanium sesquichloride*. *Titanous chloride*.) Mol. w. not determined; but from analogy of C_2Cl_6 and Si_2Cl_6 , the formula Ti_2Cl_6 is probably molecular.

Formation.—1. By reducing TiCl_4 by H (*v. Preparation*).—2. By reducing TiCl_4 by sodium-amalgam (O. v. d. Pfordten, *A.* 237, 201); or by pure, dry H_2S (O. v. d. P., *A.* 234, 257).—3. By heating TiCl_4 with reduced Ag to 180° ; Ti is also formed, and probably TiCl_2 also (Friedel & Guérin, *A. Ch.* [5] 8, 24).—4. A solution of Ti_2Cl_6 is obtained by digesting a solution of $\text{TiO}_2 \cdot x\text{H}_2\text{O}$ in HClAq with Cu at 40° – 50° (Fuchs, *A.* 56, 319); or with Ag ppd. by zinc from AgCl (von Kobell, *P.* 62, 599). Ti_2Cl_6 is also probably present in the greenish liquid obtained by adding Na amalgam to K_2TiF_6 in HClAq (O. v. d. P., *A.* 237, 201).

Preparation.— TiCl_3 is placed in a retort connected with a tube of porcelain or hard glass (if a glass tube is used it should be wrapped in copper-foil) which is placed horizontally in a furnace; the other end of the tube projects considerably out of the furnace and is connected with a receiver to collect un Decomposed TiCl_3 .

The delivery tube from an apparatus evolving pure and dry H passes into the retort beneath the surface of the TiCl_3 . H is passed through the apparatus until it is entirely filled with the gas; the tube is then heated to redness, and the retort is gently warmed. Ti_2Cl_6 is formed and condenses as dark-violet scales on the part of the tube that projects out of the furnace. When all the TiCl_3 has been driven out of the retort, the Ti_2Cl_6 in the cooler part of the tube is gently warmed, while the passage of H is continued, to remove any adhering TiCl_3 ; the Ti_2Cl_6 is allowed to cool in the stream of H (Ebelmen, *A. Ch.* [3] 20, 385).

Properties.—A dark-violet, very lustrous solid, deliquescent in air, and dissolving in water to form a violet liquid, which gradually decolorises with ppn. of $\text{TiO}_2 \cdot x\text{H}_2\text{O}$. Ti_2Cl_6 is easily soluble in alcohol, forming a violet or green liquid; it is insoluble in ether, and sparingly soluble in HClAq (O. v. d. P., *A.* 237, 201).

Reactions.—1. Heated in *hydrogen* to c. 440° , TiCl_3 distils over and TiCl_2 remains (Friedel & Guérin, *A. Ch.* [5] 8, 24).—2. Heated in *air*, TiCl_3 vaporises and TiO_2 remains.—3. Dissolves in *water*, forming a violet, or green-violet, liquid which slowly becomes colourless with ppn. of $\text{TiO}_2 \cdot x\text{H}_2\text{O}$.—4. *Alkalis*, or *alkali carbonates*, in solution ppt. $\text{Ti}_2\text{O}_3 \cdot x\text{H}_2\text{O}$ from $\text{Ti}_2\text{Cl}_6\text{Aq}$; *ammonium sulphide* forms the same pp.; *hydrogen sulphide* gives no pp. (Ebelmen, *l.c.*).—5. $\text{Ti}_2\text{Cl}_6\text{Aq}$ reduces *solutions of gold, silver, or platinum salts* with ppn. of the metals; *ferric and cupric salts* are reduced to ferrous and cuprous salts; *sulphurous acid solution* is reduced by heating with $\text{Ti}_2\text{Cl}_6\text{Aq}$ with ppn. of S (E., *l.c.*).—6. Ti_2Cl_6 reacts with *bromine* to form a liquid boiling at 154° , probably TiBrCl_3 (F. a. G., *l.c.*).

Combinations.—With *water* to form $\text{Ti}_2\text{Cl}_6 \cdot 8\text{H}_2\text{O}$; obtained by Glatzel (*B.* 9, 1829) by evaporating a solution of Ti in HClAq to the crystallising point, filtering off ppd. $\text{TiO}_2 \cdot x\text{H}_2\text{O}$ from time to time. The hydrate is a green solid; it dissolves in *water*, forming an opalescent violet solution containing a little suspended $\text{TiO}_2 \cdot x\text{H}_2\text{O}$; the solution becomes colourless on standing, and then gives the reactions of titanous acid.

TITANIUM DICHLORIDE TiCl_2 . (Sometimes called *titanous chloride*.) Mol. w. is not known. From the analogy of SnCl_2 and PbCl_2 , the formula TiCl_2 would be molecular; but from the analogy of C_2Cl_6 , the molecular formula would be Ti_2Cl_4 .

Formation.—1. By reducing Ti_2Cl_6 by H (*v. Preparation*).—2. TiCl_2 is probably formed, along with Ti_2Cl_6 , by heating TiCl_4 with reduced Ag (Friedel & Guérin, *A. Ch.* [5] 8, 24).—3. Along with Ti_2Cl_6 , by the action of Na amalgam on TiCl_4 ; also by heating TiCl_4 with Na to 180° in a sealed tube (O. v. d. Pfordten, *A.* 237, 201).

Preparation.— Ti_2Cl_6 reacts with H at a red heat to give TiCl_2 and TiCl_3 . Friedel & Guérin (*l.c.*) proceed as follows. The tube containing Ti_2Cl_6 , prepared from TiCl_4 (*v. supra*), while still filled with H , is connected with an apparatus evolving pure, dry CO_2 , and the whole of the H in the apparatus is driven out by CO_2 . The Ti_2Cl_6 is then shaken into a small tubulated retort, placed on a sand-tray, and previously filled with CO_2 ; the CO_2 is displaced by pure, dry H ; the retort is then heated to dull red-

ness, while a stream of H is passed through it, until TiCl_4 ceases to distil off; the retort is allowed to cool in the stream of H, and CO_2 is then passed in until all the H is removed (if this is omitted the TiCl_4 takes fire in the air), and the black TiCl_4 in the retort is quickly shaken into small dry tubes filled with CO_2 , which are at once sealed off.

Properties.—A black, light powder; very rapidly absorbs water, forming a kind of mud; insoluble in CS_2 , CHCl_3 , or Et_2O . Volatilised without melting by heating to full redness in H. Shaken with Et_2O and KONSAq , the Et_2O becomes dark brown; this is a delicate test for TiCl_4 (O. v. d. Pfordten, A. 237, 201).

Reactions.—1. Takes fire when touched with a drop of water (? with formation of $\text{Ti}_2\text{O}_3\text{Cl}_2$; v. F. a. G., l.c.); thrown into water, it hisses like red-hot iron, decomposing the water with evolution of H and formation of a yellowish liquid.—2. Decomposes absolute alcohol, giving off H and forming a yellowish liquid.—3. Heated in air, TiCl_4 burns like tinder, giving off TiCl_3 and leaving TiO_2 .—4. With bromine it forms a liquid boiling at 176° , probably TiCl_2Br_2 (F. a. G., l.c.).

Titanium, chlorobromides of, v. TITANIUM BROMOCHLORIDES, p. 739.

Titanium, cyanonitride of, v. TITANIUM CARBONITRIDE, p. 739.

Titanium, ferrocyanides of, v. vol. ii. p. 337.

Titanium, fluorides of. The only compound that has been isolated with certainty is TiF_4 . There are indications of the existence of Ti_2F_7 , and compounds of this fluoride with alkali fluorides are known.

TITANIC FLUORIDE TiF_4 . (*Titanium tetrafluoride*.) Formula probably molecular, from analogy of TiCl_4 and TiI_4 . By heating a mixture of TiO_2 and CaF_2 with H_2SO_4 , Unverdorfen (P. 7, 820) obtained a colourless distillate, which he supposed to contain a compound of Ti and F. Berzelius (P. 4, 1) obtained crystals (? TiF_4) by dissolving $\text{TiO}_2 \cdot x\text{H}_2\text{O}$ in HFAq . The crystals were decomposed by water, giving an acid solution (? $\text{H}_2\text{TiF}_6\text{Aq}$), and an insoluble, 'so to say basic,' compound. TiO_2 is obtained by passing vapour of TiF_4 , mixed with H_2O , through a tube heated to c. 800° or 1000° (Hautefeuille, A. Ch. [4] 4, 181; cf. TITANIUM DIOXIDE, p. 741). Heated to redness in H, perhaps gives Ti_2F_6 (H., l.c.).

Combinations.—1. TiF_4 probably combines with hydrogen fluoride to form H_2TiF_6 . By dissolving $\text{TiO}_2 \cdot x\text{H}_2\text{O}$ in HFAq , evaporating, adding water to the crystals (? TiF_4) thus formed, and filtering from an insoluble solid (? oxyfluoride), Berzelius (P. 4, 1) obtained an acid solution from which, by neutralisation with KOHAc and evaporation, he obtained the salt K_2TiF_6 . The acid solution probably contained H_2TiF_6 . This compound (if it exists) is best called *titaniofluorhydric acid*. It is analogous to H_2SiF_6 , H_2SnF_6 , and other acids of the type H_2MX_6 , where M = an element of Group IV. (except C), and X = a halogen.—2. With various metallic fluorides to form $\text{TiF}_4 \cdot 2\text{MF} = \text{M}_2\text{TiF}_6$. These salts were obtained from the K salt, which was got by neutralising the acid solution prepared as described under 1. Salts of NH_4 , Ca, Cu, Fe, Pb, Mg, and Ni are described (B., l.c.; Weber,

P. 120, 291). These salts are best called *titaniofluorides*; they are similar to stanniofluorides.—3. TiF_4 also combines with ammonium fluoride to form $\text{TiF}_4 \cdot 3\text{NH}_4\text{F}$ (besides $\text{TiF}_4 \cdot 2\text{NH}_4\text{F}$) (Baker, C. J. 85, 768).

By adding NH_4Aq , drop by drop, to warm $(\text{NH}_4)_2\text{TiF}_6\text{Aq}$, Piccini (G. 17, 479) obtained a compound of the form $\text{TiO}_2 \cdot \text{F}_2 \cdot x\text{NH}_4\text{F}$; from this he prepared $\text{TiO}_2 \cdot \text{F}_2 \cdot \text{BaF}_2$, and by carefully decomposing this salt by $\text{H}_2\text{SO}_4\text{Aq}$ he obtained a solution of the acid $\text{TiO}_2 \cdot \text{F}_2 \cdot 2\text{HF}$. P. regards this acid as a F derivative of the hypothetical *pertitanic acid* H_2TiO_4 (the acid of TiO_2); he calls the acid *fluoroxypertitanic acid*, and the salts *fluoroxypertitanates*. Following the plan adopted in this Dictionary, the acid will be called *titaniooxyfluorhydric acid* $\text{H}_2\text{TiO}_2\text{F}_4$, and the salts, $\text{M}_2\text{TiO}_2\text{F}_4$, will be called *titaniooxyfluorides*. $\text{H}_2\text{TiO}_2\text{F}_4\text{Aq}$ is a yellow liquid, not pptd. by Ba salts, giving a pp. of TiO_2 with alkali carbonates.

TITANIUM TRIFLUORIDE TiF_3 . This compound is said to be formed by strongly heating K_2TiF_6 in a stream of H with a little HCl, according to Hautefeuille (C. R. 59, 189; cf. 57, 451). According to H., the compound is a purple-red solid, soluble in water. By treating $\text{Ti}_2\text{Cl}_7\text{Aq}$ with KHF_2 or NH_4F , Piccini (G. 16, 104) obtained violet pps. of $\text{Ti}_2\text{F}_7 \cdot 2\text{MF}$, where M = NH_4 or K; he also obtained $\text{Ti}_2\text{F}_7 \cdot 3\text{NH}_4\text{F}$. The K salt is slightly soluble in water; soluble in dilute acids, forming green liquids, from which alkalis throw down azure-blue pps. that gradually oxidise to $\text{TiO}_2 \cdot x\text{H}_2\text{O}$ on exposure to air. The salt $\text{TiF}_4 \cdot 3\text{NH}_4\text{F}$, when exposed to air, gradually oxidises to $\text{TiO}_2 \cdot \text{F}_2 \cdot 3\text{NH}_4\text{F}$.

Titanium, haloid compounds of. Ti combines with the halogens directly to form compounds TiX_4 ; these tetrahalides are generally prepared by passing the halogen as gas over a red-hot mixture of TiO_2 and C. TiI_4 is best prepared by heating TiCl_4 in HI gas, and TiBr_4 is very conveniently prepared by heating TiCl_4 in HBr gas; TiF_4 is prepared by dissolving $\text{TiO}_2 \cdot x\text{H}_2\text{O}$ in HFAq and evaporating. The two tetrahalides TiCl_4 and TiI_4 have been gasified. These formulæ are molecular, hence the formulæ TiF_4 and TiBr_4 probably also represent the compositions of the gaseous molecules of these compounds. By the action of H, or certain other reducing agents, on TiCl_4 , two chlorides are obtained, Ti_2Cl_7 and Ti_2Cl_9 . The V.D. of neither has been determined, but from the analogy of C_2Cl_4 and Si_2Cl_6 , the value of x in Ti_2Cl_x is probably 2; from the analogy of C_2Cl_4 , the molecular formula of the lowest chloride is probably Ti_2Cl_4 , but from the analogy of SnCl_4 and PbCl_4 the formula TiCl_4 would be given to it. Ti_2F_7 , or TiF_4 , probably exists. No bromide or iodide of either type Ti_2X_x , or Ti_3X_x , has been isolated. Two bromochlorides of the types Ti_2X_4 and Ti_3X_6 probably exist. TiCl_4 and TiBr_4 dissolve in cold water; the solutions contain HXAc and $\text{TiO}_2 \cdot x\text{H}_2\text{O}$; dilution, and more quickly heating, ppts. insoluble $\text{TiO}_2 \cdot x\text{H}_2\text{O}$ from the solution of TiCl_4 . TiF_4 is decomposed by water, giving $\text{H}_2\text{TiF}_6\text{Aq}$ (and ? an oxyfluoride). TiI_4 is also decomposed by water; on heating insoluble $\text{TiO}_2 \cdot x\text{H}_2\text{O}$ separates. TiCl_4 combines with many non-metallic chlorides and oxychlorides. TiF_4 combines with metallic fluorides,

forming salts M_2TiF_6 , and also some more complex salts $xTiF_6 \cdot yMF$. A few oxyhaloid compounds have been isolated, but a great number can doubtless be formed. The acid $H_2TiO_4F_6$ and salts of this acid have been isolated. $TiCl_3$ dissolves in water, and after a time $TiO_2 \cdot xH_2O$ separates; the solution is an energetic reducing agent; alkalis ppt. $Ti_2O_3 \cdot xH_2O$. $TiCl_3$ reacts violently with water, giving off H, and probably forming an oxychloride.

Titanium, hydroxyl chlorides of. By the reaction of the proper quantity of 36 p.c. $HClAq$ with $TiCl_3$, the compound $Ti(OH)Cl_2$ was obtained by Koenig a. O. v. d. Pfordten (*B.* 21, 1708); using the calculated quantity of 36 p.c. $HClAq$, the compound $Ti(OH)_2Cl_2$ was produced; and the prolonged action of ordinary air on either of the preceding compounds resulted in the formation of $Ti(OH)_2Cl$. These compounds are regarded by K. a. O. v. d. P. as derived from $Ti(OH)_3$ by replacement of OH by Cl; the compounds may be called *orthotitanic chlorhydrins*. The compounds are yellow or white deliquescent solids; they dissolve in water; $Ti(OH)Cl_2$ very rapidly with a hissing noise, $Ti(OH)_2Cl_2$ less violently, and $Ti(OH)_2Cl$ with some difficulty. The aqueous solutions give pps. of $TiO_2 \cdot xH_2O$ on boiling. When the compounds are heated they give (1) $TiCl_3$ and $TiO_2 \cdot xH_2O$, (2) $TiO_2 \cdot xH_2O$ and HCl , and (3) $TiO_2 \cdot xH_2O$, HCl , and H_2O . By reducing $Ti(OH)Cl_2$ by Na amalgam, in H_2 , Ti_2O_3 is produced (K. a. O. v. d. P., *B.* 22, 2070; cf. *B.* 22, 1485).

Titanium, hydroxyl fluoride of. This name may be given to the compound $Ti(OH)F_3$; it is described as *titanocyfluorhydric acid*, under TITANIC FLUORIDE (p. 742).

Titanium, iodides of. Only one compound has been isolated, TiI_4 .

TITANIC IODIDE TiI_4 . (*Titanium tetra-iodide*.) Mol. w. 554.02. V.D. at $440^\circ = 261.2$ (Hautefeuille, *Bl.* [2] 7, 201).

Formation.—1. Vapour of I is passed over Ti heated to redness (Weber, *P.* 120, 287).—2. A mixture of $TiCl_3$ vapour, I vapour, and H is passed through a tube heated to dull redness; TiI_4 , mixed with free I, condenses on the colder part of the tube (Hautefeuille, *Bl.* [2] 7, 201).—3. By decomposing $TiCl_3$ by HI.

Preparation.—Dry HI gas is passed into $TiCl_3$, which is gradually heated to its b.p. and kept at that temperature until the reaction is completed; the TiI_4 is freed from traces of I, which give it a violet tinge, by a few distillations in H (*H.*, *l.c.*).

Properties and Reactions.—A reddish-brown, lustrous, brittle solid; when melted and cooled, crystallises in octahedra, changing after some days to tufts of silky, prismatic crystals. Melts at 150° , and boils a little above 360° ; can be distilled without decomposition; melted TiI_4 remains liquid till cooled below 100° . Fumes strongly in the air. Dissolves easily in water; solution turns brown on exposure to air and ppts. $TiO_2 \cdot xH_2O$. When vapour of TiI_4 is heated in air it burns to TiO_2 and IO_2 (*H.*, *l.c.*).

Titanium, nitrides of. Four compounds of Ti and N have been described; but according to later experiments only two seem to exist.

TITANIUM TETRANITRIDE Ti_4N_4 . Mol. w. unknown. This compound is obtained by heating

$TiCl_3 \cdot 4NH_3$ (*v.* TITANIC CHLORIDE, *Combinations*, No. 2, p. 740), loosely packed in a tube of hard glass, in a stream of dry NH_3 , until the glass begins to melt, and allowing to cool in NH_3 (Wöhler, *A.* 73, 43; Friedel a. Guérin, *A. Ch.* [5] 8, 24). Indigo-blue powder, or golden-yellow (? rhombohedral) crystals; strongly heated in H gives Ti_3N_4 (*F. a. G.*, *l.c.*).

DITITANIUM DINITRIDE Ti_2N_2 . Mol. w. unknown. Prepared by placing two porcelain boats, one containing Na and the other K_2TiF_6 , in a hard-glass tube previously filled with N, passing a stream of dry N through the tube, heating the K_2TiF_6 to full redness while the Na is volatilised over it, and allowing to cool in N after all the Na has been volatilised; boiling with $HClAq$, washing, and drying (Wöhler a. Deville, *A.* 102, 284). Also obtained by heating K_2TiF_6 with K, KCl, NaCl, and Al in N; also by passing $TiCl_3$ vapour and H over heated Al in N; also by passing vapour of $TiCl_3$ over heated NH_4Cl (*W. a. D.*, *l.c.*). *F. a. G.* (*l.c.*) obtained the same compound by strongly heating TiO_2 in a stream of dry NH_3 for some hours; *W.* (*A.* 73, 43) said that TiN_2 was formed by this reaction. *F. a. G.* also obtained Ti_2N_2 by strongly heating Ti_3N_4 in H; *W.* said that Ti_3N_4 was formed by this reaction. An amorphous, brown-yellow, very hard powder; S.G. 5.28 at 18° (*F. a. G.*, *l.c.*).

The nitrides of Ti are not decomposed by heating, out of air, to c. 950° – $1,000^\circ$; fused with KOH, or strongly heated in steam (*F. a. G.*, *l.c.*), they give off NH_3 ; heated in Cl_2 , $TiCl_3$ is produced (*F. a. G.*, *l.c.*); heated with CuO, PbO, or HgO, the nitrides burn, and Cu, Pb, or Hg is produced (*W.*, *A.* 123, 84).

TITANIUM DINITRIDE Ti_2N_2 . This compound is formed, according to Wöhler (*A.* 73, 43), by heating TiO_2 in NH_3 for some time. Friedel a. Guérin (*A. Ch.* [5] 8, 24) say that the substance obtained by W. contained Ti_2O_3 , and that if the heating is continued until a definite nitride is formed the compound so produced is Ti_2N_2 .

PENTATITANIUM HEXANITRIDE Ti_5N_6 . Formed, according to *W.* (*l.c.*) by heating Ti_3N_4 to full redness in H; or, mixed with C, by heating TiO_2 in CN or HCN gas. *F. a. G.* (*l.c.*) say that the product of either reaction is Ti_5N_6 , in the latter reaction mixed with C.

Titanium, nitrocyanide of, *v.* TITANIUM CARBONITRIDE (p. 739).

Titanium, oxides and hydrated oxides of (*cf.* TITANIUM OXYACIDS AND SALTS AND DERIVATIVES THEREOF, p. 746). Ti burns when heated in O, forming TiO_2 ; by the reaction of reducing agents on $TiCl_3Aq$, and addition of alkalis, Ti_2O_3 is obtained; when the reduction is carried further it is probable that $TiO \cdot xH_2O$ is formed. By the reaction of H_2O_2Aq in presence of alkali on salts of TiO , a pp. of TiO_2 is obtained. Oxides intermediate between TiO_2 and Ti_2O_3 probably exist. TiO_2 is a basic oxide, forming salts TiX_2 , where $X = NO_3$, $\frac{1}{2}SO_4$, &c.; many of the salts are basic. A few salts corresponding with Ti_2O_3 have been isolated; no salt corresponding with TiO and derived from an oxyacid has yet been obtained. Some of the hydrates of TiO_2 react as feeble acids.

TITANIUM DIOXIDE TiO_2 . (*Titanic oxide. Titanic anhydride.*) Mol. w. unknown.

Occurrence.—As *rutile*, *anatase*, and *brookite*; *rutile* occurs in dimetric prisms, isomorphous with *tinstone*; *anatase* in dimetric octahedra; and *brookite* in trimetric octahedra.

Formation.—1. By burning Ti in air or O.—2. By ppg. TiCl_4 Aq by alkali, and washing, drying, and strongly heating the ppd. $\text{TiO}_2 \cdot x\text{H}_2\text{O}$.—3. By ppg. K_2TiF_6 Aq by NH_4Aq , and strongly heating the pp. after washing and drying.—4. Vapour of TiCl_4 , or TiF_4 , mixed with steam is passed through a red-hot tube.—5. TiS_2 is heated in dry CO_2 ($\text{TiS}_2 + 2\text{CO}_2 = \text{TiO}_2 + 2\text{CO} + 2\text{S}$; O. v. d. Pfordten, B. 22, 2070).

Preparation.—A. Amorphous titanio oxide.—1. Pure TiCl_4 is added, little by little, to water; sufficient NH_4Aq to neutralise the HCl produced is added, the solution is evaporated to dryness, and the residue is heated to somewhat above 700° until it ceases to lose weight. TiCl_4 may be obtained from *rutile* by mixing the finely-powdered mineral with c. half its weight of dry charcoal-powder, making into little pellets with starch-paste, drying the pellets, heating them to full redness in a covered crucible, then heating in a tube of hard glass (to get quite dry), and then passing dry Cl over the pellets while they are heated to bright redness, and a dry receiver is connected with the end of the hard glass tube. The TiCl_4 may be purified (from SiCl_4 , FeCl_3 , &c.) by repeatedly distilling, best in a stream of N (v. Merz, J. pr. 99, 161).—2. K_2TiF_6 is dissolved in water, NH_4Aq is added, the pp. of $\text{TiO}_2 \cdot x\text{H}_2\text{O}$ is thoroughly washed, dried, and heated to somewhat above 700° . (For a method of getting K_2TiF_6 from *rutile* v. *Preparation of titanium*, p. 788.) For other methods of preparing TiO_2 from Ti ores v. Lévy (A. Ch. [6] 25, 511), Austen a. Wilber (Am. J. 4, 211), Hempel (Zeit. f. anorg. Chemie, 8, 193), Jones (Fr. 9, 41, 380). B. Crystalline titanio oxide.—3. By long-continued heating to whiteness TiO_2 is said to become crystalline (v. Rammelsberg, B. 5, 1006).—4. Amorphous $\text{TiO}_2 \cdot x\text{H}_2\text{O}$ is heated to incipient redness in HCl gas, at a pressure of three atmospheres; the crystals have the form of *anatase* (Haute-feuille a. Perrey, C. R. 110, 1038).—5. Crystalline TiO_2 is also formed, according to Hautefeuille (A. Ch. [4] 4, 127), by passing the mixed vapours of TiF_4 , HF , and HCl —obtained by decomposing molten K_2TiF_6 by HCl gas—through a Pt tube into which a stream of moist H is also passed; at c. 860° (boiling-point of Cd) crystals of *anatase* are produced, and at temperatures between 860° and $1,000^\circ$ *brookite* is formed.—6. Heating amorphous TiO_2 in an atmosphere of HF causes crystallisation; at an incipient red heat *anatase* forms, at a higher temperature *brookite*, and at a very high temperature *rutile* (H., l.c.).—7. Crystals of *rutile* are formed by heating amorphous TiO_2 with microcosmic salt (Ebelmen, A. Ch. [8] 88, 84), or with borax (G. Roce, B. B. 1867, 129; Knop, A. 157, 865), in a porcelain oven. For other methods of producing crystals of TiO_2 v. Deville (C. R. 53, 161, 168), Senarmont (A. Ch. [8] 80, 129), Michel (C. R. 115, 1020), Wöhler (A. 78, 85), Daubrée (C. R. 29, 227; 89, 158), H. Rose (A. 56, 127; 68, 168).

Properties.— TiO_2 , obtained by strongly heating $\text{TiO}_2 \cdot x\text{H}_2\text{O}$ forms reddish-brown lumps, more nearly resembling *rutile* in colour and lustre the

higher the temperature to which it is heated. The dehydration by heat of $\text{TiO}_2 \cdot x\text{H}_2\text{O}$ is accompanied by the appearance of shades of colour from white, though grey and greenish, to black, according to Wagner (B. 21, 960); these colours are similar to those shown by *anatase*, *brookite*, and *rutile*. Nilson a. Pettersson (Z. P. C. 1, 38 note) prepared TiO_2 as a white powder with faintest yellow tinge, by decomposing TiCl_4 by NH_4Aq , evaporating, and heating to whiteness. When melted by the O-H flame the colour is blue to black. S.G. TiO_2 increases as the oxide is heated; heated to c. 700° S.G. is c. 3.95 (Karsten, S. 65, 894), after being very strongly heated S.G. rises to 4.25 (Ebelmen, J. 4, 15; 12, 14). S.G. of *anatase* is 3.75 to 3.9 (Breithaupt, J. 2, 730; Damour, J. 10, 666); S.G. of *brookite* is 4 to 4.2 (Rammelsberg, J. 2, 730; Beck, J. 8, 704); S.G. of *rutile* is c. 4.3 (Scheerer, P. 65, 296; Müller, J. 5, 847). After fusion in the O-H flame and cooling S.G. is 4.1, according to Hautefeuille (A. Ch. [4] 40, 140). S.H. 0° to $100^\circ = \cdot 1785$, 0° to $211^\circ = \cdot 1791$, 0° to $301^\circ = \cdot 1843$, 0° to $440^\circ = \cdot 1919$ (Nilson a. Pettersson, Z. P. C. 1, 27; TiO_2 prepared by decomposing TiCl_4 by NH_4Aq , evaporating to dryness, and heating to white heat). TiO_2 crystallises in dimetric prisms (*rutile*), dimetric octahedra (*anatase*), and trimetric octahedra (*brookite*); it is isomorphous with SnO_2 (Wunder, J. pr. [2] 2, 206). TiO_2 is somewhat hygroscopic, even after prolonged and intense heating (Thorpe, C. J. 47, 125). It is insoluble in water, and in all acids except conc. H_2SO_4 ; when powdered TiO_2 is heated with conc. H_2SO_4 until the excess of acid is removed, the solid thus produced dissolves in water. TiO_2 melts in the O-H flame. According to Moissan (C. R. 115, 1034), when heated in an electric furnace to c. 2500° TiO_2 forms black crystals of TiO .

Reactions.—1. According to Ebelmen (A. Ch. [3] 20, 394), TiO_2 is reduced to Ti_2O_3 by heating to redness in *hydrogen*; but O. v. d. Pfordten (A. 237, 201) says the product has the composition Ti_2O_{12} .—2. A mixture of TiO_2 and *magnesium* powder heated to redness in H gives MgTiO_3 , and a brown powder which is probably TiO (Winkler, B. 23, 2657).—3. A mixture of TiO_2 and *carbon* strongly heated in *chlorine* gives TiCl_4 .—4. By long-continued heating in dry *ammonia* Ti_3N_2 is formed (Friedel a. Guérin, A. Ch. [5] 8, 24).—5. The compound $\text{TiCl}_4 \cdot \text{PCl}_5$ is obtained by heating an intimate mixture of TiO_2 and *phosphorus pentachloride*, in the ratio $\text{TiO}_2:3\text{PCl}_5$, in a retort until the POCl_3 formed is driven off (Weber, P. 132, 452).—6. Heated to redness in *carbon tetrachloride* vapour, TiCl_4 is formed (Watts a. Bell, C. J. 83, 443). Demarcay (C. R. 104, 111) says that the first product is TiOCl_2 .—7. TiCl_4 is formed by heating TiO_2 to redness in a mixture of equal volumes of *chlorine* and *carbon monoxide* (W. a. B., l.c.).—8. Ti_3N_2 mixed with C is formed by heating TiO_2 in *cyanogen* or in *hydrogen cyanide* (Friedel a. Guérin, A. Ch. [5] 8, 24).—9. Heating in a mixture of *hydrogen sulphide* and *carbon disulphide* forms TiS_2 or TiS , according to the temperature (Thorpe, C. J. 47, 491).—10. When TiO_2 is fused with *sodium* or *potassium carbonate* the weight of CO_2 expelled corresponds with the formation of M_2TiO_4 ; on treating the fused mass

with water MOHAq is formed, and an acid Na or K titanate which is insoluble in water (v. Hermann, *J. pr.* 38, 92).—11. Fusion with *potassium hydrogen sulphate* forms a substance soluble in water; by evaporating the fused mass with conc. H_2SO_4 , and then treating with water, the double salt $Ti(SO_4)_2 \cdot K_2SO_4 \cdot 3H_2O$ is obtained (Warren, *P.* 102, 449; Glatzel, *B.* 9, 1833; Hermann, *l.c.*).—12. Heating powdered TiO_2 with conc. *sulphuric acid* produces a substance that dissolves wholly in water (? forming $Ti(SO_4)_2 \cdot xH_2O$ or $TiO \cdot SO_3$; v. Merz, *J. pr.* 99, 157). For reactions of $TiO_2 \cdot xH_2O$ v. *infra*, *hydrated titanous oxide*; and v. also *titanic acid* under TITANIUM OXYACIDS AND SALTS AND DERIVATIVES THEREOF, p. 746).

HYDRATED TITANIC OXIDE. Hydrates of TiO_2 are obtained by gradually adding $TiCl_4$ or $TiBr_4$ to cold NH_4Aq ; by fusing TiO_2 with $KHSO_4$, dissolving in water, diluting, and boiling for some time; by adding water to $TiCl_4$ and boiling; by fusing TiO_2 with K_2CO_3 , washing the fused mass with small quantities of water till all KOH is removed, adding a little conc. $HClAq$, filtering cold, and allowing the liquid to stand, when it gradually deposits gelatinous $TiO_2 \cdot xH_2O$ (O. v. d. Pfordten, *B.* 17, 727); by decomposing $Ti(OEt)_4$ by H_2O (Demarçay, *C. R.* 80, 51); and by other reactions. The isolation of a great many definite hydrates of TiO_2 has been announced from time to time. By decomposing $TiCl_4 \cdot PCl_5$ (v. TITANIUM CHLORIDE, *Combinations*, No. 6, p. 740) by the action of moist air, and drying over H_2SO_4 , Tütschschaff (*A.* 141, 111) said that the *dihydrate* $TiO_2 \cdot 2H_2O$ was formed, and by drying this at 110° – 120° he said that the *monohydrate* $TiO_2 \cdot H_2O$ was obtained. According to Carnelley a. Walker (*C. J.* 53, 66, 81), dehydration of $TiO_2 \cdot xH_2O$ (obtained by adding $TiCl_4$ to cold NH_4Aq), air-dried for 14 days, proceeds continuously from 15° to 710° whereat the whole of the water is removed. A very large number of hydrates probably exists, and these pass one into the other as temperature rises without any of them remaining unchanged through more than a few degrees.

Two classes of hydrates of TiO_2 exist; one obtained by ppg. $TiCl_4$ by NH_4Aq , or warming TiO_2 with conc. H_2SO_4 , dissolving in water, diluting, and ppg. by alkali; the other obtained by dissolving hydrates of the former class in dilute acid, and boiling. Hydrates of the former class dissolve easily in dilute acids, while those of the latter class are insoluble in dilute acids (for more details v. TITANIUM OXYACIDS, p. 746).

Hydrated TiO_2 , obtained by ppg. by alkali in the cold, dissolves in dilute acids, forming salts TiX_n , where $X = NO_3, \frac{1}{2}SO_4$, &c.; not many salts of this form have been isolated, and most of those that are known are basic salts. $TiO_2 \cdot xH_2O$ dissolves in molten H_3PO_4 ; on cooling crystals of $TiO_2 \cdot P_2O_5$ (= TiP_2O_7) are obtained (Haute-feuille a. Margottet, *C. R.* 102, 1017). By heat- $TiO_2 \cdot xH_2O$ with a little cold conc. $HClAq$, pouring off the solution after a few days, and evaporating it in *vacuo*, Koenig a. O. v. d. Pfordten obtained crystals approximating to $Ti(OH)_2Cl_2$, but differing from $Ti(OH)_2Cl_2$ prepared by the interaction of $TiCl_4$ and $HClAq$ (*B.* 22, 1485; cf. TITANIUM HYDROXYL CHLORIDES, p. 748).

TITANIUM SESQUIOXIDE Ti_2O_3 . (*Titanous*

oxide.) Mol. w. unknown. By digesting a solution of $TiO_2 \cdot xH_2O$ in $HClAq$ with Cu at 40° to 50° , Fuchs (*A.* 56, 319) obtained a violet solution which gave a brownish black pp. with NH_4Aq ; the pp. quickly reacted with water, giving off H and forming $TiO_2 \cdot xH_2O$. Von Kobell (*P.* 62, 599) obtained similar reactions by using reduced Ag in place of Cu. Ebelmen (*J. pr.* 42, 78) obtained a nearly black pp. by adding alkali to Ti_2Cl_4Aq . According to Ebelmen (*J. pr.* 42, 76) Ti_2O_3 can be prepared by heating TiO_2 to redness in perfectly dry H. Ti_2O_3 thus prepared is described as a black solid; unacted on by HNO_3 or $HClAq$; oxidised to TiO_2 only by heating to a very high temperature; soluble in H_2SO_4Aq , forming a violet solution. According to O. v. d. Pfordten (*A.* 237, 201), the product of reducing TiO_2 in H is not Ti_2O_3 , but has the composition Ti_3O_{12} . Friedel a. Guérin (*A. Ch.* [5] 8, 88) obtained Ti_2O_3 , but not free from other compounds, by passing $TiCl_4$ vapour mixed with H over TiO_2 at a red heat. They describe Ti_2O_3 as a copper-red, metal-like, microscopically crystalline powder; not acted on by boiling HNO_3Aq , but oxidised to $TiO_2 \cdot xH_2O$ by boiling H_2SO_4Aq ; soluble in $HFAq$ or warm *aqua regia*; giving off NH_3 and H with hot alkali solutions; oxidised to TiO_2 by heating to redness in air. Koenig a. O. v. d. Pfordten (*B.* 22, 2070) failed to obtain Ti_2O_3 by the method of F. a. G.

When Ti is dissolved in hot $HClAq$, in an atmosphere of H, the solution contains Ti_2Cl_4 (Rammelsberg, *J. pr.* 99, 176); a solution of $TiO_2 \cdot xH_2O$ in $HClAq$ reduced by zinc also contains Ti_2Cl_4 (K. a. O. v. d. P., *l.c.*); in these solutions alkalis give black pps., probably $Ti_2O_3 \cdot xH_2O$; the pps. soon change in contact with H_2O to $TiO_2 \cdot xH_2O$, H being given off. According to O. v. d. P. (*A.* 237, 201), a solution of K_2TiF_6 in a little $HClAq$ gives a pp. of $Ti_2O_3 \cdot xH_2O$ on treatment with Na-amalgam.

Sabatier a. Senderens (*C. R.* 114, 1429; 115, 236) say that Ti_2O_3 is oxidised to TiO_2 by heating to c. 500° in NO, or to c. 300° in NO_2 .

TITANIUM MONOXIDE TiO . This oxide has not been isolated with certainty. According to Moissan (*C. R.* 115, 1034) black prisms, which he took to be TiO , are formed by heating TiO_2 to c. 2500° in an electric furnace, and at a higher temperature the (?) TiO melts and then volatilises. By heating a mixture of TiO_2 and Mg powder to redness, in H, Winkler (*B.* 23, 2657) obtained a brown powder which probably contained some TiO , mixed with $MgTiO_3$. According to Berthier (*A. Ch.* [2] 54, 374) TiO , lost 6 p.c. O when heated strongly in a carbon crucible, 13 to 16 p.c. O when heated with 12 p.c. O, and 20 p.c. O when heated with 24 p.c. O (TiO loses 20 p.c. O in becoming TiO_2); the product may have contained Ti_2O_3 , or it may have been a mixture of TiO , Ti_2O_3 , and Ti .

HYDRATED TITANIUM MONOXIDE

$TiO \cdot H_2O = TiOH_2$. O. v. d. Pfordten (*A.* 237, 201) obtained a black pp., said by him to be $TiOH_2$, by the continued action of Na-amalgam on a solution of K_2TiF_6 in a fair amount of $HClAq$ (if there is little $HClAq$, Ti_2O_3 is ppg.); the solution became green, then colourless, and then the black pp. was formed. The black pp. formed by NH_4Aq , alkali carbonates, or $(NH_4)_2SAq$, in solutions of $TiCl_4$ (q. v., p. 741) is $TiO \cdot H_2$, according

to O. v. d. P. (l.c.). With $\text{Na}_2\text{HPO}_4\text{Aq.}$ and $\text{Na}_2\text{C}_2\text{H}_3\text{O}_4\text{Aq.}$ TiCl_3 is said to give bluish-black and greenish-black pps., which may be salts of TiO (O. v. d. P., l.c.).

TITANIUM PEROXIDE. TiO_2 . (*Titaniumtrioxide* or *superoxide*.) In 1882 (*Atti dei Lincei*, 1882.

1) Piccini dropped $\text{H}_2\text{O}_2\text{Aq.}$ into solution of $\text{TiO}_2 \cdot x\text{H}_2\text{O}$; from the quantity of H_2O_2 that reacted he concluded that an oxide TiO_2 was produced. In the same year (B. 15, 2599) Weller obtained a yellow pp., which reacted with HClAq. giving off Cl , by the interaction of $\text{H}_2\text{O}_2\text{Aq.}$ and freshly ppd. $\text{TiO}_2 \cdot x\text{H}_2\text{O}$ or a solution of $\text{TiO}_2 \cdot x\text{H}_2\text{O}$. In 1888, Classen (B. 21, 370) added TiCl_3 drop by drop, to dilute alcohol, then added to this solution a very large excess of $\text{H}_2\text{O}_2\text{Aq.}$ and then KOH Aq. , $\text{NH}_3\text{Aq.}$ or $(\text{NH}_4)_2\text{CO}_3\text{Aq.}$; in each case he obtained a yellow liquid from which a yellow pp. separated after some time; after syphoning off the liquid, washing the pp. by decantation, and drying it on a tile, he obtained a yellow solid approximating to the composition $\text{TiO}_2 \cdot 3\text{H}_2\text{O}$. In 1889, Lévy (C. R. 108, 294) approximately determined the composition of the pp. obtained by adding $\text{H}_2\text{O}_2\text{Aq.}$ to $\text{TiO}_2 \cdot x\text{H}_2\text{O}$ in $\text{H}_2\text{SO}_4\text{Aq.}$ by dropping in $\text{H}_2\text{O}_2\text{Aq.}$ of known concentration, and determining the quantity of H_2O_2 used in the reaction; L. concluded that the results could be accounted for by supposing the yellow pp. to be TiO_2 , $\text{TiO}_2 \cdot \text{H}_2\text{O}$, or $\text{Ti}_2\text{O}_3 \cdot \text{H}_2\text{O}$, but that probably the pp. was TiO_2 . In 1893 Bailey a. Dawson (*Studies from the Phys. and Chem. Laboratories of the Owens College*, vol. i. p. 216) obtained yellow to orange solids, agreeing fairly in composition with the formula TiO_2 . B. a. D. added (1) $\text{H}_2\text{O}_2\text{Aq.}$ (2) freshly ppd. BaO_2 to $\text{TiO}_2 \cdot x\text{H}_2\text{O}$ in dilute $\text{H}_2\text{SO}_4\text{Aq.}$ diluted the deep-red liquids thus obtained with twice their volumes of alcohol, added conc. alcoholic solution of KOH , washed the pps. with alcohol (to remove H_2O and H_2O_2), and then with ether, and, in some cases, dried in the air. According to B. a. D., TiO_2 dissolves in water, forming a deep-red liquid; this solution decolourises $\text{KMnO}_4\text{Aq.}$; TiO_2 dissolves in HClAq. giving off Cl . By allowing ppd. TiO_2 to stand for some time, B. a. D. say that a modification is formed insoluble in water.

OXIDES OF TITANIUM INTERMEDIATE BETWEEN TiO_2 AND Ti_2O_3 .

I. By heating TiO_2 with HCl gas in a reducing atmosphere, Deville (C. R. 53, 163) obtained a blue, crystalline solid, to which he gave the formula Ti_2O_3 . A similar solid (? same composition) was obtained by Friedel a. Guérin (A. Ch. [5] 8, 44) by passing H and HCl over TiO_2 strongly heated in a porcelain tube. This blue solid is said to decompose water, in presence of strong bases, giving off H and forming TiO_2 .

II. By very strongly heating TiO_2 in H , O. v. d. Pfordten (A. 237, 228) obtained a dark indigo-blue solid, to which he gave the formula Ti_2O_3 ; according to Ebelmen (J. pr. 42, 76), Ti_2O_3 is formed by this reaction. Heated in air the compound burns to TiO_2 .

III. By adding alcoholic solution of KOH to a solution of $\text{TiO}_2 \cdot x\text{H}_2\text{O}$ in dilute $\text{H}_2\text{SO}_4\text{Aq.}$ after treating the solution with BaO_2 Piccini (*Atti dei Lincei*, 1882. 1) obtained yellow pps. with compositions varying from Ti_2O_3 to TiO_2 .

Titanium oxyacids and salts and derivatives thereof. The hydrates of TiO_2 react as feeble acids, besides reacting with the stronger acids as feeble bases. The salts wherein Ti forms part of the acidic radicles are generally obtained by fusing TiO_2 with salts of the metals which are to be converted into titanates. Only a very few titanates are soluble in water; several dissolve in HClAq. but on diluting and boiling most, if not all, of the $\text{TiO}_2 \cdot x\text{H}_2\text{O}$ is ppd.

TITANIC ACIDS. Hydrates of TiO_2 are obtained by various reactions (v. HYDRATED TITANIC OXIDE, p. 745). By drying under different conditions solids are obtained approximately corresponding with the formula $x\text{TiO}_2 \cdot y\text{H}_2\text{O}$, where $x=1, 2$, or 3 , and $y=1, 2, 3, 4$, or 5 . (For a list of the hydrates obtained by different experimenters v. Tüttscheff, A. 141, 111.) There seems to be a series of hydrates of TiO_2 , all of which may be classed together under the name *titanic acids*, none of them being stable through more than a few degrees of temperature (v. Carnelley a. Walker, C. J. 53, 66, 81); the relations of composition of these acids may be expressed by such a general equation as $n\text{TiH}_2\text{O}_4 - m\text{H}_2\text{O} = \text{Ti}_n\text{H}_{4n-2m}\text{O}_{4n-m}$.

The titanic acids belong to two classes: those which are formed by decomposing TiCl_3 or TiBr_3 by dilute cold alkali solutions, or by warming TiO_2 with conc. H_2SO_4 , dissolving the product in water, and ppg. by dilute cold alkali solutions; and those which are formed by decomposing TiCl_3 or TiBr_3 by water and boiling, or by dissolving titanic acids of the former class in dilute acid and boiling, or by fusing TiO_2 with KHSO_4 , dissolving in much water and boiling. The acids of the former class are generally called *titanic acids* or *ortho-titanic acids*, and those of the latter class *meta-titanic acids*. *Orthotitanic acids* dissolve easily in dilute acids; *metatitanic acids* are insol. dilute acids; by prolonged heating with conc. H_2SO_4 compounds are produced which dissolve on adding water. *Meta-acids* are also formed by heating *ortho-acids* to c. 100° . Experiments made by Merz (J. pr. 99, 166) show that the *meta-acids* lose water, on heating, more easily than the *ortho-acids*.

ORTHOTITANIC ACIDS. According to Wagner (B. 21, 960), a clear solution of an orthotitanic acid is obtained by adding water, a drop at a time, to TiCl_3 , with constant shaking; HCl and TiCl_3 are given off (by the heat of the reaction), a solid is produced, then a greenish-yellow liquid, and finally a clear solution. By adding 1 pt. TiCl_3 to c. 6 to 7 pts. water, Thorpe (C. J. 47, 120) obtained an opalescent liquid which became clear after standing for 40 hours, and then contained orthotitanic acid; when this solution was heated ppn. of metatitanic acids began at c. 87° , and at c. 90° most of the Ti was ppd. A solution of TiBr_3 in water forms a perfectly clear liquid containing ortho-acid (T., l.c., p. 126). The white flocculent solid obtained by adding TiCl_3 to dilute HClAq. ppg. by $\text{NH}_3\text{Aq.}$ when cold, washing with cold water, and drying in the air is $\text{TiO}_2 \cdot 2\text{H}_2\text{O}$ ($= \text{TiO}(\text{H})_2$), according to Merz (J. pr. 99, 166); this composition is also assigned to the solid formed by keeping $\text{TiCl}_3 \cdot \text{PCl}_5$ under a bell-jar, with water and CaO , for some days, and then drying over H_2SO_4 (Tüttscheff, A. 141, 111). When $\text{TiO}(\text{H})_2$ is dried *in vacuo* (Tüttscheff, l.c.), or over H_2SO_4 ,

(Merz, *l.c.*), the product is said to be $\text{TiO}_2 \cdot \text{H}_2\text{O}$ ($= \text{H}_2\text{TiO}_4 = \text{TiO}_2 \cdot \text{O}_2\text{H}_2$). The composition $2\text{TiO}_2 \cdot \text{H}_2\text{O}$ ($= \text{H}_2\text{Ti}_2\text{O}_5 = \text{Ti}_2\text{O}_5 \cdot \text{O}_2\text{H}_2$) is given to the product dried at 100° (Merz, *l.c.*; Demoly, *C. R.* 1849, 326), dried at 140° (Tütttscheff, *l.c.*), or dried *in vacuo* over H_2SO_4 (H. Rose, *A.* 52, 268); after drying at 100° or upwards, *meta-acids* are probably produced.

Orthotitanic acids are insoluble in water or alcohol; but dissolve easily in dilute acids; said also to dissolve in alkali carbonate solutions. The solutions in acids probably contain salts of the type TiX_x , $\text{X} = \text{Cl}, \text{NO}_3, \frac{1}{2}\text{SO}_4$, &c.; but compounds of the form $\text{Ti}(\text{OH})_x\text{X}_y$, where X is a monovalent acidic radicle, and x is not greater than 3, may be formed, similar to the compounds $\text{Ti}(\text{OH})_2\text{Cl}$, $\text{Ti}(\text{OH})_2\text{Cl}_2$, and $\text{Ti}(\text{OH})\text{Cl}_3$, obtained by O. v. d. Pfordten by the interaction of HClAq and TiCl_3 (*B.* 21, 1708; *v. TITANIUM HYDROXYL CHLORIDES*, p. 753). By adding a little conc. cold HClAq to orthotitanic acid, allowing to stand for some days, pouring off the clear liquid from undissolved acid, and evaporating *in vacuo*, Koenig a. O. v. d. P. (*B.* 22, 1485) obtained a white solid containing Ti and Cl in the ratio 1:1.47; they regarded this as consisting chiefly either of $\text{TiCl}_2(\text{OH})_2$ —but different in some properties from $\text{TiCl}_2(\text{OH})_2$, obtained from TiCl_3 —or chiefly of $\text{TiCl}(\text{OH})_2 \cdot \text{HCl}$. White pps. are obtained by adding $\text{H}_3\text{PO}_4\text{Aq}$, $\text{H}_2\text{AsO}_4\text{Aq}$, or $\text{H}_2\text{C}_2\text{O}_4\text{Aq}$ to solutions of orthotitanic acids in dilute HClAq , HNO_3Aq , or $\text{H}_2\text{SO}_4\text{Aq}$, after making nearly neutral by NH_3Aq . When acid solutions of orthotitanic acids are diluted considerably and boiled for some time the whole of the Ti is ppd. as meta-acids. Ortho-acids are also partly changed to meta-acids by keeping under water for a long time (Wagner, *B.* 21, 960), or by washing with hot water. When an orthotitanic acid is heated strongly TiO_2 is produced, with vivid incandescence; the change from a meta-acid to TiO_2 is not accompanied by incandescence. According to Wagner (*l.c.*), the dehydration of moist ortho-acids by gently warming is accompanied by changes of colour from white to grey, green, and black.

METATITANIC ACIDS. Formed, as white powders, by dissolving ortho-acids in dilute acid and boiling for some time; also by fusing TiO_2 with KHSO_4 and boiling with much water; also by adding water to TiCl_3 or TiBr_3 and boiling; also by oxidising Ti by HNO_3 , S.G. 1.25 (Weber, *P.* 120, 287). According to Weber (*l.c.*), freshly prepared dilute TiCl_3Aq is not rendered turbid by HClAq , HNO_3Aq , or $\text{H}_2\text{SO}_4\text{Aq}$, but these acids at once ppt. metatitanic acids when added to dilute TiCl_3Aq that has been boiled even for a few seconds. The pp. obtained by boiling a diluted solution of an orthotitanic acid in dilute H_2SO_4 is said to have the composition $\text{TiO}_2 \cdot 2\text{H}_2\text{O}$ ($= \text{TiO}_2 \cdot \text{H}_2\text{O}$) when dried over H_2SO_4 , the composition $3\text{TiO}_2 \cdot 4\text{H}_2\text{O}$ ($= \text{Ti}_3\text{O}_{10} \cdot \text{H}_2\text{O} = \text{Ti}_3\text{O}_9 \cdot \text{O}_2\text{H}_2$) when dried at 120° , and the composition $3\text{TiO}_2 \cdot 2\text{H}_2\text{O}$ ($= \text{Ti}_3\text{O}_8 \cdot \text{H}_2\text{O} = \text{Ti}_3\text{O}_7 \cdot \text{O}_2\text{H}_2$) when dried at 140° (Tütttscheff, *A.* 141, 111); Merz (*J. pr.* 99, 166) gives the composition $\text{TiO}_2 \cdot \text{H}_2\text{O}$ ($= \text{TiO}_2 \cdot \text{H}_2\text{O} = \text{TiO}_2 \cdot \text{O}_2\text{H}_2$) to the air-dried pp., and the composition $2\text{TiO}_2 \cdot \text{H}_2\text{O}$ ($= \text{Ti}_2\text{O}_5 \cdot \text{H}_2\text{O} = \text{Ti}_2\text{O}_4 \cdot \text{O}_2\text{H}_2$) to the pp. dried over H_2SO_4 , or at 60° .

Metatitanic acids are white powders, insoluble

in water or dilute acids; after heating with conc. H_2SO_4 the products dissolve in water; when strongly heated TiO_2 is formed without incandescence.

COLLOIDAL TITANIC ACIDS. Graham (*T.* 1861, 213) obtained a gelatinous, probably orthotitanic, acid, insoluble in water, by dialysing a solution of $\text{TiO}_2 \cdot x\text{H}_2\text{O}$ in HClAq ; by dissolving this gelatinous acid in such a quantity of cold dilute HClAq that not more than 1 p.c. titanic acid was present in the solution, and dialysing for several days, G. (*O. J.* 17, 325) obtained a dilute aqueous solution of colloidal titanic acid. Colloidal, insoluble, titanic acids have also been prepared by Knop (*A.* 123, 351), Rose (*G. A.* 73, 76 [1823]), and O. v. d. Pfordten (*B.* 17, 727).

TITANATES. These salts have not been thoroughly investigated. Those which have been best examined are either derivatives of H_2TiO_4 or H_2TiO_3 , or are basic salts of the type $x\text{MO} \cdot \text{TiO}_2$, where $x > 1$. Some acid salts $\text{MO} \cdot x\text{TiO}_2$, where $x > 1$, are also known. The older investigations were made chiefly by H. Rose (*P.* 61, 507) and by Hautefeuille (*A. Ch.* [2] 4, 129).

Barium titanates. An acid salt $2\text{BaO} \cdot 3\text{TiO}_2$ ($= 2\text{Ba} \cdot \text{TiO}_3 \cdot \text{TiO}_2$ or $\text{Ba}_2 \cdot \text{TiO}_3 \cdot 2\text{TiO}_2$) was obtained by Bourgeois (*C. R.* 103, 141) in lustrous microscopic crystals, by heating to full redness a mixture of equivalent parts of TiO_2 and BaCO_3 , with excess of BaCl_2 , and washing with very dilute HClAq .

Calcium titanates. The normal salt CaTiO_3 , occurs native as *perowskite*. The same salt was formed by heating to bright redness a mixture of equivalent parts of TiO_2 and CaCO_3 , with excess of CaCl_2 , and washing with very dilute HClAq (Bourgeois, *l.c.*).

Iron titanates. The mineral *titaniferous iron* or *ilmenite* is more or less pure $x\text{Fe}_2\text{O}_3 \cdot y\text{TiO}_2$. By fusing a mixture of 2 pts. TiO_2 and 5 pts. FeFe , with a large excess of NaCl , washing with water, and then with very dilute acid, Hautefeuille (*C. R.* 59, 733) obtained dark purple-violet, lustrous crystals of *ferrous titanate* Fe_2TiO_5 ($= 2\text{FeO} \cdot \text{TiO}_2$); but according to Koenig a. O. v. d. Pfordten (*B.* 22, 1485) the salt produced is *ferric titanate* $\text{Fe}_3(\text{TiO}_4)_2$ ($= 2\text{Fe}_2\text{O}_3 \cdot 3\text{TiO}_2$). K. a. O. v. d. P. say that the salt dissolves in water after warming with conc. H_2SO_4 , forming a green solution containing $\text{Fe}_2(\text{SO}_4)_3$ and titanic acid.

Magnesium titanates. The normal salt MgTiO_3 ($= \text{MgO} \cdot \text{TiO}_2$) was obtained (by Hautefeuille, *l.c.*) by heating to whiteness, for a short time in a closed crucible, a mixture of 1 pt. TiO_2 and 10 pts. MgCl_2 with a little NH_4Cl , washing with extremely dilute acetic acid, and then with water; lustrous, six-sided (probably trimetric) crystals, S.G. 3.91. The same salt is formed, according to Winkler (*B.* 23, 2657), by heating a mixture of TiO_2 and Mg powder. By heating a mixture of 2 pts. TiO_2 , 1 pt. MgO , and 40 pts. MgCl_2 , and washing with very dilute acetic acid, the salt Mg_2TiO_5 ($= 2\text{MgO} \cdot \text{TiO}_2$) is said to be formed in hard, lustrous, regular octahedra, S.G. 3.42 (H.).

Potassium titanates. When TiO_2 is fused with excess of K_2CO_3 , the quantity of CO_2 given off corresponds with the formation of the

normal salt K_2TiO_3 ; after fusion two layers are obtained, the lower of which is said to consist of K_2TiO_3 , while the upper contains the undecomposed K_2CO_3 . K_2TiO_3 is described as a yellowish, fibrous, easily fused solid (H. Rose, *P.* 61, 507). Water resolves it (according to Rose) into an insoluble *acid salt*, and a soluble *basic salt*; but according to Hermann (*J. pr.* 38, 92) no trace of titanous acid goes into solution in water, but all remains in the insoluble acid salt.

Sodium titanates. The *normal salt* Na_2TiO_3 was obtained by H. Rose (*l.c.*) similarly to the K salt; water resolves it into an insoluble *acid salt* and $NaOHAq$. By heating Na_2WO_3 , and in some cases also WO_3 , with mixtures of TiO_2 and Na_2CO_3 previously fused, Cormimbœuf (*C. R.* 115, 823) obtained three *acid salts*:

(1) $2Na_2O \cdot 3TiO_2$ ($= 2Na_2TiO_3 \cdot TiO_2$, or $Na_2TiO_3 \cdot 2TiO_2$), (2) $Na_2O \cdot 2TiO_2$ ($Na_2TiO_3 \cdot TiO_2$, or $Na_2Ti_2O_5$), (3) $Na_2O \cdot 3TiO_2$ ($= Na_2TiO_3 \cdot 2TiO_2$, or $Na_2Ti_3O_7$).

Strontium titanates. An *acid salt* $2SrO \cdot 3TiO_2$ ($= 2SrTiO_3 \cdot TiO_2$ or $Sr_2TiO_3 \cdot 2TiO_2$) was obtained, in pale-greenish-yellow cubes, S.G. 5.1, by Bourgeois (*C. R.* 103, 141), by heating equivalent parts of TiO_2 and $SrCO_3$ with excess of $SrCl_2$, and washing with very dilute $HClAq$.

Zinc titanates. The *normal salt* $ZnTiO_3$ was obtained by Lévy (*C. R.* 107, 421), by heating to redness a mixture of 2 pts. TiO_2 , 8 pts. $ZnSO_4$, and 3 pts. K_2SO_4 , and washing with dilute $HClAq$; pale-violet, silky needles, S.G. 3.17, scarcely acted on by boiling conc. acids or conc. $KOHAq$. By varying the proportion of TiO_2 , $ZnSO_4$, and K_2SO_4 used, L. (*l.c.*) obtained the *normal salt* $ZnTiO_3$, which may also be regarded as a *basic salt* $ZnTiO_3 \cdot ZnO$; the *basic salt* $3ZnO \cdot 2TiO_2$ ($= 2ZnTiO_3 \cdot ZnO$); and the *acid salt* $4ZnO \cdot 5TiO_2$ ($= 4ZnTiO_3 \cdot TiO_2$).

FLUOTITANATES; v. *Titanifluorides*, under **TITANIC FLUORIDE**, *Combinations*, No. 2 (p. 742).

FLUOROXYTITANATES; v. *Titanoxylfluorides*, under **TITANIC FLUORIDE** (p. 742).

MOLYBDOTITANATES. A few compounds of the form $TiO_2 \cdot 12MoO_3 \cdot 2M_2O \cdot xaq$, where $M = NH_4$ and K , are described by Péchard (*C. R.* 117, 788). By shaking with ether a solution of the NH_4 salt, acidified by $HClAq$, and allowing the ethereal liquid to evaporate, P. (*l.c.*) obtained *molybdotitanic acid* $TiO_2 \cdot 12MoO_3 \cdot 22aq$, in golden yellow octahedra, melting at c. 60° , very soluble in water.

OXALOTTITANATES. By dissolving $TiO_2 \cdot xH_2O$ in hot KHC_2O_4Aq and cooling, Péchard (*C. R.* 116, 1513) obtained triclinic crystals of $2KHC_2O_4 \cdot TiO_2 \cdot H_2O$. By treating a solution of this salt with $BaCl_2Aq$, crystals of $Ba(HC_2O_4)_2 \cdot TiO_2 \cdot H_2O$ were obtained; and by decomposing this by an equivalent quantity of dilute H_2SO_4Aq , filtering, and evaporating *in vacuo*, long needles of *oxalotitanic acid* $2H_2C_2O_4 \cdot TiO_2 \cdot 2H_2O$ were obtained.

SILICOTITANATES; v. this heading, p. 464.

Titanium, oxychlorides of. Several oxychlorides are known. (1) $TiOCl$. According to Demarçay (*C. R.* 104, 111), this is the first product of heating TiO_2 and CCl_4 in a sealed tube; it is described as a yellow crystalline solid. Heated with CCl_4 it gives $TiCl_3$ and $COCl_2$.

(2) $TiOCl$. Obtained by passing a mixture of $TiCl_4$ vapour and dry H over TiO_2 in a tube heated white hot; Ti_2O_3 and Ti_2O_4 are also produced in the reaction (Friedel a. Guérin, *Bl.* [2] 22, 481). Brown, orthorhombic leaflets; heated in air burns to TiO_2 and $TiCl_4$. (3) $Ti_2O_3Cl_2$. Formed by passing $TiCl_4$ vapour through a red-hot tube containing fragments of porcelain (Troost a. Hautefeuille, *C. R.* 73, 563). (4) By allowing $TiCl_4$ to deliquesce in air, and then evaporating over H_2SO_4 and CaO , Merz (*Bl.* [2] 7, 401) obtained a solid approximating in composition to $Ti_2O_3Cl_2 \cdot 16H_2O$. In connection with oxychlorides cf. **TITANIUM HYDROXYL CHLORIDES** (p. 743).

Titanium, oxyfluoride of. By decomposing by water the crystals formed by dissolving $TiO_2 \cdot xH_2O$ in $HFAq$ and evaporating, Berzelius (*P.* 4, 1) obtained a white solid, of which he said it was an insoluble, 'so to say, *basic*,' compound.

The *titanoxylfluorides* $TiO_2F_2 \cdot 2MF$ may be regarded as compounds of the oxyfluoride TiO_2F_2 , (v. **TITANIC FLUORIDE**, p. 742).

Titanium, oxythiochloride of. The compound $TiCl_4 \cdot OSO_2Cl$ formed by the reaction of $TiCl_4$ with $SO_2 \cdot OH \cdot Cl$ may be regarded as $TiO_3S_2Cl_2$, (v. **TITANIC CHLORIDE**, *Reactions*, No. 10, p. 740).

Titanium, salts of. Not many salts have been prepared by replacing H of oxyacids by Ti ; most of those that have been isolated are basic salts derived from the oxide TiO_2 . One salt, $Ti_2(SO_4)_3$, corresponding with the oxide Ti_2O_3 has been isolated. For the individual salts v. **NITRATES**, vol. iii. p. 517; **PHOSPHATES**, this vol. p. 112, TiP_2O_7 , prepared by dissolving $TiO_2 \cdot xH_2O$ in molten H_3PO_4 (Hautefeuille a. Margottet, *C. R.* 102, 1017) should be added; and **SULPHATES**, this vol. p. 580.

Titanium, sulphides of. Three compounds of Ti and S have been isolated: TiS_2 , Ti_2S_3 , and TiS , corresponding with the three oxides TiO_2 , Ti_2O_3 , and TiO .

TITANIUM DISULPHIDE TiS_2 . (*Titanic sulphide*.) Mol. w. unknown. H. Rose (*P.* 8, 177) said that this compound was obtained by passing vapour of CS_2 over very strongly heated TiO_2 ; but O. v. d. Pfordten (*B.* 17, 727) and Thorpe (*C. J.* 47, 491) have found that it is not possible by this method to obtain TiS_2 free from Ti oxides. TiS_2 is prepared by passing perfectly dry H_2S into $TiCl_4$ kept somewhat below its b.p., and sending the mixed vapours through a glass tube heated to incipient redness; TiS_2 deposits in the tube, and HCl is given off (Ebelmen, *A. Ch.* [8] 20, 285; confirmed by O. v. d. Pfordten, *B.* 17, 727). According to O. v. d. P. (*A.* 234, 257), the H_2S should be passed through $CrCl_3Aq$ to remove traces of O , and dried by means of P_2O_5 ; and the tube should be filled with H_2S before the mixed vapours are passed into it.

TiS_2 forms large, brass-yellow, lustrous, metal-like scales.

TiS_2 is decomposed to TiS , and S by heating in *hydrogen or nitrogen*; it is not changed by heating in *hydrogen in presence of excess of hydrogen sulphide*; heated to redness in *carbon dioxide* it is completely oxidised to TiO_2 (O. v. d. P., *A.* 234, 257). Ebelmen (*l.c.*) gives the following reactions: with dry *chlorine* gives $TiCl_4$ and S_2Cl_2 ; heated *in air*, TiS_2 is burnt to

TiO_2 and SO_2 ; exposure to moist air decomposes TiS_2 gradually, with evolution of H_2S ; heated to redness with steam gives $\text{TiO}_2 \cdot x\text{H}_2\text{O}$, H_2S , and H ; nitric acid produces $\text{TiO}_2 \cdot x\text{H}_2\text{O}$, S , and NO ; aqua regia oxidises it to $\text{TiO}_2 \cdot x\text{H}_2\text{O}$ and H_2SO_4 ; not acted on by hydrochloric acid (H. Rose said that TiS_2 dissolved slowly in HClAq , giving off H_2S); insoluble in potassium sulphide solution; digestion with potash solution produces K titanate and KHSO_4 (Rose).

TITANIUM SESQUISULPHIDE Ti_2S_3 . Mol. w. unknown. Thorpe (C. J. 47, 491) obtained this compound by passing the vapours of moist H_2S and CS_2 over powdered TiO_2 heated to very bright redness in a porcelain tube; dry H_2S and CS_2 had no action on TiO_2 . T. describes Ti_2S_3 as a greenish-black powder; he did not obtain it quite free from TiS_2 , as by heating at a lower temperature than full redness in H_2S and CS_2 it is slowly changed to TiS_2 . O. v. d. Pfordten (A. 234, 257) obtained Ti_2S_3 by heating TiS_2 to full redness in dry H or N (S being set free); he describes it as a grey, metal-like solid; insoluble in NaOHAq ; soluble in HNO_3Aq or conc. H_2SO_4 forming green solutions.

TITANIUM MONOSULPHIDE TiS . Mol. w. unknown. Formed by very strongly heating TiS_2 in perfectly dry H quite free from O (T., l.c.; O. v. d. P., l.c.). A black powder (T., l.c.); forms dark-red crystals (O. v. d. P., l.c.). Slowly acted on by HNO_3Aq or aqua regia; insoluble in NaOHAq .

Titanium, sulphochloride of, v. TITANIUM THIOCHLORIDE, infra.

Titanium, thiochloride of. The pp. formed by passing pure dry H_2S into hot TiCl_3 is probably a thiochloride, according to O. v. d. Pfordten (A. 234, 257). M. M. P. M.

TITANIUM GROUP OF ELEMENTS. The four elements, *titanium, zirconium, cerium, and thorium* form, with carbon, the even-series family of Group IV. in the periodic classification of the elements. There is yet an element to be discovered between Ce and Th; this unknown element will come in series 10 of Group IV. The titanium family of elements is closely allied to the tin family—Ge, Sn, Pb—which, with Si, form the odd-series members of Group IV. Carbon is the first even-series member, and silicon the first odd-series member, of the group; these two elements are more like one another than they are like the rest of the group.

For the properties and relations of C and Si v. CARBON GROUP OF ELEMENTS, vol. i. p. 682; and for the tin family v. TIN GROUP OF ELEMENTS, this vol. p. 735.

The presence of an element, before unknown, in a Cornish mineral was recognised by Gregor in 1791, and by Klaproth a few years later; the element—called titanium by Klaproth—was isolated by Berzelius in 1824. Klaproth, in 1789, recognised the presence of a new earth in *zirconite* from Ceylon; the metal zirconium was isolated by Berzelius in 1824. In 1803 the presence of a new earth in a Swedish mineral was announced by Klaproth, who gave the name of cerium to the metal of the earth he had discovered; Mosander isolated the element in 1826. Berzelius discovered a new earth, in a Norwegian mineral, in 1828, and isolated the metal of the

earth, which he called thorium, in the same year.

None of the four elements Ti, Zr, Ce, or Th occurs native; the compounds of these elements are comparatively rare, especially those of Ca and Th.

The most frequently found compounds are the oxides MO_2 , generally in combination with SiO_2 and with alkaline earths. The metals are obtained by reducing their double fluorides by Al, K, or Na; also in some cases by reducing the chlorides by K or Na; Ce has also been isolated by electrolysis molten CeCl_3 . The table on the following page presents some of the physical and chemical properties of the elements.

General formulæ and characters of compounds.—Oxides.— MO_2 , probably for all (? Th_2O_3); MO_3 , for all; M_2O_3 , when $\text{M} = \text{Ti}$ or Ce; perhaps TiO . Hydrates of MO_2 exist.

Sulphides.— MS_2 , when $\text{M} = \text{Ti}$ or Th, ? Zr; M_2S_3 , when $\text{M} = \text{Ti}$ or Ce; TiS .

Haloid compounds.— MX_3 , when $\text{X} = \text{Br}$, Cl, F or I (only CeF_3 prepared); MX_2 , when $\text{M} = \text{Ti}$, and $\text{X} = \text{Cl}$, also when $\text{M} = \text{Ce}$ and $\text{X} = \text{Br}$, Cl, F or I; TiCl_4 . Salts.— MR_2 , $\text{R} = \text{NO}_2$, $\frac{1}{2}\text{SO}_4$, $\frac{1}{2}\text{PO}_4$, &c.; most are basic when $\text{M} = \text{Ti}$ or Zr, but when $\text{M} = \text{Ce}$ many are normal, and when $\text{M} = \text{Th}$ most are normal; several salts Ce_2R_3 are known, and a few Ti_2R_3 ; the Ce_2R_3 salts are more stable than the CeR_2 salts. Salts containing M in the acidic radicle.— M_2TiO_4 and others of general form $x\text{MO}_2 \cdot y\text{TiO}_2$; M_2ZrO_3 , M_2ZrO_4 , and others of general form $x\text{MO}_2 \cdot y\text{ZrO}_2$. No cerates or thorates isolated. Salts X_2MF_6 known when $\text{M} = \text{Ti}$, Zr, or Th; $3\text{CeF}_4 \cdot 3\text{KF}$ known. Acids.— H_2TiO_4 , $\text{H}_2\text{Ti}_2\text{O}_7$, H_2TiO_3 , H_2TiF_6 ; various hydrates $x\text{ZrO}_2 \cdot y\text{H}_2\text{O}$ act as feeble acids; H_2ThO_4 and $\text{H}_2\text{Th}_2\text{O}_7$ are perhaps feeble acids, but it is said that ThO_2 does not decompose alkali carbonates when fused therewith.

The oxides MO_2 are basic, and also feebly acidic when M is Ti or Zr; they interact with some acids to form corresponding salts, and, when $\text{M} = \text{Ti}$ or Zr, with alkalis to form salts wherein M forms part of the acidic radicle; no salts of oxyacids with Ce or Th in the negative radicles have yet been isolated. Several hydrates of MO_2 exist, they easily pass one into the other with small changes of temperature; some of these hydrates react as feeble acids towards strong bases, forming salts of the types X^1MO_2 , X^1MO_3 , and, generally, $x\text{X}^1\text{O}_2 \cdot y\text{MO}_2$; these salts are not referable to such definite forms as the stannates or silicates are, but they resemble these classes of salts fairly closely.

The salts which are derived from the oxides MO_2 , by the interactions of these oxides with acids, are of the form MX_2 , where $\text{X} = \text{NO}_2$, $\frac{1}{2}\text{SO}_4$, $\frac{1}{2}\text{PO}_4$, &c.; when $\text{M} = \text{Ti}$ most of the salts that are known are basic; when $\text{M} = \text{Zr}$, many are basic, but a fair number of normal salts is also known; when $\text{M} = \text{Ce}$ or Th, most of the salts that have been isolated are normal. Little is known of the oxides MO_3 ; as they are obtained by adding $\text{H}_2\text{O}_2\text{Aq}$ and an alkali to solutions of salts MX_3 , they are probably superoxides; the formula Th_2O_3 that is assigned to the oxide of Th formed in this way cannot be accepted as final. The oxides Ti_2O_3 and Ce_2O_3 are basic; the most definite and stable salts of

	TITANIUM.	ZIRCONIUM.	CEURIUM.	THORIUM.
<i>Atomic weights.</i>	48	90	189.9	232
	Molecular weights unknown. Mol. weights of one or more compounds of each element, except Ce, have been determined by Avogadro's law; spec. heats determined directly.			
<i>Melting-points.</i>	Has not been fused	c. 1200°	c. 800°	Has not been fused
<i>Spec. gravities (approx.)</i>	3.6	4.2	6.7	11.0
<i>Spec. heats.</i>	.13	.066	.0448	.0276
<i>Atomic weight.</i>	18.4	21.4	21.1	21.1
<i>Spec. gravities (approx.)</i>				
<i>Physical properties.</i>	Obtained only as a powder; black, lustrous, apparently amorphous. The powder has not been fused.	A black amorphous powder; resembling lampblack, but much heavier. Also obtained as a very lustrous, hard, brittle solid, resembling Sb. Said to melt above m.p. of Si.	Steel-grey, very lustrous metal; malleable, and ductile. Melts much more easily than any other member of the family.	Dark-grey, lustrous powder; also obtained in microscopic octahedral crystals. Has not been fused.
<i>Occurrence and Preparation.</i>	The four metals occur chiefly as silicates, Ti and Zr in moderate quantities and the others only in a few rare minerals. The metals are prepared by reducing the chlorides, or alkali salts of the form K_2 (or Na_2) MF_6 , by heating with K or Na; Ce also prepared by electrolysing molten $CeCl_4$.			
<i>Chemical properties.</i>	Burns brilliantly when heated in air, or in O, forming TiO_2 . Decomposes H_2O at 100°, giving off H. Combines readily with Cl, less readily with Br, and with I only when vapour of I is passed over heated Ti. Dissolves in warm dilute $HClAq$, H_2SO_4Aq , HNO_3Aq , or $HFAq$. Forms two classes of salts TiX_3 and TiX_4 , $X = NO_2$, $\frac{1}{2}SO_4$, &c.; very few TiX_3 salts isolated, and not many TiX_4 ; all salts easily decomposed. Salts derived from the acidic hydrates $\alpha TiO_2 \cdot yH_2O$ also known. The acids H_2TiF_6 and $H_2TiO_6F_2$, and salts derived therefrom, are known. TiO_2 , probably a superoxide, exists. Combines fairly readily with N, and with N and C. Atom of Ti is tetravalent in gaseous molecules $TiCl_4$ and TiI_4 .	Amorphous Zr burns brilliantly when heated in air, or O, forming ZrO_2 ; the crystalline metal is superficially oxidised at a white heat; it burns in O-H flame. Combines with Cl, probably also with Br and I; compounds ZrX_3 are formed by heating ZrO_2 and C in X. Combines directly with S. Dissolves slowly in hot H_2SO_4 , $HClAq$, HNO_3Aq ; rapidly in $HFAq$. Decomposes molten KOH ; crystalline Zr is said not to be oxidised by molten KNO_3 or $KClO_4$. Forms salts ZrX_3 , $X = NO_2$, $\frac{1}{2}SO_4$, &c.; most salts isolated are basic, $\alpha ZrO_2 \cdot yR$. Salts derived from acid H_2ZrF_6 are known. Also forms zirconates $yMO \cdot zZrO_2$, where Zr enters into negative radicle of salts. Oxide higher than ZrO_2 , probably ZrO_3 , (? superoxide) exists. ZrH_4 perhaps exists. Atom of Zr is tetravalent in gaseous molecule $ZrCl_4$.	Burns when heated in air, or O, to CeO_2 . Decomposes cold water, giving off H. Combines directly with Cl, Br, I vapour, S vapour, and P vapour. Dissolves easily in $HClAq$, HNO_3Aq , H_2SO_4Aq , or $HFAq$. Forms two classes of salts, Ce_2X_6 and CeX_4 , $X = NO_2$, $\frac{1}{2}SO_4$, &c.; salts Ce_2X_6 are more stable than CeX_4 , the latter are easily reduced to Ce_2X_6 . No cerates, where Ce forms part of negative radicle, have been isolated. Salts of form M_2CeF_6 not isolated. CeO_3 , probably a superoxide, seems to exist.	Burns, when heated in air or O below redness, to ThO_2 . Combines with Cl, Br, or I when heated; also with S vapour when heated therein. Easily dissolved by $HClAq$ or $HFAq$; slowly by hot H_2SO_4Aq ; HNO_3Aq has only a slight action. Forms salts ThX_3 , $X = NO_2$, $\frac{1}{2}SO_4$, &c.; fair number of basic salts known. Hydrates of ThO_2 , $ThO_2 \cdot 2H_2O$ and $4ThO_2 \cdot H_2O$, are probably weak acids, but thorates have not been isolated. Oxide higher than ThO_2 , probably Th_2O_3 , isolated (? superoxide). ThH_4 , perhaps exists. Atom of Th is tetravalent in gaseous molecule $ThCl_4$.

Ce are derived from this oxide. Several of the haloid compounds MX_3 have been gasified without decomposition, viz. $TiCl_4$, TiF_4 , $ZrCl_4$, and $ThCl_4$. The haloid compounds MX_3 form many double compounds with other halides; some of these are certainly best regarded as salts of hypothetical acids containing M and X in their acidic radicles; the salts of this class R_3MF_6 are characteristic of the elements of Group IV.; all the elements of the group, except C and Ce, give these salts R_3MF_6 . Ce is said to form K_2CeF_{11} ($= 2CeF_6 \cdot 3KF$), but further examination will most probably lead to the isolation of salts R_3CeF_6 . Ti and Ce form chlorides MX_3 , or more probably M_2X_6 from the analogy of C_2Cl_6 and Si_2Cl_6 ; Ce also forms Ce_2Br_6 , Ce_2F_6 , and Ce_2I_6 , indeed the only haloid compound of Ce belonging to the form MX_3 that has yet been isolated is CeF_3 . The sulphides have not been thoroughly examined; Ti is the only member of Group IV. which is known to form three sulphides corresponding with the oxides, TiS , Ti_2S_3 , and TiS_2 ; one sulphide of Zr is known, probably ZrS_2 ; ThS_2 is the only sulphide of Th that has been isolated; and the only known sulphide of Ce is Ce_2S_3 . So far as investigation has gone, the sulphides of Ti, Zr, Ce, and Th are basic.

A comparison of the titanium family with the tin family, which comprises the odd-series members of Group IV. (C and Si being omitted), shows that Ti, Zr, Ce, and Th are more metallic, on the whole, than Ge, Sn, and Pb. Th is certainly the most markedly positive element of Group IV., and Ti is at least not more negative than Ge; Zr is more metallic than Ge, and Ce more metallic than tin. The following formulæ show that, so far as composition goes, there is about an equal similarity between C and Si and the Ti elements, as between C and Si and the tin elements:

Oxides				Sulphides				Chlorides, &c.			
CO	? C_2O_3	CO ₂		CS	? C_2S_3	CS ₂			C ₂ Cl ₄	CCl ₄	
? SiO		SiO ₂		? SiS		SiS ₂		? SiCl ₂	Si ₂ Cl ₄	SiCl ₄	
? TiO	Ti ₂ O ₃	TiO ₂	TiO ₂	TiS	Ti ₂ S ₃	TiS ₂		TiCl ₂	Ti ₂ Cl ₄	TiCl ₄	
		ZrO ₂	ZrO ₂			ZrS ₂ (?)				ZrCl ₄	
	Ce ₂ O ₃	CeO ₂	CeO ₂		Ce ₂ S ₃				Ce ₂ Cl ₄	CeF ₄	
		ThO ₂	? ThO ₂			ThS ₂				ThCl ₄	
GeO		GeO ₂		GeS		GeS ₂		? GeCl ₂		GeCl ₄	
SnO ? Sn ₂ O ₃		SnO ₂		SnS ? ? Sn ₂ S ₃		SnS ₂		SnCl ₂		SnCl ₄	
PbO Pb ₂ O ₃		PbO ₂		PbS		? PbS ₂		PbCl ₂		PbCl ₄ (?)	

A comparison of the odd-series families of the different groups with the even-series families (omitting series 2 and 3) shows that, speaking broadly, the members of the even-series families are more metallic in their chemical properties than the members of the odd-series families, and that the general difference between even and odd families becomes more marked in the higher than in the lower groups (v. Table in vol. iii. p. 811). For instance, the even family of Group VI.—Cr, Mo, W, and U—is decidedly more metallic than the odd family of the same group—S, Se, and Te; but although the even family of Group II.—Ca, Sr and Ba—is more metallic than the odd family of the same group—Mg, Zn, Cd and Hg—there is not nearly so great a difference between these two families as

there is between the two families of Group VI. Considering that the titanium and the tin elements belong to even and odd series, respectively, of Group IV., which group comes midway in the general periodic scheme of classification, we should expect the titanium (even-series) family to be rather more metallic than the tin (odd-series) family, but at the same time we should expect these two families to be very like one another; this is exactly what a study of the two families shows to be the case.

In connection with this article v. TIN GROUP OF ELEMENTS, this vol. p. 735, and CARBON GROUP OF ELEMENTS, vol. i. p. 682).

ing *o*-toluic nitrile with hydroxylamine hydrochloride, alcohol, and Na_2CO_3 (Schubart, *B.* 22, 2438). Needles (from hot water), v. sol. alcohol and ether.

Ethyl ether $\text{C}_6\text{H}_4\text{C}(\text{NOEt})\text{NH}_2$. [140°]. Prisms, v. sol. alcohol.

Benzoyl derivative $\text{C}_6\text{H}_4\text{C}(\text{NOBz})\text{NH}_2$. [145°]. Needles, sol. alcohol. Conc. H_2SO_4 forms $\text{C}_6\text{H}_4\text{C} \begin{smallmatrix} \text{N} \cdot \text{O} \\ \diagup \quad \diagdown \end{smallmatrix} \text{C}_6\text{H}_5$ [80°].

o-Toluyll derivative $\text{C}_6\text{H}_3\text{C}(\text{NO.CO.C}_6\text{H}_5)\text{NH}_2$. [118°]. Converted at 180° into $\text{C}_6\text{H}_3\text{C} \begin{smallmatrix} \text{N} \cdot \text{O} \\ \diagup \quad \diagdown \end{smallmatrix} \text{C}_6\text{H}_4$ [59°] (Stieglitz, *B.* 22, 3156). Sodium diazobenzene sulphate forms $\text{C}_6\text{H}_3\text{C} \begin{smallmatrix} \text{N} \cdot \text{O} \\ \diagup \quad \diagdown \end{smallmatrix} \text{C}(\text{NH}_2)\text{C}_6\text{H}_5$ [110°].

p-Tolonyl-amidoxim $\text{C}_6\text{H}_4\text{N}_2\text{O}$ i.e. $\text{C}_6\text{H}_4\text{Me.C}(\text{NOH})\text{NH}_2$. *Toluamidoxim*. [146°]. Formed by combination of toluic nitrile with hydroxylamine (Schubart, *B.* 19, 1487). White plates, sol. alcohol, ether and hot water. Yields NaA , a hygroscopic mass, and $\text{HA} \cdot \text{HCl}$ [187°], crystallising in prisms.

Reactions.—1. *Benzene sulphonic chloride* forms $\text{C}_6\text{H}_3\text{C} \begin{smallmatrix} \text{N} \cdot \text{O} \\ \diagup \quad \diagdown \end{smallmatrix} \text{SO}_2\text{C}_6\text{H}_5$ [89°] (Pinner, *B.* 24, 4173).—2. *Aceto-acetic ether* gives rise to $\text{C}_6\text{H}_3\text{C} \begin{smallmatrix} \text{N} \cdot \text{O} \\ \diagup \quad \diagdown \end{smallmatrix} \text{C.CH}_2\text{Ac}$ [97°] (Schubart, *B.* 22, 2438).—3. *Acetic aldehyde* forms the compound $\text{C}_6\text{H}_3\text{C} \begin{smallmatrix} \text{N} \cdot \text{O} \\ \diagup \quad \diagdown \end{smallmatrix} \text{CHMe}$ [127.5°].—4. Hot HOAc forms $\text{C}_6\text{H}_3\text{C} \begin{smallmatrix} \text{N} \cdot \text{O} \\ \diagup \quad \diagdown \end{smallmatrix} \text{C.C}_6\text{H}_5$ [135°].—5. COCl_2 produces $\text{C}_6\text{H}_3\text{C} \begin{smallmatrix} \text{N} \cdot \text{O} \\ \diagup \quad \diagdown \end{smallmatrix} \text{CO}$ [220°].—6. ClCO_2Et yields $\text{C}_6\text{H}_3\text{C}(\text{NH}_2)\text{NO.CO}_2\text{Et}$ [180°].—7. *Phenyl cyanate* gives $\text{C}_6\text{H}_4\text{C}(\text{NOH})\text{NH.CO.NHPh}$ [155°].—8. *Phenyl thio-carbimide* reacts forming $\text{C}_6\text{H}_4\text{C}(\text{NOH})\text{NHCS.NHPh}$.—9. *Potassium cyanate* acting on the hydrochloride gives rise to $\text{C}_6\text{H}_3\text{C}(\text{NOH})\text{NH.CO.NH}_2$ [170°].—10. Ac_2O and NaOAc acting on the hydrochloride form $\text{NH}(\text{C}(\text{NH})\text{C}_6\text{H}_5)_2$ [153°] (Glock, *B.* 21, 2657).—11. *Succinic anhydride* forms the compound $\text{C}_6\text{H}_3\text{C} \begin{smallmatrix} \text{N} \cdot \text{O} \\ \diagup \quad \diagdown \end{smallmatrix} \text{C.CH}_2\text{CH}_2\text{CO}_2\text{H}$ [138.5°].—12.

Boiling Ac_2O forms $\text{C}_6\text{H}_3\text{C} \begin{smallmatrix} \text{N} \cdot \text{O} \\ \diagup \quad \diagdown \end{smallmatrix} \text{CMe}$ [80°].
13. CS_2 and alcohol form, on long boiling, $\text{C}_6\text{H}_3\text{C}(\text{NSH})\text{NH.CS.SHH}_2\text{N.C}(\text{NSH})\text{C}_6\text{H}_5$ (Crayen, *B.* 24, 390).—14. CS_2 and alcoholic potash yield $\text{C}_6\text{H}_3\text{C} \begin{smallmatrix} \text{N} \cdot \text{S} \\ \diagup \quad \diagdown \end{smallmatrix} \text{CS}$ [165°].

Methyl ether $\text{C}_6\text{H}_4\text{C}(\text{NOMe})\text{NH}_2$. [85°].

Ethyl ether EtA. [84°]. Needles. Converted by HBr and NaNO_2 into $\text{C}_6\text{H}_4\text{CBr.NOEt}$, an oil, decomposed at 155° (Schubart, *B.* 22, 2434), while hydrogen chloride and NaNO_2 form $\text{C}_6\text{H}_4\text{CCL.NOEt}$ (200°).

Benzoyl derivative $\text{C}_6\text{H}_3\text{C}(\text{NOBz})\text{NH}_2$. [178°]. Converted by heat into

$\text{C}_6\text{H}_3\text{C} \begin{smallmatrix} \text{N} \cdot \text{O} \\ \diagup \quad \diagdown \end{smallmatrix} \text{C}_6\text{H}_5$.

References.—NITRO- AND OXY-TOLUYLAMIDOXIM.

p-TOLONYL-IMIDO-ETHYL ETHER $\text{C}_6\text{H}_4\text{C}(\text{NH})\text{OEt}$. The hydrochloride $\text{B} \cdot \text{HCl}$ [161°] formed by the action of dry HCl on *p*-toluic nitrile dissolved in ether-alcohol forms

prisms, yielding $\text{B} \cdot \text{H}_2\text{PtCl}_4 \cdot 2\text{aq}$, converted at 200° into *p*-toluic amide, by NH_3 into *p*-tolonyl-amidide, by aniline into di-phenyl-tolonyl-amidine [168°], and by Ac_2O into the compound $\text{C}_6\text{H}_4\text{Me.C}(\text{NH})\text{OAc}$ [147°] (Glock, *B.* 21, 2650). The free base is liquid and changes on keeping into a polymeride [260°].

TOLONYL-PHENYLENE-DIAMINE

$\text{C}_6\text{H}_4 \begin{smallmatrix} \text{NH} \\ \diagup \quad \diagdown \end{smallmatrix} \text{C.C}_6\text{H}_5$. [268°]. Formed by reduction of tolyl-*o*-nitro-aniline and also from *p*-toluyll chloride and *o*-phenylene-diamine in benzene (Hübner a. Hanemann, *A.* 210, 328). Prisms, sl. sol. water, sol. alcohol.

TOLONYL-PHTHALAMIDONE $\text{C}_{10}\text{H}_8\text{N}_2\text{O}$ i.e.

$\text{C}_6\text{H}_4\text{Me} \begin{smallmatrix} \text{N} \\ \diagup \quad \diagdown \\ \text{C} \\ \diagup \quad \diagdown \end{smallmatrix} \text{C}_6\text{H}_4$. [188°]. "Got from

tolonyl-benzenyl-amidine *o*-carboxylic acid (Bistrzycki, *B.* 25, 1984).

TOLONYL-XYLENE-DIAMINE $\text{C}_{10}\text{H}_{10}\text{N}_2$

i.e. [1:4] $\text{C}_6\text{H}_4\text{Me} \begin{smallmatrix} \text{N} \\ \diagup \quad \diagdown \end{smallmatrix} \text{C}_6\text{H}_4\text{Me}_2$, $\left[\begin{smallmatrix} 5:1:3 \\ 6 \end{smallmatrix} \right]$ [217°]. Formed by reducing the *p*-toluyll derivative of nitro-xylidine (Brückner, *A.* 205, 125; Hübner, *A.* 210, 333). Long crystals (from dilute alcohol).— $\text{B} \cdot \text{HCl}$.— $\text{B} \cdot \text{HNO}_3$.— $\text{B} \cdot \text{H}_2\text{SO}_4$.

TOLIDINE v. DI-AMIDO-DITOLYL.

TOLL v. DI-TOLYL-DIKETONE.

TOLL-BENZOIN v. BENZOIN, Reaction 9.

TOLINDOLE v. METHYL-INDOLE.

TOLISATIN v. Methyl-ISATIN.

TOLU-ACET-ALDEHYDINE $\text{C}_{11}\text{H}_{14}\text{N}_2$ i.e.

$\text{C}_6\text{H}_4(\text{N.CHMe})_2$ or $\text{C}_6\text{H}_3 \begin{smallmatrix} \text{N} \\ \diagup \quad \diagdown \end{smallmatrix} \text{NEt} \begin{smallmatrix} \text{N} \\ \diagup \quad \diagdown \end{smallmatrix} \text{CMe}$ (?) [91° uncor.]. Formed together with a small quantity of ethenyl-tolylene-diamine, by mixing tolylene *o*-diamine (1 mol.) with aldehyde (2 mols.) in cold HOAc (Hinsberg, *B.* 20, 1588).

TOLU-AMIDOXIM v. TOLONYL-AMIDOXIM.

TOLU BALSAM. Obtained from incisions in the stem of *Myroxylum toluiferum* growing in Columbia, South America. It contains a terpene, toluene $\text{C}_{10}\text{H}_{16}$ (154°–170°), benzoic and cinnamic acids, benzyl cinnamate and two resins: $\text{C}_{10}\text{H}_{16}\text{O}_2$ [60°] v. sol. alcohol and ether and $\text{C}_{11}\text{H}_{20}\text{O}_2$ [above 100°], insol. alcohol and ether (Deville, *A.* 44, 304; Fittig, *A.* 97, 71; E. Kopp, *A.* 64, 372; Busse, *B.* 9, 830; Bailon, *Ph.* [8] 4, 385).

TOLUBENZYLAMINE v. METHYL-BENZYL-AMINE.

TOLUENE C_6H_6 i.e. $\text{C}_6\text{H}_5\text{CH}_3$. *Methyl-benzene*. *Retinaphiha*. *Phenyl-methane*. Mol. w. 92. V.D. 8.20 (calc. 8.29). (109°) (R. Schiff, *A.* 220, 91); (111°) (Wilbrand a. Bailestein, *A.* 128, 259; Tollens a. Fittig, *A.* 131, 304). S.G. $\frac{4}{4}$ 8656 (Brühl); $\frac{4}{4}$ 8566 (Gladstone, *C.* J. 59, 290); $\frac{4}{4}$ 8708 (S.). C.E. (13°–109°) 001242. S.V. 118 (S.). $\mu_D = 1.4893$ (G.). $\mu_B = 1.507$ (B.). $R_\infty = 50.06$. H.F.p. = 8520. H.F.v. = 5260 (Thomsen, *Th.*). H.C. 933,762 (Stohmann, *J. pr.* [2] 35, 41). Critical temperature 321° (Pawlewski, *B.* 16, 2634). Occurs in cold tar (Mansfield). Obtained by dry distillation from balsam of tolu (Deville, *A. Ch.* [8] 3, 168; Muspratt a. Hofmann, *A.* 54, 9), from dragon's blood (Glénard a. Boudault, *C. R.* 19, 505), from the resin of *Pinus maritima* (Pelletier a. Walter,

A. Ch. [2] 87, 278), and from wood (Völckel, *A.* 86, 334).

Formation.—1. By distilling vulpic acid with KOH (Möller a. Strecker, *A.* 113, 69).—2. By the action of sodium on a mixture of bromobenzene and MeI (Fittig a. Tollens, *A.* 131, 303).—3. By passing petroleum vapour over red-hot charcoal (Letny, *B.* 11, 1210).—4. By heating petroleum with AlCl_3 in presence of PbO and air (Friedel a. Crafts, *Z.* 1878, 1166).—5. By passing MeCl or CH_3Cl_2 into benzene containing AlCl_3 (Friedel a. Crafts, *A. Ch.* [6] 1, 460; 11, 264).—6. Together with CH_4 by heating benzene with MeI and I (Rayman a. Preis, *A.* 223, 317).—7. By distilling cresol with P_2S_5 (Geuther, *A.* 221, 58).—8. By distilling toluic acid with baryta (Noad, *A.* 63, 305).

Properties.—Oil, smelling like benzene.

Reactions.—1. When passed through a red-hot tube it yields benzene, styrene, naphthalene, diphenyl, anthracene, phenanthrene, and other products (Ferko, *B.* 20, 661; cf. Berthelot, *Bl.* 7, 218; Graebe, *B.* 7, 48).—2. Distillation over red-hot PbO gives benzene, di-phenyl-ethylene, diphenyl, phenanthrene, and anthracene (Lorenz, *B.* 7, 1097; Vincent, *C. R.* 100, 908).—3. By electrolysis of toluene to which alcohol and H_2SO_4 have been added benzoic aldehyde and phenose are formed (Rénard, *C. R.* 92, 965).—4.—When electric sparks are passed through toluene, acetylene and hydrogen are given off (Destrem, *Bl.* [2] 42, 267).—5. AlCl_3 at 200° in sealed tubes forms benzene, and *m*- and *p*-xylene (Friedel a. Crafts, *C. R.* 100, 692; Anschütz, *A.* 235, 178).—6. Oxygen passed through toluene containing AlCl_3 forms cresol (Friedel a. Crafts, *C. R.* 86, 884).—7. A mixture of toluene and ethylene passed through a red-hot tube yields benzene, styrene, and anthracene (Ferko).—8. CH_2Cl_2 and AlCl_3 yield di-tolyl-methane (280° – 290°), di-methyl-anthracene [232°], and *m*- and *p*-xylenes (Friedel a. Crafts, *Bl.* [2] 41, 322).—9. Bromine acts upon toluene in the dark as readily as in diffused daylight, with production of *o*- and *p*-bromo-toluene. The addition of iodine greatly hastens the reaction, but the same products are formed. In direct sunlight the substitution takes place entirely in the side-chain, with production of benzyl bromide. But if iodine (even 2 p.c.) is present the effect of the sunshine is entirely counteracted, and the substitution takes place wholly in the nucleus (Schramm, *B.* 18, 606; cf. Zakrzewski, *M.* 8, 304).—10. Chlorine, in presence of I, acting even on boiling toluene, forms chloro-toluene and benzyl chloride (Beilstein a. Geitner, *A.* 231, 170; cf. Aronheim, *B.* 8, 1401).—11. CrO_2Cl_2 added slowly to a solution of toluene in CS_2 ppts. $\text{C}_6\text{H}_5\text{CrO}_2\text{Cl}_2$, which slowly absorbs moisture, being converted into benzoic aldehyde (Étard, *A. Ch.* [5] 22, 223).—12. H_2SO_4 yields the *o*- and *p*-sulphonic acids, converted by potash-fusion into *o*- and *p*-cresol (Wurtz, *A. Ch.* [4] 26, 108).—13. Bz_2O_2 forms C_6H_4 (c. 260°) isomeric with the di-phenyl-ethylenes, and yielding benzoic acid on oxidation (Lippmann, *M.* 7, 521).—14. HNO_3 forms *o*- and *p*-nitro-toluene.—15. *Paraldehyde* and conc. H_2SO_4 form ditolylethane and $\text{C}_{12}\text{H}_{22}$ (350° – 360°) (O. Fischer, *B.* 7, 1194).

Compounds (C_6H_5), AlCl_3 . S.G. 2.108 (Gus-Vol. IV.

tavson, *B.* 11, 2151). Oil.—(C_6H_5), AlBr_3 . S.G. 2.137.

Dihydrate C_6H_{10} . (105° – 108°). Formed by heating toluene with PH_4I at 350° (Baeyer, *A.* 155, 271; *Z.* [2] 4, 445).

Tetrahydrate C_6H_{12} . (104°). S.G. 1.797. Occurs in the product of distillation of colophony (Rénard, *A. Ch.* [6] 1, 231). Oil, sol. alcohol and ether. Rapidly absorbs oxygen. In contact with water it forms crystalline $\text{C}_6\text{H}_{10}\text{O}_2$. H_2SO_4 forms two polymerides (230° – 235°), one only being oxidisable by air.

Hexahydrate C_6H_{14} . (97°). S.G. 1.7741. C.E. (0° – 20°)—0.0113. S.V. 142 (Lossen, *A.* 225, 109). H.C. 1,092,800 (Lougouine, *C. R.* 93, 275). Formed by heating toluene with conc. HIAq at 280° (Wreden, *A.* 187, 161; cf. Berthelot, *Bl.* [2] 7, 124; 26, 146). Occurs in oil of resin. Completely oxidised by a hot mixture of HNO_3 and H_2SO_4 .

TOLUENE ARSONIC ACID v. ARSENIC.

TOLUENE-AZIMIDO-TOLUENE v. AZIMIDO-COMPOUNDS.

TOLUENE-AZO- compounds v. AZO-COMPOUNDS AND DIAZO-COMPOUNDS.

TOLUENE-AZOXY- compounds v. AZOXY-COMPOUNDS.

TOLUENE CARBOXYLIC ACID v. TOLUIC ACID.

Toluene dicarboxylic acid $\text{C}_6\text{H}_4\text{O}_4$, i.e. $\text{C}_6\text{H}_4\text{Me}(\text{CO}_2\text{H})_2$ [4:2:1]. *Methyl-phthalic acid*. Mol. w. 180. [152°]. Formed from (*a*)-amido-*p*-toluic nitrile by Sandmeyer's reaction, the resulting nitrile being saponified (Niementowski, *M.* 12, 623). V. e. sol. water and alcohol. With *o*-amido-phenol it forms $\text{C}_6\text{H}_3\text{Me}(\text{CO})_2\text{N.C}_6\text{H}_4\text{OH}$ [205°], whence boiling aqueous sodium carbonate gives rise to $\text{C}_6\text{H}_3\text{Me}(\text{CO}_2\text{H})_2\text{CO.NH.C}_6\text{H}_4\text{OH}$ [200°].

Amide $\text{C}_6\text{H}_3\text{Me}(\text{CONH}_2)_2$. [188°]. Formed from the imide and NH_4Aq .

Anhydride. [92°]. Needles.

Imide $\text{C}_6\text{H}_3\text{Me.C}_2\text{O}_2\text{NH}$. [196°]. Got by fusing the anhydride with urea. Needles.

Nitrile $\text{C}_6\text{H}_3\text{Me}(\text{CN})_2$. [120°] (N.); [117°] (Glock, *B.* 21, 2663). Needles. Converted by alcohol and HCl into $\text{C}_6\text{H}_3\text{Cy.C}(\text{NH}_2\text{Cl})\text{OEt}$ [199°].

Toluene dicarboxylic acid

$\text{C}_6\text{H}_3\text{Me}(\text{CO}_2\text{H})_2$ [4:3:1]. (*β*)-*Xylydic acid*. *Methyl-isophthalic acid*. [320° – 330°]. Formed by oxidation of *m*-xylene carboxylic acid (Jacobsen, *B.* 14, 2112) and of $\text{C}_6\text{H}_3\text{Me}(\text{CH}_2\text{OH})_2$ (Hjelt a. Gadd, *B.* 19, 868). Formed also by fusing potassium toluene *m*-disulphonate or the salt $\text{C}_6\text{H}_3\text{Me}(\text{SO}_3\text{NH}_4)_2\text{CO}_2\text{K}$ with sodium formate (Hakansson, *B.* 5, 1088; Remsen a. Iles, *Am.* 1, 119). The same acid (?) is got by oxidation of $\text{C}_6\text{H}_3\text{Me.CO}_2\text{H}$ [1:4:2] by HNO_3 (S.G. 1.12) at 150° (Claus a. Wollner, *B.* 18, 1858). Small crystals, sl. sol. hot water. May be sublimed.— AgA'' : crystals, v. sol. hot water.

Toluene dicarboxylic acid

$\text{C}_6\text{H}_3\text{Me}(\text{CO}_2\text{H})_2$ [2:4:1]. *Methyl-terephthalic acid*. (*α*)-*Xylydic acid*. [α . 282°]. Formed by boiling pseudocumene with dilute HNO_3 (Fittig a. Laubinger, *A.* 151, 276). Got also by fusing

$C_6H_5Me(SO_3NH_2)CO_2K$ with sodium formate (Remsen a. Iles, *Am.* 1, 114). Needles (by sublimation). Sl. sol. Aq. Oxidised by $KMnO_4$ to trimellitic and isophthalic acids (Krinov, *B.* 10, 1494).— $*ZnA'$. S. 36 at 0° ; 735 at 100° ; 5 at 130° (Jacobsen, *B.* 10, 859).

Toluene dicarboxylic acid $C_6H_5Me(CO_2H)_2$. [310°-315°]. Formed by fusing potassium toluene (γ)-disulphonate with sodium formate (Senhofer, *A.* 164, 134). Minute needles, v. sl. sol. cold water, v. sol. alcohol and ether. May be sublimed.— BaA' 2aq.— Ag_2A'' : amorphous pp.

Toluene ω -o-dicarboxylic acid $CO_2H.CH_2.C_6H_4.CO_2H$. [2:1]. *Homophthalic acid* v. *o*-Carboxy-phenyl-acetic acid.

Nitrile v. *o*-CYANO-BENZYL CYANIDE.

Toluene ω -m-dicarboxylic acid $CO_2H.CH_2.C_6H_4.CO_2H$ [3:1]. Formed by oxidation of *m*-di-ethyl-benzene (Allen a. Underwood, *Bl.* [2] 40, 100). Needles (from alcohol). Sublimes without melting at 200° - 210° .— Ag_2A'' .

Toluene ω -p-dicarboxylic acid $CO_2H.CH_2.C_6H_4.CO_2H$. [285°-288°]. S. 1 at 50° . S. (alcohol) 14.3 at 80° . Formed by the action of dilute (25 p.c.) HCl on the amide (Mellinghoff, *B.* 22, 3215). V. sl. sol. ether and benzene.— Ag_2A'' : crystalline pp. The same (?) acid formed by oxidation of C_6H_4PrFr [1:4] yields BaA' $\frac{1}{2}$ aq (Paterno a. Spica, *B.* 10, 1746).

Amide $CO(NH_2).CH_2.C_6H_4.CO.NH_2$. [235°]. Formed from $CH_2Cy.C_6H_4.Cy$ and H_2SO_4 . Small hard nodules.

Amic acid $CO(NH_2).CH_2.C_6H_4.CO_2H$. [261°]. Formed from $CH_2Cy.C_6H_4.CO_2H$ and H_2SO_4 . Sl. sol. ether, hot water and alcohol.— AgA' : crystalline.

Iso-amic acid $CO_2H.CH_2.C_6H_4.CO.NH_2$. [229°]. Formed from *p*-cyano-phenyl-acetic acid. Crystalline, v. sol. alcohol and hot water.— AgA' . Crystalline.

Nitrile $CH_2Cy.C_6H_4.Cy$. *p*-Cyano-benzyl cyanide. [100°]. (above 360°). Formed from $CH_2Cl.C_6H_4.Cy$ and KCy (Mellinghoff, *B.* 22, 3209). Needles, v. sl. sol. hot water, sol. alcohol and ether.

Semi-nitrile $CH_2Cy.C_6H_4.CO_2H$. [201°]. Formed from ω -chloro-*p*-toluic acid by treatment with $KOHAq$ and alcoholic KCy (Mellinghoff, *B.* 22, 3213). Crystalline, v. sol. alcohol and ether.— AgA' .

Semi-nitrile $CO_2H.CH_2.C_6H_4.Cy$. [152°]. Formed from the nitrile and HCl at 105° . Prisms, v. sol. alcohol.— AgA' . Crystalline.

Nitrile-amide $CH_2Cy.C_6H_4.CO.NH_2$. [182°]. Formed from ω -chloro-*p*-toluic amide and KCy . Plates.

Amide - nitrile $CO(NH_2).CH_2.C_6H_4.Cy$. [196°-5°]. Formed from the nitrile and HCl at 70° . Crystalline, v. sol. alcohol.

Toluene tri-carboxylic acid $C_6H_3(CO_2H)_3$. Formed in small quantity by oxidation of *s*-tri-ethyl-benzene (Friedel a. Balsohn, *Bl.* [2] 34, 635). Needles. Sublimes before melting.— Ag_2A''' . Tables (from hot water).

TOLUENE o-PHOSPHINIC ACID $C_6H_5Me.P(OH)_2$. Obtained by decomposing its chloride with water (Michaelis a. Paneck, *A.* 212, 223). Oil. Monobasic acid.— CaA' 2aq.

Chloride $C_6H_5Me.PCl_2$. (244°). Formed

by the action of PCl_3 on mercury ditolyl [107°] and by warming toluene with $AlCl_3$ and PCl_3 . Liquid.

Toluene *p*-phosphinic acid $C_6H_5Me.P(OH)_2$. [105°]. Formed in like manner. Plates, v. sl. sol. water. Oxidised by HNO_3 to the phosphonic acid. Decomposed on heating into tolylphosphine and toluene phosphonic acid.— KA' .— NH_4A' .— BaA' 2aq.— PbA' 2.— CuA' 4aq.

Ether $C_6H_5Me.P(OEt)_2$. [280°]. Formed from the chloride and dry $NaOEt$.

Chloride $C_6H_5Me.PCl_2$. [25°]. (245°). Formed, together with the *o*-isomeride, from toluene, PCl_3 , and $AlCl_3$ (Michaelis a. Paneck, *A.* 212, 203). Formed also from $Hg(C_6H_5)_2$ [235°] and PCl_3 . Needles, v. sol. ether and benzene.

References.—NITRO- and OXY-TOLUENE PHOSPHINIC ACID.

TOLUENE PHOSPHINIC ANHYDRIDE v. PHOSPHINO-TOLUENE.

TOLUENE o-PHOSPHONIC ACID $C_6H_5Me.PO(OH)_2$. [141°]. Formed by the action of water on its chloride (Michaelis a. Paneck, *A.* 212, 231). Crystals, v. sol. water.— Ag_2A'' .

Chloride $C_6H_5Me.PCl_2$. This is formed from $C_6H_5.PCl_2$ and chlorine. Yellow solid.

Toluene *p*-phosphonic acid $C_6H_5Me.PO(OH)_2$. [189°]. Formed from $C_6H_5.PCl_2$ and cold water. Woolly needles. Oxidised by alkaline $KMnO_4$ to $CO_2H.C_6H_4.PO(OH)_2$. Bromine forms bromotoluene.— KH_2A'' : needles.— BaH_2A'' .— $AgHA''$.— Ag_2A'' .

Chloride $C_6H_5Me.PCl_2$. [42°]. Formed from $C_6H_5.PCl_2$ and chlorine. Yellow mass, converted by dry SO_2 into liquid $C_6H_5Me.POCl_2$ (285°).

Toluene ω -phosphonic acid $C_6H_5Me.PO(OH)_2$. [166°]. Formed, together with $(C_6H_5)_2PO(OH)$ [191°], from benzoic aldehyde and PH_3I (Litthauer, *B.* 22, 2145). Stellate groups of prisms (from $HOAc$).

Reference.—OXY-TOLUENE PHOSPHONIC ACID.

TOLUENE ω -SELINIC ACID $C_6H_5SeO_2$ i.e. $C_6H_5.CH_2SeO.OH$. [85°]. Formed by oxidising benzyl diselenide with HNO_3 (Jackson, *A.* 179, 8). Needles, sl. sol. cold water, v. sol. alcohol, nearly insol. ether.— AgA' : slender crystals (from hot water).

TOLUENE SULPHAMINE v. AMIDO-TOLUENE SULPHINIC ACID.

TOLUENE o-SULPHINIC ACID $C_6H_5SO_2$ i.e. $C_6H_5Me.SO.OH$. [80°]. Formed by boiling $C_6H_5.N_2H_5.SO_2.C_6H_5$ with baryta-water (Limpricht, *B.* 20, 1241). Long needles, v. sol. ether.— BaA' 3aq. Nodules, v. sol. water.

Toluene *p*-sulphinic acid $C_6H_5Me.SO_2H$. [85°]. Formed in like manner (Limpricht), and also from toluene *p*-sulphonic chloride and sodium-amalgam, zinc-dust, or Na_2SO_3 (Otto, *A.* 142, 92; 145, 19; *B.* 9, 1586; Blomstrand, *B.* 3, 965). Plates, v. sol. ether. Fuming HNO_3 forms crystals [190°]. The Na salt heated with $CH_3.CHCl_2$ and alcohol at 150° gives a small quantity of $CH_3.CHCl_2.SO_2.C_6H_5$ [48°] (Otto, *J. pr.* [2] 40, 519). The Na salt with $ClCO_2Et$ gives the ether (Otto, *B.* 26, 808).— BaA' . plates.— CaA' 4aq.— ZnA' 2aq.— AgA' .

Methyl ether. Formed from the Na salt and $ClCO_2Et$ in $MeOH$. Oil (Otto, *J. pr.* [2] 47, 166).

Ethyl ether EtA'. Oil. Oxidised by KMnO_4 in HOAc to toluene *p*-sulphonic ether (Otto a. Rossing, *B.* 19, 1226).

Toluene *exo*-sulphinic acid $\text{C}_6\text{H}_5\text{CH}_2\text{SO}_2\text{H}$. Prepared by reducing $\text{C}_6\text{H}_5\text{CH}_2\text{SO}_2\text{Cl}$ with sodium-amalgam (Otto a. Lüders, *B.* 13, 1288). Very unstable.—NaA': leaflets, sol. hot alcohol. Reference.—AMIDO-TOLUENE SULPHINIC ACID.

TOLUENE *o*-SULPHONIC ACID $\text{C}_6\text{H}_5\text{SO}_3$, *ie.* $\text{C}_6\text{H}_4\text{Me.SO}_3\text{H}$ [1:2].

Formation.—1. In small quantity together with the *p*-isomeride, by dissolving toluene in hot fuming H_2SO_4 (Engelhardt a. Latschinoff, *Z.* [2] 5, 617; Anna Wolkoff, *Z.* [2] 6, 321).—2. Together with the *m*- and *p*-isomerides by the action of ClSO_3H on toluene (Claesson a. Wallin, *B.* 12, 1848; Noyes, *Am.* 8, 176).—3. From *o*-toluidine by diazotisation followed by treatment with H_2SO_4 (Müller a. Wiesinger, *B.* 12, 1348).—4. By reducing *p*-bromo-toluene sulphonic acid with sodium-amalgam (Terry, *A.* 169, 27).—5. From (4,1,2)-nitro-toluene sulphonic acid by elimination of NO_2 (Jenssen, *A.* 172, 235).

Preparation.—By adding toluene (60 g.) to ClSO_3H (180 g.) in the cold, and pouring the product into water (Noyes).

Properties.—Thin leaflets (containing 2aq.), v. sol. water. Deliquescent.

Salts (C. a. W.; Hubner a. Post, *A.* 169, 1).—KA'aq.—NaA'aq.: tables, sol. water.—NH₄A': thin leaflets.—CaA'₂: leaflets, sl. sol. water.—BaA'₂aq. S. 4 at 12°.—BaA'₂4aq.—PbA'₂aq.—PbA'₂4aq.—MgA'₂7aq.—ZnA'₂7aq.—CuA'₂4aq.—CdA'₂2aq.—MnA'₂2aq.—AgA': sl. sol. water. *Chloride* $\text{C}_6\text{H}_5\text{SO}_3\text{Cl}$. Oil.

Amide $\text{C}_6\text{H}_5\text{SO}_2\text{NH}_2$. [154°]. S. 1 at 9°; S. (alcohol) 3·5 at 5°. Octahedra, sl. sol. water. Yields a benzoyl derivative [112°], which forms $\text{C}_6\text{H}_5\text{SO}_2\text{NKBz}$ 1½aq. and $(\text{C}_6\text{H}_5\text{SO}_2\text{NBz})_2\text{Ba}$ aq. (Wolkoff, *Z.* [2] 6, 57). Oxidised by KMnO_4 in acid solution to *o*-sulpho-benzoic acid and in neutral solution to $\text{C}_6\text{H}_4\text{SO}_3\text{NH}$ (Fahlberg a. List, *B.* 21, 242).

Anilide $\text{C}_6\text{H}_5\text{SO}_2\text{NHPh}$. [136°].

Toluide $\text{C}_6\text{H}_5\text{SO}_2\text{NHC}_6\text{H}_5$. [134°].

Toluene *m*-sulphonic acid $\text{C}_6\text{H}_4\text{Me.SO}_3\text{H}$ [1:3]. *Formation*.—1. By the action of H_2SO_4 on *m*-diazo-toluene salts (Müller a. Wiesinger, *B.* 12, 1349).—2. A product of the action of ClSO_3H on toluene (Claesson a. Wallin, *B.* 12, 1848).—3. From *o*-bromo-toluene *m*-sulphonic acid and sodium-amalgam (Müller, *A.* 169, 47).—4. By the diazo-reaction from *p*-toluidine sulphonic acid and from *o*-toluidine sulphonic acid (Pechmann, *A.* 173, 202; Pagel, *A.* 176, 297; Neville a. Winther, *C. J.* 37, 628; Kiason, *B.* 19, 2887).

Properties.—Thin deliquescent scales (containing aq.), v. sol. water.

Salts.—KA'aq.—NaA'aq.—NH₄A': scales, v. sol. water.—CaA'₂3aq.: needles, v. sol. water.—BaA'₂2aq.—BaA'₂aq. S. 22·75 at 12° (C. a. W.); 15·5 at 15° (Vallin, *B.* 19, 2952).—PbA'₂aq.—PbA'₂2aq.—PbA'₂3aq.—MgA'₂8aq.—ZnA'₂6aq.—ZnA'₂7aq.—CdA'₂5aq.—CdA'₂6aq.: crystals. MnA'₂7aq.—CuA'₂4aq.—AgA': v. sol. water. *Chloride* $\text{C}_6\text{H}_4\text{SO}_3\text{Cl}$. Oil.

Amide $\text{C}_6\text{H}_4\text{SO}_2\text{NH}_2$. [108°]. S. 4 at 9° (C. a. W.); 265 at 14° (V.). S. (alcohol) 18 at

5° (C. a. W.); 17·4 at 14° (V.). Monoclinic tables and octahedra (from alcohol). Melts at 91° according to Noyes. Oxidised by alkaline K_2FeCy_6 to $\text{CO}_2\text{H.C}_6\text{H}_4\text{SO}_3\text{NH}_2$ (Noyes a. Walker, *Am.* 8, 187).

Anilide $\text{C}_6\text{H}_4\text{SO}_2\text{NHPh}$. [72°].

m-Toluide $\text{C}_6\text{H}_4\text{SO}_2\text{NHC}_6\text{H}_5$. [103°].

Toluene *p*-sulphonic acid $\text{C}_6\text{H}_4\text{Me.SO}_3\text{H}$ [1:4]. The chief product of sulphonation of boiling toluene (Deville, *A. Ch.* [3] 8, 172; Fittig a. Tollens, *A.* 131, 310; Märcker, *A.* 136, 85; Engelhardt a. Latschinoff, *Z.* [2] 5, 617; Jaworsky, *Z.* 1865, 221; Otto a. Grüber, *A.* 142, 92; 145, 10; Chrustshoff, *B.* 7, 1167; Fahlberg, *B.* 12, 1048).—2. From toluene and ClSO_3H (Claesson a. Wallin, *B.* 12, 1848).—3. By the action of H_2SO_4 on *p*-diazo-toluene salts (M. a. W.).

Properties.—Thick leaflets or flat prisms (containing aq.). Deliquescent. Melts at 92° (Norton a. Otten, *Am.* 10, 140). Fusion with sodium formate yields *p*-toluic acid (Remsen, *B.* 8, 1412). Potash-fusion gives *p*-cresol. Hydrolysis by steam begins at 150° (Armstrong a. Miller, *C. J.* 45, 148).

Salts.—KA'aq. Trimetric crystals; *a:b:c* = 864:1:3·237.—NaA' 3aq.—NaA' 2aq.—NH₄A'.—CaA'₂4aq.—BaA'₂aq.—BaA'₂aq. S. 21 at 12°.—BaA'₂3aq. (Kelbe, *B.* 16, 621).—PbA'₂aq.—MgA'₂6aq.—ZnA'₂6aq.—CdA'₂6aq.—MnA'₂6aq.—CuA'₂6aq.—AgA': long plates, v. sol. water.

Methylamine salt [125°].— $\text{NMe}_2\text{H}_2\text{A}'$. [78°].— $\text{NMe}_2\text{HA}'$. [92°]. Aniline salt [223°].—*o*-Toluidine salt [180°] (N. a. O.).

Chloride $\text{C}_6\text{H}_4\text{SO}_3\text{Cl}$. [69°]. Triclinic crystals; *a:b:c* = 768:1:1·114; α = 97° 24'; β = 117° 6'; γ = 84° 28'. Acetoxim and NaOH form $\text{C}_6\text{H}_4\text{SO}_3\text{O.N.CMe}_2$ [89°] (Wege, *B.* 24, 3538). In ethereal solution it is reduced by sodium-amalgam to toluene sulphonic acid and the compound $\text{C}_6\text{H}_5\text{SO}_3$ [76°]. In presence of isoamyl ether ($\text{C}_5\text{H}_{11}\text{O}$) the compound $\text{C}_{12}\text{H}_{18}\text{S}_2\text{O}_4$ [36°] is formed (Otto, *A.* 143, 216).

Bromide $\text{C}_6\text{H}_4\text{SO}_3\text{Br}$. [96°].

Iodide $\text{C}_6\text{H}_4\text{SO}_3\text{I}$. [85°]. Formed by adding an alcoholic solution of I to aqueous $\text{C}_6\text{H}_4\text{SO}_3\text{Na}$ (Otto a. Tröger, *B.* 24, 479). Yellow crystalline powder, v. sol. ether, turning brown in air. Heated with water at 100° it forms $\text{C}_6\text{H}_4\text{S}_2\text{O}_6\text{C}_6\text{H}_5$. Reduced silver acts in like manner. ZnEt₂ forms zinc toluene sulphinate.

Methyl ether MeA'. [c. 80°].

Ethyl ether EtA'. [32°]. S.G. 22 1·174. Thick prisms (Kraft a. Roos, *B.* 25, 2259).

Phenyl ether $\text{C}_6\text{H}_4\text{SO}_3\text{OPh}$. [95°]. Formed by the action of NaOPh on the chloride dissolved in benzene (Otto, *B.* 19, 1832). Trimetric crystals; *a:b:c* = 289:1:476. Not affected by alcoholic NH_3 , even at 200°.

Amide $\text{C}_6\text{H}_4\text{SO}_2\text{NH}_2$. [186°]. S. 2 at 9°. S. (alcohol) 7·4 at 5°. Leaflets. Yields $\text{C}_6\text{H}_4\text{SO}_2\text{NHBz}$. BzCl forms $\text{C}_6\text{H}_4\text{SO}_2\text{NHBz}$ [147°–150°], which gives KA', CaA'₂aq, BaA'₂aq, AgA', and Ag₂NH₄, and is converted by POCl₃ into $\text{C}_6\text{H}_4\text{SO}_2\text{N.CCl.C}_6\text{H}_5$ [100°], whence ammonium carbonate solution forms $\text{C}_6\text{H}_4\text{N}_2\text{SO}_2$ [114°] (Wolkoff, *B.* 5, 140). Succinyl chloride forms crystalline $\text{C}_6\text{H}_4\text{SO}_2\text{N.C}_2\text{H}_3\text{O}_2$, converted by NH_4Aq into $\text{C}_6\text{H}_4\text{SO}_2\text{N}_2\text{H}_2(\text{C}_2\text{H}_3\text{O}_2)$ [180°] and

($C_6H_5SO_3$), N_2H_4 , ($C_6H_5O_2$), which crystallises from alcohol (Wolcott, Z. 1870, 580).

Methylamide $C_6H_5SO_3NHMe$. [75°]. Rectangular plates, sl. sol. hot water. Yields $C_6H_5SO_3NBzMe$ [58°].

Ethylamide $C_6H_5SO_3NHEt$. [58°].

Anilide $C_6H_5SO_3NHPh$. [103°]. $BzCl$ forms $C_6H_5SO_3NBzPh$ [149° cor.] (Remsen a. Palmer, Am. 8, 242).

Methylanilide $C_6H_5SO_3NMePh$ [95°]. Monoclinic crystals (Otto, J. pr. [2] 47, 371).

Ethyl-anilide [88°]. Prisms, insol. water.

p-Toluide $C_6H_4SO_3NHC_6H_5$. [118°].

Toluene exo-sulphonic acid $C_6H_4CH_2SO_3H$. Formed by boiling benzyl chloride with aqueous K_2SO_3 (Böhler, A. 154, 50; 221, 215; Mohr, A. 221, 216; Otto a. Lüders, B. 13, 1286). Formed also by oxidising benzyl disulphide with HNO_3 (Barbaglia, B. 5, 270, 688), and also, together with acetic acid, by heating benzyl methyl ketone with H_2SO_4 (Krekeler, B. 19, 2625). Very hygroscopic crystals. The K salt heated with KCy yields $C_6H_5CH_2CN$.

Salts.— NH_4A' .— KA' aq. Trimetric prisms. — BaA' 2aq. Plates, sl. sol. water. — CaA' 2aq. — PbA' (OH): crystals. — PbA' 2. — AgA' : crystalline.

Chloride $C_6H_4CH_2SO_3Cl$. [93°]. Decomposed by heat into SO_2 and benzyl chloride.

Amide $C_6H_4CH_2SO_3NH_2$. [102°] (O. a. L.) [105°] (Pechmann, B. 6, 534). Needles, sl. water and alcohol.

Toluene (α)-disulphonic acid $C_6H_3Me(SO_3H)_2$ [1:2:4]. Formed by sulphonation of toluene and of toluene o- or p-sulphonic acid (Hakansson, B. 5, 1084; Senhofer, A. 164, 129; Gnehm a. Forrer, B. 10, 542; Claesson a. Berg, B. 13, 1170; Klason, B. 20, 354). Formed also by heating toluene p-sulphonic chloride with H_2SO_4 (Fahlberg, B. 12, 1052; Am. 1, 170; 2, 182). Thick liquid. — $(NH_4)_2A''$ aq. — KA'' aq. — BaA'' aq. S. 75 at 17°. Insol. alcohol. — AgA'' 2aq. [52°].

Chloride $C_6H_3Me(SO_3Cl)_2$. [52°].

Amide $C_6H_3Me(SO_3NH_2)_2$. [186°].

Toluene (β)-disulphonic acid $C_6H_3Me(SO_3H)_2$ [1:2:5]. Formed by heating toluene o-sulphonic acid with fuming H_2SO_4 at 160° (H.), or toluene m-sulphonic acid with H_2SO_4 at 180° (Klason, B. 19, 2889; 20, 352). — KA'' aq. — BaA'' aq. S. 3.9 at 15° (K.).

Chloride $C_6H_3Me(SO_3Cl)_2$. [96°].

Amide $C_6H_3Me(SO_3NH_2)_2$. [224°].

Toluene disulphonic acid $C_6H_4Me(SO_3H)_2$ [1:2:8]. Formed by the action of sodium-amalgam on p-iodo-toluene disulphonic acid (Limpricht a. E. Richter, B. 18, 2179; A. 280, 326), and by heating toluene m-sulphonic acid with fuming H_2SO_4 at 180° (Klason). Slender needles, v. sol. water and alcohol. — KA'' aq. — BaA'' 3½aq. Prisms, v. sol. water.

Chloride $C_6H_4Me(SO_3Cl)_2$. [95°].

Amide $C_6H_4Me(SO_3NH_2)_2$. [214°].

Toluene o-disulphonic acid $C_6H_3Me(SO_3H)_2$ [1:2:6]. Formed by reduction of p-bromo-toluene disulphonic acid with sodium-amalgam (Kornatzki, A. 221, 199). — KA'' . — BaA'' 4aq. V. e. sol. water.

Chloride [86.5°]. Prisms (from ligroin).

Amide [above 260°]. Needles, v. sol. Ag.

Toluene disulphonic acid $C_6H_4Me(SO_3H)_2$ [1:3:4]. Formed from p-toluidine sulphonic acid by conversion into $C_6H_4Me(SH).SO_3H$ and

oxidation of the product (Klason, B. 20, 356). — KA'' aq. — BaA'' 2aq. S. 15. Prisms.

Chloride. [111°]. V. sol. $CHCl_3$.

Amide. [235°–239°]. V. sol. water.

Toluene-s-disulphonic acid

$C_6H_4Me(SO_3H)_2$ [1:3:5]. Formed from o-iodo- (or bromo-) toluene disulphonic acid or o-diazo-toluene disulphonic acid by long boiling with conc. HCl (Limpricht a. Hasse, B. 18, 2177; A. 230, 295). — KA'' 2½aq. — $(NH_4)_2A''$.

Chloride [132°]. Long prisms.

Amide [over 240°]. Small plates.

Toluene trisulphonic acid $C_6H_3Me(SO_3H)_3$. Formed by heating sodium toluene (α)-disulphonate with $ClSO_3H$ at 240° (Claesson, B. 14, 307). Slender needles (containing 6aq), v. sol. water. **Salts**. — KA''' 3½aq. — Pb_3A''' 8aq. — Ba_3A''' 14aq. Crystals, v. sol. water.

Chloride $C_6H_3Me(SO_3Cl)_3$. [153°].

Amide $C_6H_3Me(SO_3NH_2)_3$. [above 300°].

Minute crystals, nearly insol. water.

References.—AMIDO-, BROMO-, BROMO-AMIDO-, BROMO-NITRO-, CHLORO-, IODO-, IODO-AMIDO-, NITRO-AMIDO-, NITRO- and OXY- TOLUENE SULPHONIC ACID.

TOLUENE p-THIOSULPHONIC ACID

$C_6H_4Me.SO_2.SH$. Formed by heating a solution of a salt of toluene p-sulphinic acid with sulphur (Otto, B. 15, 129; 20, 2087) or by adding a mixture of Na_2S and $C_6H_4SO_3Na$ to an alcoholic solution of iodine (Otto a. Tröger, B. 24, 1182). A solution of Na salt gives a white pp. of cuprous salt on adding $CuSO_4$.

Reactions.—1. Iodine added to an alcoholic solution of the K salt forms the three compounds $(C_6H_4SO_2)_2S$ [134°], $(C_6H_4SO_2)_3S_2$ [109°], and $(C_6H_4SO_2)_3S_3$ [182°]. The compound $(C_6H_4SO_2)_2S$ is also formed by the action of I on a mixture of $C_6H_4SO_3Na$ and $C_6H_5SO_3Na$, and crystallises from benzene in monoclinic forms $a:b:c = 2.829:1.3:2.21$; $\beta = 60^\circ 7'$. The compound $(C_6H_4SO_2)_2S_2$ is split up by boiling $HOAc$ into $(C_6H_4SO_2)_2S$ and $(C_6H_4SO_2)_3S_3$ (Otto a. Tröger, B. 24, 1126).—2. $ClCO_2Et$ acting on the Na salt forms the ethyl and tolyl ethers and the compound $(C_6H_4SO_2)_3S_3$ [182°] (Otto a. Rossing, B. 24, 1148).

Salts.— NaA' 2aq. Trimetric tables. — KA' 2aq. — AgA' aq: small tables, sl. sol. water.

Ethyl ether $C_6H_4Me.SO_2.SET$. **Tolyl ethyl disulphoxide**. Got from NaA' and EtI . Oil.

Ethylene ether C_6H_4Me . [77°]. Needles. Decomposed by zinc-dust into the zinc salts of toluene sulphinic acid and ethylene mercaptan (Otto a. Heydecke, B. 25, 1478).

Tolyl ether $C_6H_4Me.SO_2.SC_6H_5$. **Tolyl disulphoxide**. [78°]. Formed by oxidation of p-tolyl mercaptan (Mäcker, A. 136, 83). Formed also from toluene p-sulphonic acid and water at 100° (Otto a. Tröger, B. 24, 480). Monoclinic prisms (from alcohol). Decomposed on saponification by alkalis into toluene p-sulphonic acid and di-tolyl disulphide [41°] (Otto a. Rössing, B. 19, 1240). Reduced by zinc and dilute H_2SO_4 to tolyl mercaptan. Bromine forms $(C_6H_4S_2O_2)_2Br_2$ (Otto a. Grüber, A. 149, 105). Alcoholic H_2S forms, on warming, toluene p-sulphinic acid, di-tolyl disulphide, and tolyl tetrasulphide.

Reference.—AMIDO-TOLUENE THIOSULPHONIC ACID.

TOLUENYL- v. TOLENYL-.

o-TOLUIC ACID $C_6H_4Me.CO_2H$ [1:2]. Mol. w. 136. [104°]. H.C.v. 928,800. H.C.p. 929,400. H.F. 98,600 (Stohmann, *J. pr.* [2] 40, 133).

Formation.—1. By oxidation of *o*-xylene with dilute HNO_3 (Bieber a. Fittig, *Z.* [2] 6, 496; *A.* 156, 242).—2. From toluene *o*-sulphonic acid *vid* $C_6H_4.CN$ (Ramsay a. Fittig, *Z.* [2] 7, 584; *A.* 168, 246).—3. By the action of sodium-amalgam on a mixture of $ClCO_2Et$ and *o*-iodotoluene and saponification of the resulting $C_6H_4.CO_2Et$ (Kekulé, *B.* 7, 1007).—4. By boiling phthalide (3 mols.) with $HIAq$ (127°) and yellow P (2 at.), the yield being 97 p.c. (Hessert, *B.* 11, 238; Racine, *A.* 239, 72).—5. From *o*-toluidine *vid* the nitrile (Cahn, *A.* 240, 280).

Properties.—Plates (containing 2aq), volatile with steam, sl. sol. cold water. Oxidised by alkaline $KMnO_4$ to phthalic acid (Weith, *B.* 7, 1057). Bromine-vapour above 100° forms phthalide; in the cold Br forms bromo-toluic acid $C_6H_3MeBr.CO_2H$ [167°].

Salts.— NaA' 2aq. [228°]. Efflorescent plates.— CaA'_2 2aq.— BaA'_2 2aq.

Ethyl ether EtA' . (220°).

Amido-ethyl ether

$C_6H_4.CO.O.CH_2.CH_2.NH_2$. Formed from *o*-tolyl-oxazoline and $HClAq$. Oil. Yields $B'HB$ [156°], $B'C_6H_3N_2O_2$ [188°].

Amido-propyl ether

$C_6H_4.CO.O.CHMe.CH_2.NH_2$. Formed by evaporating tolyl-methyl-oxazoline with $HClAq$. Yields $B'HB$ [140°], $B'C_6H_3N_2O_2$ [192°], and a platinum-chloride [214°].

Benzyl ether C_6H_4A' . (315°). S.G. $\frac{17}{11}$ 1.12. Oil (Hodgkinson, *C. J. Proc.* No. 103, p. 167).

Chloride $C_6H_4.OCl$. (211° at 733 mm.).

Anhydride $(C_6H_4.CO)_2O$. [c. 38°]. (above 325°). Formed from the Na salt (6 mols.) and $POCl_3$ (1 mol.). Insol. water, sol. ether and benzene.

Amide $C_6H_4.CONH_2$. [140°] (Hutchinson, *B.* 24, 174; *C. J.* 67, 957; cf. Weith, *B.* 6, 420). On reduction in acid solution it yields *o*-tolyl alcohol and a small quantity of the dihydride $C_6H_6.CO.NH_2$ [156°], which on boiling with water yields an acid [68°]. The dihydride is also formed by reducing the amide in alkaline solution.

Anilide $C_6H_4.CO.NHPh$. [125°]. Formed from *anti*-phenyl-*o*-tolyl ketoxim and PCl_5 followed by water (Smith, *B.* 24, 4047).

Xylide $C_6H_4.CO.NHC_6H_4Me$. [1:2:4]. [165°]. Formed by heating *o*-tolyl xylol ketone with hydroxylamine at 120° (Smith).

Bromo-ethylamide

$C_6H_4.CO.NH.CH_2.CH_2Br$. [71°] (Salomon, *B.* 26, 1822).

Chloro-ethylamide

$C_6H_4.CO.NH.CH_2.CH_2Cl$. [73°]. White needles.

Bromo-propyl-amide

$C_6H_4.CO.NH.CH_2.CH_2Br.CH_3$. [86°]. Needles (from benzene-ligroin) (Salomon, *B.* 26, 1323).

Chloro-propyl-amide

$C_6H_4.CO.NH.CH_2.CH_2MeCl$. [84°]. Formed by evaporating *o*-tolyl-methyl-oxazoline with excess of $HClAq$. Needles (from ligroin).

o-Nitro-benzyl-amide

$C_6H_4.CO.NH.CH_2.C_6H_4.NO_2$. [135°]. Needles (from alcohol). May be reduced to the *o*-amido-

benzyl-amide [116°], which yields $B'HCl$ [214°] (Wolff, *B.* 25, 3034).

Imide $(C_6H_4.CO)_2NH$. [148°].

Nitrile $C_6H_4.CN$. (204° cor.). V.D. 4.03 (obs.). H.F. —84,800 (Berthelot a. Petit, *A. Ch.* [6] 17, 123). Formed by heating KCy with potassium toluene *o*-sulphonate or with tri-*o*-tolyl phosphate (Heim, *B.* 16, 1776), by heating *o*-tolyl thiocarbimide with finely-divided copper (Weith, *B.* 6, 419), by boiling *o*-tolyl carbamine (Weith, *B.* 7, 722), by heating *o*-iodo-toluene with $AgCy$ at 350° (Merz a. Weith, *B.* 10, 751), by boiling the formyl derivative of *o*-toluidine with zinc-dust (the yield being 18 p.c.) (Gasiorowski a. Merz, *B.* 17, 74; 18, 1004), and by Sandmeyer's reaction from *o*-toluidine (Cahn, *B.* 19, 756). Liquid. H_2SO_4 at 60° to 70° forms $C_6H_4.C(NH).NH.CO.C_6H_4$ [108°], which is converted, by warming its acid solution, into the imide $(C_6H_4.CO)_2NH$ (Krafft a. Kerstens, *B.* 25, 455). Conc. $HIAq$ forms $C_6H_4.CL_2.NH_2$ [98°] (Biltz, *B.* 25, 2540).

Hexahydride v. METHYL-HEXAMETHYLENE CARBOXYLIC ACID.

m-Toluic acid $C_6H_4Me.CO_2H$ [1:3]. [110°] (Jacobsen, *B.* 14, 2347; Bornemann, *B.* 20, 1382). (263°). H.C.v. 928,500. H.C.p. 929,100. H.F. 98,900 (Stohmann, *J. pr.* [2] 40, 184). S. 0.9 at 15°; 1.66 at 100°.

Formation.—1. By oxidising bromo-xylene and reducing the resulting bromo-toluic acid with sodium-amalgam (Ahrens, *Z.* [2] 5, 106; Richter, *B.* 5, 424; Böttinger a. Ramsay, *A.* 168, 255).—2. By distilling vitic acid with lime (Fittig, *B.* 5, 268).—3. By oxidation of *m*-xylene with dilute HNO_3 (Tavildaroff, *B.* 4, 410; Brückner, *B.* 9, 406; Reuter, *B.* 17, 2028).—4. By saponifying the nitrile.

Preparation.—1. By boiling ω -chloro-xylene with HNO_3 (1 vol. of S.G. 1.4) and water (3 vols.) (Senff, *A.* 220, 247).—2. By sulphonating crude xylene, then preparing $C_6H_4Me_2.SO_2NH_2$, oxidising by $KMnO_4$, heating the resulting $C_6H_4Me(SO_2NH_2).CO_2H$ with HCl at 230°, and distilling with steam (Jacobsen, *B.* 14, 2347).

Properties.—Long needles, volatile with steam, v. sol. alcohol and ether. Oxidised by chromic acid mixture to isophthalic acid.

Salts.— CaA'_2 3aq. S. 3.17 at 15°; 8.2 at 100°.— BaA'_2 2aq: trimetric plates or tables.— AgA' .

Ethyl ether EtA' . (226°).

Chloride (218° at 724 mm.) (Ador a. Rilliet, *B.* 12, 2300).

Nitrile $C_6H_4.CN$. (209°). Formed by heating *m*-tolyl thiocarbimide with Cu (Weith a. Landolt, *B.* 8, 720), and in other ways (Buchka a. Schachtebeck, *B.* 22, 841).

p-Toluic acid $C_6H_4Me.CO_2H$ [1:4]. [179°]. (275° cor.) (Fischli, *B.* 12, 615). H.C.v. 926,800. H.C.p. 927,400. H.F. 100,600 (Stohmann, *J. pr.* [2] 40, 184).

Formation.—1. By the action of dilute HNO_3 on cymene (Noad, *P. M.* [3] 32, 19; *A.* 63, 289) on *p*-xylene (Beilstein, *A.* 187, 302; Brückner, *A.* 205, 113), and on terpenes (Hirzel, *Z.* 1866, 205).—2. By saponification of the nitrile.—3. By heating *p*-bromo-toluene with $ClCO_2Et$ and sodium-amalgam and saponifying the product (Wurtz, *C. R.* 68, 1298).—4. From *p*-bromo-toluene, CO_2 , and sodium (Kekulé, *A.*

187, 184).—5. By the action of POCl_3 (40 g.) on a mixture of toluene (40 g.), HOAc (80 g.) and ZnCl_2 (80 g.) at 110° (Frey, *J. pr.* [2] 43, 116).—6. By reducing bromo-*p*-toluic acid with sodium-amalgam (Remsen a. Morse, *Am.* 1, 138).—7. From the chloride which is formed by the action of COCl_2 on toluene in presence of AlCl_3 (Ador a. Crafts, *B.* 10, 2176).—8. From the amide which is formed by the action of AlCl_3 on a mixture of toluene, CS_2 , and NH_2COCl (Gattermann a. Schmidt, *B.* 20, 859).—9. By fusing $\text{C}_6\text{H}_5\text{CO}_2\text{C}_6\text{H}_4\text{CO}_2\text{H}$ with potash (Friedel a. Crafts, *Bl.* [2] 35, 508), and also by passing gaseous cyanic acid and HCl into toluene at 100° containing AlCl_3 (Gattermann a. Rossolymov, *B.* 23, 1195).

Properties.—Needles, v. sol. hot water, v. e. sol. alcohol and ether. Volatile with steam. Oxidised by CrO_3 or KMnO_4 to terephthalic acid. Yields a di-nitro-derivative [158°].

Salts.— KA' .— BaA'_2 , 2aq. needles (Buchka a. Irish, *B.* 20, 1764).— CaA'_2 , 3aq.— MgA'_2 , 3aq.— CuA'_2 .— AgA' .

Methyl ether MeA' . [32°]. (217°).

Ethyl ether EtA' . (228°). Oil.

Amido-ethyl ether $\text{C}_6\text{H}_5\text{CO}_2\text{C}_2\text{H}_5\text{NH}_2$. Yields $\text{B}'\text{HBr}$ [167°] and $\text{B}'\text{C}_6\text{H}_5\text{N}_3\text{O}$ [180°].

***p*-Amido-propyl ether**

$\text{C}_6\text{H}_5\text{CO}_2\text{C}_3\text{H}_7\text{NH}_2$. The hydrobromide $\text{B}'\text{HBr}$ is formed by evaporating a solution of the bromo-propyl-amide. It yields $\text{B}'\text{C}_6\text{H}_5\text{N}_3\text{O}$ [186°] and $\text{B}'\text{H}_2\text{PtCl}_6$.

Phenyl ether PhA' . [72°].

Chloride (225° at 720 mm.).

Amide $\text{C}_6\text{H}_5\text{CO.NH}_2$. [159°]. Formed by heating the NH_2 salt in sealed tubes at 230° (Hallemann, *R. T. C.* 6, 79).

Methylamide $\text{C}_6\text{H}_5\text{CO.NHMe}$. [143°]. Formed by the action of NHMe.COCl on toluene in presence of AlCl_3 (Gattermann a. Schmidt, *B.* 20, 120; *A.* 244, 51). Tables.

Ethylamide $\text{C}_6\text{H}_5\text{CO.NHEt}$. [96°].

Bromo-ethyl-amide

$\text{C}_6\text{H}_5\text{CO.NH.CH}_2\text{CH}_2\text{Br}$. [129°] (Salomon, *B.* 26, 1325). Formed from *p*-toluic chloride and bromo-ethylamine. Plates. Converted by boiling water into the amido-ethyl ether.

Chloro-ethyl-amide

$\text{C}_6\text{H}_5\text{CO.NH.CH}_2\text{CH}_2\text{Cl}$. [122°]. Needles (from ligroin).

Bromo-propyl-amide

$\text{C}_6\text{H}_5\text{CO.NH.CH}_2\text{CH}_2\text{CH}_2\text{Br}$. Melts at 74° , becomes solid, and melts again at 158° (*B.* 26, 1326).

Chloro-propyl-amide

$\text{C}_6\text{H}_5\text{CO.NH.CH}_2\text{CH}_2\text{CH}_2\text{Cl}$. [78°].

Anilide $\text{C}_6\text{H}_5\text{CO.NHPh}$. [145°]. Formed from toluene, phenylcyanate, and AlCl_3 (Leuckart, *J. pr.* [2] 41, 306).

***o*-Nitro-anilide**. [110°]. Yellow prisms.

***p*-Toluide** $\text{C}_6\text{H}_4\text{CO.NHOC}_6\text{H}_5$. [160°]. Formed by the action of sodium-amalgam and HOAc at 60° on an alcoholic solution of di-*p*-tolyl ketoxim (Goldschmidt a. Stöcker, *B.* 23, 2747; 24, 2799). Needles.

Nitro-toluide $\text{C}_6\text{H}_4\text{CO.NHOC}_6\text{H}_4\text{Me}(\text{NO}_2)$ [$4:1:3$]. [166°].

Diphenylamide $\text{O}_6\text{H}_4\text{CO.NPh}_2$. [155°]. Prisms (from alcohol) (Lellmann a. Bonhöffer, *B.* 20, 2118).

Xylide $\text{C}_6\text{H}_4\text{CO.NHOC}_6\text{H}_4\text{Me}_2$. [139°]. Yields $\text{C}_6\text{H}_4\text{CO.NH.C}_6\text{H}_4\text{Me}_2(\text{NO}_2)$ [187°].

Phenyl-methyl-amide $\text{C}_6\text{H}_5\text{CO.NPhMe}$. [70°] (Lellmann a. Benz, *B.* 24, 2114).

***o*-Nitro-benzyl-amide**

$\text{C}_6\text{H}_4\text{CO.NH.CH}_2\text{C}_6\text{H}_4\text{NO}_2$. [142°] (Wolff, *B.* 25, 3036).

Nitrile $\text{C}_6\text{H}_4\text{Me.CN}$. [$28\text{--}5^\circ$]. (218°).

Formed by distilling potassium toluene *p*-sulphonate with KC_6H_5 (Merz, *Z.* [2] 4, 33), by heating $\text{C}_6\text{H}_4\text{N.CS}$ with Cu (Weith, *B.* 6, 421), by heating tri-*p*-tolyl phosphate with KC_6H_5 (Heim, *B.* 16, 1775), and by passing $\text{C}_6\text{H}_5\text{NH.CHO}$ over heated zinc-dust (G. a. M.). Obtained also from *p*-toluidine by Sandmeyer's reaction (Glock, *B.* 21, 2650). Sodium added to its boiling alcoholic solution forms a small quantity of ω -amido-*p*-xylene, the greater part being saponified (Bamberger a. Lodter, *B.* 20, 1710). H_2SO_4 gives $\text{C}_6\text{H}_4\text{C}(\text{NH}).\text{NH.CO.C}_6\text{H}_4$ [145°]. Easily converted into the imide ($\text{C}_6\text{H}_4\text{CO})\text{NH}$ [155°] (Krafft a. Karstens, *B.* 25, 454). Conc. HIAc forms $\text{C}_6\text{H}_4\text{Cl}_2\text{NH}_2$ [$115\text{--}120^\circ$], decomposed by fusion (Biltz, *B.* 25, 2539).

Tetrahydride $\text{C}_6\text{H}_4\text{O}_2$. (252°). Formed

by reduction of $\text{CH}_2\text{C}(\text{CH}_2\text{CH})\text{CH}(\text{CH}_2\text{CH})\text{C}(\text{CO}_2\text{H})$ with sodium-amalgam (Einhorn a. Willstätter, *B.* 26, 2009). Needles, melting below 0° . Yields CaA'_2 , 4aq, CuA'_2 , 2aq, MeA' . ($210\text{--}220^\circ$), and an amide [158°]. Boiling NaOHAq converts the acid into a solid isomeride [47°] ($254\text{--}260^\circ$) which yields CaA'_2 , 4aq and an amide [135°]. **Hexahydride** (Serebojakoff, *B.* 25, 3355).

References.—AMIDO-, BROMO-, BROMO-NITRO-, CHLORO-, NITRO-, NITRO-AMIDO-, OXY-, OXY-AMIDO-, and SULPHO-TOLUIC ACID.

***o*-Toluic acid is PHENYL-ACETIC ACID.**

***o*-TOLUIC ALDEHYDE** $\text{C}_6\text{H}_4\text{Me.CHO}$ [$1:2$].

***o*-Toluylic aldehyde**. (200°). Prepared by boiling ω -chloro-*o*-xylene with lead nitrate solution (Lauth a. Grimaux, *Bl.* [2] 7, 233; Rayman, *Bl.* [2] 27, 498). Prepared also from *o*-xylene by the successive action of CrO_2Cl_2 and water (Bornemann, *B.* 17, 1467), and by oxidising $\text{C}_6\text{H}_4\text{Me.CH}_2\text{OH}$ with chromic acid mixture (Kröber, *B.* 23, 1029). Oil, smelling like bitter almonds. Yields a crystalline compound with NaHSO_4 . Reduced by sodium-amalgam to *o*-tolyl-carbinol.

Oxim $\text{C}_6\text{H}_4\text{Me.CH:NOH}$. [49°]. Is an anti-oxim. White crystals (from ether), v. sol. alcohol. Yields a crystalline hydrochloride. Ac_2O yields an acetyl derivative [56°]. AcCl acts in like manner. The acetyl derivative is decomposed by alkalis with regeneration of the oxim, no nitrile being formed (Dollfus, *B.* 25, 1921). The oxim is converted in ethereal solution by PCl_5 into the nitrile (204°).

***m*-Toluiic aldehyde** $\text{C}_6\text{H}_4\text{Me.CHO}$ [$1:3$]. (199°). S.G. d 1.037. Formed by boiling ω -chloro-*m*-xylene or ω -bromo-*m*-xylene with lead nitrate solution (Gundelach, *Bl.* [2] 26, 44; Müller, *B.* 20, 1213), and also by the action of water on $\text{C}_6\text{H}_4\text{CrO}_2\text{Cl}_2$ obtained from *m*-xylene (Étard, *B.* 14, 848; Bornemann, *B.* 17, 1464). Oil, smelling like almonds. Combines with NaHSO_4 . Aniline forms $\text{C}_6\text{H}_4\text{CH.NPh}$. (314°).

Phenyl-hydrazide $\text{C}_6\text{H}_4\text{Me.CH:N}_2\text{HPh}$. [91°]. (*B.*); [88°] (Rudolph, *A.* 248, 100). Prisms (from ligroin), v. sol. ether.

p-Toluic aldehyde $C_6H_4Me.CHO$ [1:4]. (205°). Formed by distilling calcium *p*-toluate with calcium formate (Cannizzaro, *A.* 124, 254). Formed also by the action of water on the product of combination of *p*-xylene with $CrO_3.Cl_2$ (Bornemann). Oil, with peppery smell. Oxidised by air to toluic acid. Alcoholic potash forms potassium toluate and tolyl-carbinol.

Reference.—NITRO- and OXY-TOLUIC ALDEHYDE.

TOLUIC CHLORIDE *v.* Chloride of TOLUIC ACID.

TOLUIDES. Compounds derived from toluidine by displacement of H in NH_2 by an acid radicle.

o-TOLUIDINE $C_6H_4Me.NH_2$ [1:2]. Mol. w. 107. (198°). S.G. d_4^{20} 9986 (Brühl, *A.* 200, 189). H.C.p. 964,700. H.C.v. 963,750. H.F. 3,800 (Petit, *C. R.* 107, 266). μ_s 1.5895. R_∞ 57.56. S.V. 126.6. Formed from *o*-cresol, $ZnBr_2$, NH_3 , and NH_4Cl at 335° (Merz a. Müller, *B.* 20, 547). Prepared by reduction of *o*-nitro-toluene. May be separated from *p*-toluidine by means of the acidoxalates (Bindschedler, *B.* 6, 448; Ihle, *J. pr.* [2] 14, 449; Miniati, Booth a. Cohen, *S. C. I.* 6, 418), by freezing (Rosenstiehl, *Bl.* [2] 17, 7), by means of the nitrates (Schad, *B.* 6, 1861), hydrochlorides, sulphates, or phosphates (Lewy, *Fr.* 23, 269; *B.* 19, 1717, 2728; *cf.* Wülfing, *B.* 19, 2132). *o*-Toluidine can be prepared from $C_6MeHBr(NH_2)(NO_2)H$ *vid* $C_6MeHBrI(NO_2)H$, $C_6MeHBrI(NH_2)H$, $C_6MeHBrIBrH$, followed by $C_6Me(NO_2)BrIBrH$, and $C_6Me(NH_2)BrIBrH$. It can also be got from $C_6Me(NH_2)BrIBrH$ *vid* $C_6MeIBrIBrH$, followed by $C_6MeIBrIBr(NO_2)$ and $C_6MeIBrIBr(NH_2)$ thus proving that the toluidine $C_6H_4Me(NH_2)$ [1:2] is identical with $C_6H_4Me(NH_2)$ [1:6] (Wroblewsky, *A.* 192, 213).

Properties.—Oil. A solution in $H_2SO_4.H_2O$ is coloured orange by HNO_3 and blue by CrO_3 , the solution in the latter case becoming reddish-violet on dilution. Forms a crystalline compound with liquid CO_2 at 8° (Bitte, *C. R.* 105, 614). With PbO_2 and aqueous acetic acid gives a green colour, while PbO_2 and alcoholic acetic acid gives a reddish-violet colour (Lauth, *C. R.* 111, 975). Unlike *p*-toluidine, it forms a crystalline compound with alloxan (Pellizzari, *C. C.* 1887, 1288, 1896). If an ethereal solution of *o*-toluidine is shaken with very dilute bleaching-powder solution the aqueous layer becomes yellow or brown, and the ethereal layer, if decanted and shaken with dilute H_2SO_4 , colours this reddish-violet. A solution of *p*-tolylene diamine hydrochloride mixed with a little *o*-toluidine gives a green colour on addition of $FeCl_3$ or $K_2Cr_2O_7$ (Nietzki, *B.* 10, 1157).

Reactions.—1. $POCl_3$ forms $PO(NHC_6H_4)_2$ [225°] (Michaelis a. Rudert, *B.* 26, 565), *v. sol.* water, whence Br forms $PO(NHC_6H_4BrMe)_2$ [253°]. Another product of the action of $POCl_3$ on *o*-toluidine is $POCl(NHC_6H_4Me)_2$, whence water forms $HO.PO(NHC_6H_4)_2$ [95°]. $PSCl_2$ forms $PS(NHC_6H_4)_2$ [135°].—2. $SiCl_4$ reacts forming $SiCl_2(NHC_6H_4)_2$, a white granular powder (Harden, *C. J.* 51, 40).—3. On heating with *malic acid* it yields the mono-toluide [178°], di-toluide [181°], and a tolyl-imide [116°] of *malic acid* (Bischoff, *B.* 23, 2048).—4. *Chloro-citryl chloride* forms $C_6H_4.N < \begin{smallmatrix} CO.CH \\ CO.OCH_2.CO.NHO_2H \end{smallmatrix}$ [214°] (Skinner

a. Ruhemann, *C. J.* 55, 289).—5. SO_2 , alcohol, and nitrous acid give rise to the 'sulphazide' $C_6H_4N_2SO_2$ [142°] (Limpricht, *B.* 20, 1241).—6. On *nitrification* of *o*-toluidine or its acetyl derivative NO_2 enters the *p*- and *o*- positions, but in presence of H_2SO_4 (10 pts.) the compound $C_6H_4Me(NO_2)(NH_2)$ [1:4:6] [107°] is formed (Nöltig a. Collin, *B.* 17, 265), together with the (1,2,6)-isomeride (Green a. Lawson, *C. J.* 59, 1018).—7. *Benzoic aldehyde* forms $C_6H_4CH:NC_6H_5$, an oil (316°) (Etard, *Bl.* [2] 39, 530; Pictet, *B.* 19, 1063).—8. *Hydrobenzamide* or warming forms the same body (310°) (Lachovitch, *M.* 9, 695).—9. Toluidine heated with toluidine hydrochloride and benzoic aldehyde in sealed tubes at 120° forms $C_6H_4.CH(C_6H_4Me.NH_2)_2$, a crystalline powder turning blue in the air (Ullmann, *J. pr.* [2] 36, 251).—10. The *methyl derivative* of *p*-oxy-benzoic aldehyde at 120° produces the compound $C_6H_4(OMe).CH:N.C_6H_5$ [32°] (Steinhart, *A.* 241, 340).—11. *Bromo-propionic acid* reacts, forming $C_6H_4N_2O_2$ [185°] (Mabery a. Krause, *B.* 22, 3308).—12. *α,β-Di-bromo-acrylic acid* produces pale-yellow needles [115°] (*M. a. K.*).—13. The hydrochloride heated with $MeOH$ at 250°–300° gives rise to di-methyl-toluidine, xylylidine $C_6H_4Me_2(NH_2)$ [4:3:1] and mesidine (Limpricht, *B.* 21, 640).—14. *Cyanogen* passed into an alcoholic solution forms crystalline $C_6H_4N_4$, which yields $B''H_2Cl_2$ and $B''2HNO_3$ (Bladin, *Bl.* [2] 41, 128).—15. On heating with S it yields $C_6H_4N_2S$ [120°] crystallising from alcohol in yellow plates and yielding a dibromide $C_6H_4Br_2N_2S$ [190°] (Gattermann, *B.* 22, 425).—16. $ClSO_3H$ in $CHCl_3$ forms $C_6H_4NH.SO_3H$, which yields $BAA_2.2aq$. Both the acid and its salts reproduce *o*-toluidine when treated with hot water (Traube, *B.* 23, 1656).

Salts (Beilstein a. Kuhlberg, *A.* 156, 66; Rosenstiehl).— $B'HCl_aq$. S. 37.4 at 15.5°. S. (alcohol) 100.— $B'_2H_2PtCl_6$. Decomposed by boiling water (difference from *p*-toluidine) (De Coninck, *Bl.* [2] 45, 131).— $B'_2H_2ZnCl_6$. White tables (Bibanooff, *Mom. scient.* [3] 4, 925).— $B'_2ZnCl_2.2aq$ (Lachovitch, *M.* 9, 513).— B'_2HgCl_4 [115°]. Prepared by shaking an alcoholic solution of the base with $HgCl_2$ (Klein, *B.* 11, 743). Crystalline powder, sol. alcohol and ether.— B'_4MnCl_4 .— $B'_4H_2CuCl_4$. Yellow crystalline pp. got by adding $CuCl_2$ to a solution of the hydrochloride (Pomey, *C. R.* 104, 365).— $B'HBr$. Trimetric prisms.— B'_2HgBr_2 [104°]. Leaflets (Klein, *B.* 13, 835).— B'_2ZnBr_2 (Leeds, *J.* 1882, 503).— $B'HI$. Trimetric prisms (Städel, *B.* 16, 28).— B'_2HgI_4 . White needles.— B'_2ZnI_2 .— B'_2Odl_2 .— B'_2HgCy_2 .— $B'_4H_2FeCy_4$: crystals.— $B'_2H_2Cu_2(SO_4)_2$. Formed by adding aqueous cupric sulphate and $NaHSO_4$ to a solution of the base in acetic acid (Denigès, *C. R.* 112, 870).— $B'HgH_2(SO_4)_2.aq$.— $B'_2H_2SO_4$. Crystals (Wellington a. Tollens, *B.* 18, 3318).— $B'_2H_2SO_4$. S. 7.8 at 22°. S. (89 p.c. alcohol) 1.6 at 21.5°.— $B'HNO_3$. S. 10 at 19°. S. (89 p.c. alcohol) 23.5 at 16.5°.— $B'_2H_2PO_4$. Crystals, *v. sol.* water (Lewy, *B.* 19, 1717). The salts $B'_2H_2PO_4$ and $B'_2H_2P_2O_7$ could not be prepared. Aniline sets free *o*-toluidine from $B'_2H_2PO_4$. *p*-Toluidine also sets free *o*-toluidine from its phosphate.— $B'HSCyCr(SCy)_2.2NH_4$. Red plates, *v. sol.* hot water (Christensen, *J. pr.* [2] 45, 862).—*Oxalate*: small plates. S. 2.38 at 21°. S. 84 p.c.

alcohol) 2.68 at 21°. S. (ether) .65 at 21°.—Chloroacetate $\text{C}_6\text{H}_4\text{ClO}_2$. [95°] (Bischoff, B. 21, 1257).—(β ?)-naphtholate [81°] (Dyson, C. J. 48, 470).

Formyl derivative $\text{C}_6\text{H}_4\text{NHCHO}$. [58°]. (288°). Plates (Ladenburg, B. 10, 1129; Tobias, B. 15, 2446). The crystalline polymeride [211°] is v. sol. hot HOAc, nearly insol. ether and cold alcohol.

Thioformyl derivative $\text{C}_6\text{H}_4\text{NH.CSH}$: [96°]; yellow needles; bitter taste; sol. alcohol and ether, insol. water. Formed by heating the formyl derivative with P_2S_5 . It dissolves unaltered in cold aqueous NaOH, and is reprecipitated by an acid. By distillation in vacuo it

forms di-tolyl-formamidine $\text{C}_6\text{H}_4\text{NH} \gg \text{CH}$ with

evolution of H_2S and CS_2 . By heating for 7 hours at 190° under pressure a crystalline compound $\text{C}_6\text{H}_4\text{N}_2\text{S}$ [160°] is formed with evolution of H_2S (Senier, B. 18, 2292; C. J. 47, 762).

Acetyl derivative $\text{C}_6\text{H}_4\text{NHAc}$. [109°] (Bedson a. King, C. J. 37, 753). (296°). S. 85 at 19°. Formed from the base and HOAc (Beilstein a. Kuhlberg, A. 156, 77; Alt, A. 252, 318), or by shaking it with water and Ac_2O (Hinsberg, B. 23, 2962). Converted by PCl_5 into the compound $\text{C}_6\text{H}_4\text{N}:\text{CClMe}$, which when carefully heated gives a base $\text{C}_6\text{H}_4\text{N}:\text{CMe.CH}_2\text{CCl}:\text{NC}_6\text{H}_5$ [53°], and when treated with excess of *o*-toluidine gives di-tolyl-acetamidine [69°]. Br in HOAc forms $\text{C}_6\text{H}_4\text{MeBr}(\text{NHAc})$ [1:6:2] [157°].

Chloro-acetyl derivative $\text{C}_6\text{H}_4\text{NH.CO.CH}_2\text{Cl}$. [112°]. Formed by the action of chloro-acetyl chloride on *o*-toluidine dissolved in benzene (Widman, J. pr. [2] 38, 299). Needles (from dilute alcohol). Converted by alcoholic potash into a pyrazine derivative [160°].

Di-chloro-acetyl derivative $\text{C}_6\text{H}_4\text{NH.CO.OHCl}_2$. Needles, volatile with steam (Rügheimer a. Hoffmann, B. 18, 2987).

Tri-chloro-acetyl derivative $\text{C}_6\text{H}_4\text{NH.CO.OCl}_3$. [67°]. Formed from hexachloro-acetone and *o*-toluidine (Cleez, A. Ch. [6] 9, 215). Needles, sl. sol. cold alcohol.

Bromo-acetyl derivative $\text{C}_6\text{H}_4\text{NH.CO.CH}_2\text{Br}$. [113°]. Formed from *o*-toluidine and bromo-acetyl bromide (Widman, J. pr. [2] 88, 298). Needles. Converted by alcoholic potash into $\text{C}_6\text{H}_4\text{N}_2\text{O}_2$ [160°].

Thio-acetyl derivative $\text{C}_6\text{H}_4\text{NH.CS.CH}_3$. [68°] (Wallach, B. 13, 529; 16, 147). Converted by NaOEt and EtBr into oily $\text{C}_6\text{H}_4\text{N}:\text{CMe.SEt}$ (262°).

Propionyl derivative $\text{C}_6\text{H}_4\text{NH.COEt}$. [87°]. (299° at 730 mm.). Formed from *o*-toluidine and propionic acid (Pictet a. Duparc, B. 20, 3421). Needles, sl. sol. hot water. Oxidised by KMnO_4 to propionyl-*o*-amido-benzoic acid [117°].

α -Bromo-propionyl derivative $\text{C}_6\text{H}_4\text{NH.CO.OHBr.CH}_2$. [131°]. Needles, insol. ligroin (Tigerstedt, B. 25, 2920).

Benzoyl derivative $\text{C}_6\text{H}_4\text{NHBz}$. [131°] (Gudeman, B. 21, 2553; [148°] (Brückner, A. 205, 130). Long broad needles. Yields benzoyl-*o*-amido-toluic acid on oxidation by KMnO_4 . PCl_5 forms $\text{C}_6\text{H}_4\text{N}:\text{CClC}_6\text{H}_5$ (Just, B. 19, 982).

Oxalyl derivative $\text{C}_6\text{O}_4(\text{NH.C}_6\text{H}_4)_2$

[131°]. Plates (from alcohol) (Bladin, Bl. [2] 41, 130).

Phthalyl derivative $\text{C}_6\text{H}_4\text{N:C}_6\text{H}_4\text{C}_2\text{H}_3\text{O}_2$. [182°]. (near 360°). Needles, sol. hot HOAc (Fröhlich, B. 17, 2679).

Phenacetyl derivative $\text{C}_6\text{H}_4\text{NH.CH}_2\text{CO.C}_6\text{H}_5$. [89°]. Formed from the base in alcohol and ω -bromo-acetophenone (Bischler, B. 25, 2865). Needles. Yields B'HCl and an acetyl derivative [92°].

***m*-Toluidine** $\text{C}_6\text{H}_4\text{Me.NH}_2$ [1:3]. (197°) (Beilstein a. Kuhlberg, A. 156, 83); (201°) (Buchka a. Schachtebeck, B. 22, 840); (205°) (Lorenz, A. 172, 180; Merz a. Müller, B. 20, 548). S.G. 25.998. S.N. 128.1. H.C.v. 964,600. H.C.p. 965,600. H.F. 2,900 (Petit, A. Ch. [6] 17, 155). Formed by reduction of *m*-nitro-toluene. Obtained also from *p*-toluidine by successive acetylation, nitration, saponification, diazotisation, boiling with alcohol, and reduction (Lorenz, B. 7, 448). Formed also by heating *m*-cresol with ZnBr_2 , ammonia, and NH_4Br at 800° (M. a. M.). Prepared from benzoic aldehyde by nitration, conversion into *m*-nitro-benzylidene chloride and reduction of this body by zinc and HCl (aq in the cold (Vienne a. Steiner, Bl. [2] 35, 428; Widman, B. 13, 676; Bl. [2] 36, 216; Ehrlich, B. 15, 2011; Harz, B. 18, 3398). *m*-Toluidine can be shown to exist in commercial toluidine by means of the nitroso-derivative of di-methyl-*m*-toluidine, since *o*- and *p*-di-methyl-toluidines do not give nitroso-derivatives (Wurster a. Riedel, B. 12, 1796).

Properties.—Oil. Its solution in $\text{H}_2\text{SO}_4\text{H}_2\text{O}$ is coloured yellowish-brown by CrO_3 and blood-red by HNO_3 . Its ethereal solution, shaken with water and a little bleaching-powder, is coloured reddish, the aqueous layer being brownish yellow. HNO_3 added to its solution in a mixture of H_2SO_4 and HOAc below 0° forms nitro-toluidine [134°] and some of its isomerides. Cyanogen passed into its alcoholic solution gives the compound $(\text{C}_6\text{H}_4\text{NH})_2\text{C}_2\text{N}_2$ [200°] which forms B'HCl , $\text{B}'_2\text{HNO}_3$, and $\text{B}'_2\text{H}_2\text{SO}_4$ (Clève a. Bladin, Bl. [2] 41, 129). Yields (4,2,1)-xylylidine when its hydrochloride is heated with MeOH at 200°–300° (Limpach, B. 21, 646).

Salts.— B'HCl . S. 96.3 at 12°. S. (94 p.c. alcohol) 61.9 at 9°.— $\text{B}'_2\text{H}_2\text{PtCl}_6$.— B'HNO_3 . S. 20.1 at 23.5°. S. (94 p.c. alcohol) 46 at 15°.— B'HBiI_4 (Kraut, A. 210, 323).— $\text{B}'_2\text{H}_2\text{SO}_4$. S. 6.25 at 14°. S. (94 p.c. alcohol) .41 at 15°.— $\text{B}'_2\text{H}_2\text{FeCy}_4$ (Eisenberg, A. 205, 270).— $\text{B'H}_2\text{C}_2\text{O}_4$. Silky needles. S. 2.65 at 13°. S. (94 p.c. alcohol) 1.77 at 15°. S. (ether) .13 at 15°.— $\text{B}'_2\text{H}_2\text{C}_2\text{O}_4$. White plates, S. 1.45 at 15°. S. (94 p.c. alcohol) .96; S. (ether) .128 at 15.5°.— $\text{B}'_2\text{H}_2\text{C}_2\text{O}_4$ aq. Very unstable.

Formyl derivative $\text{C}_6\text{H}_4\text{NHCHO}$. (278° at 724 mm.) (Niemientowski, B. 20, 1892). Converted by long boiling into $\text{C}_6\text{H}_4\text{N}:\text{CH.NHC}_6\text{H}_5$ [123°].

Acetyl derivative $\text{C}_6\text{H}_4\text{NHAc}$. [65°]. (803°). S. .44 at 13°.

Di-chloro-acetyl derivative $\text{C}_6\text{H}_4\text{NH.CO.OHCl}_2$. [100°]. Silky plates (Rügheimer a. Hoffmann, B. 18, 2988).

Benzoyl derivative $\text{C}_6\text{H}_4\text{NHBz}$. [125°] (Just, B. 19, 983).

Phthalyl derivative $\text{C}_6\text{H}_4\text{N:C}_6\text{H}_4\text{C}_2\text{H}_3\text{O}_2$

[153°]. Needles, v. sol. HOAc (Fröhlich, *B.* 17, 2679).

p-Toluidine $C_7H_7Me(NH_2)$ [1.4]. [45°] (Städeler); [42-8°] (Mills). (198°) (M. a. H.); (206°) (Städeler, *J. pr.* 96, 65). S.G. 1.046. S. 35 at 11.5°. H.C.p. 958,800. H.C.v. 957,860. H.F. 9,700 (Petit, *C. R.* 107, 266). S.V. 128,700. Formed by reduction of *p*-nitro-toluene (Musprratt a. Hofmann, *A.* 54, 1; 66, 144; Noad, *A.* 63, 305; Hugo Müller, *Z.* 1864, 161; Sell, *C. J.* 16, 186; v. also *o*-TOLUIDINE). Formed also by heating *p*-cresol with ammoniacal $ZnCl_2$ (Buch, *B.* 17, 2637; Merz a. Müller, *B.* 20, 545) and by treating methyl-aniline hydrochloride at 350° (Hofmann, *B.* 5, 720). On sulphonating a mixture of *o*- and *p*-toluidine the *o*-toluidine is first attacked and the *p*-toluidine can then be distilled off.

Properties.—Plates (from ligroin or dilute alcohol). Its solution in H_2SO_4 is turned yellow by CrO_3 and blue by HNO_3 , in the latter case changing to red and finally brown (Rosenstiehl, *Bl.* 10, 200). Bleaching-powder does not colour its solution in water or ether. PbO_2 and HOAc diluted with water or alcohol give a bright red colour (Lauth, *C. R.* 111, 975). When boiled with water, crystals of an efflorescent hydrate separate on cooling (Lewy, *B.* 19, 2728).

Reactions.—1. Oxidised by $KMnO_4$, alkaline K_2FeC_7 , or chromic acid to $C_7H_7N_2$ or $C_7H_7Me(NHCH_2)_2(NH_2)$ [1:2:5:4], which may be readily reduced to $C_7H_7Me(NHCH_2)_2(NH_2)$ crystallising from alcohol in colourless plates [166°], readily re-oxidised to $C_7H_7N_2$ (Barsilowsky, *A.* 207, 102, 118; *J. R.* 1887, 132; Perkin, *C. J.* 35, 728; 37, 546; Klinger a. Pitschke, *B.* 17, 2489; Green, *C. J.* 63, 1395). The compound $C_{12}H_{11}N_2$ crystallises from xylene in dark-red plates [227°], dissolving in acids, forming maroon-red liquids, quickly decomposing with separation of *p*-toluidine. Conc. H_2SO_4 dissolves $C_{12}H_{11}N_2$, forming a greenish-blue liquid which on warming becomes wine-red with production of *p*-toluidine.—2. Oxidised by CrO_3 and HOAc to toluene-azo-toluene $C_7H_7N_2C_6H_5$.—3. Nitrous acid forms $C_7H_7N_2.NHCH_2$. When $NaNO_2$ is added to a solution of the hydrochlorides of *o*- and *p*-toluidine, the *o*-toluidine is first attacked, yielding $C_7H_7N_2C_6H_4NH_2$ and can thus be removed when mixed with *p*-toluidine (Wülfing, *D. P. J.* 263, 260).—4. Substituents usually enter positions 3 and 5 [Me=1] but when *p*-toluidine or its acetyl derivative is dissolved in H_2SO_4 (20 pts.) and nitrated the compound $C_7H_7Me(NO_2)(NH_2)$ [1:2:4] is formed instead of the (1,3,4)-isomeride (Nölting a. Collin, *B.* 17, 263).—5. Bromine in conc. $HClAq$ at 0° forms $C_7H_7Br_2Me(NH_2)$ [5:3:1:4]; but $C_7H_7BrMe(NH_2)$ [2:1:4] is formed in presence of conc. H_2SO_4 (Hafner, *B.* 22, 2538, 2902).—6. ICl forms $C_7H_7I_2Me(NH_2)$ [5:3:1:4] (Michael a. Norton, *B.* 11, 107).—7. Chlorine passed into *p*-toluidine dissolved in H_2SO_4 at 0° forms $C_7H_7MeCl(NH_2)$ [1:3:4] and larger quantities of its (1,2,4)-isomeride. In $HClAq$ (40 p.c.) the chief product is $C_7H_7MeCl_2(NH_2)$ [1:3:5:4] (Hafner).—8. Cyanogen passed into an alcoholic solution forms $C_7H_7N_4$ or $(C_7H_7N_2)_2C_2N_2$ crystallising in pearly scales [222°-230°] and yielding the crystalline salts B_2HCl , B_2HNO_3 , $B_2H_2SO_4$, 6aq, and $B_2H_2C_2O_4$

(Hofmann, *C. J.* 1, 170; *A.* 66, 144; Clève a. Bladin, *Bl.* [2] 41, 125). The mother-liquor contains $C_7H_7N_2$ [182°] which yields the salts $B'HCl$ 8aq (a red powder) and $B'H_2PtCl_6$. The compound $C_{12}H_{11}N_2$ is also formed when *p*-toluidine is heated with oxalimido-ether at 100° (Vorländer, *B.* 24, 805).—9. Cyanuric chloride forms $C_7N_3(NHCH_2)_3$ [283°] (Klason, *J. pr.* [2] 33, 294).—10. Chloro-acetic acid ($\frac{1}{2}$ mol.) forms $C_7H_7NH.CH_2.CO_2H$, while chloro-acetamide forms $C_7H_7NH.CH_2.CO.NH_2$ (P. F. Meyer, *B.* 8, 1158). An alcoholic solution of chloro-acetic acid and $HCyS$ yields $C_{11}H_{11}N_2SO_2$ [176°-182°] (Nencki, *J. pr.* [2] 16, 1).—11. Dichloro-acetic acid forms tolylamido-methyl-oxindole.—12. Chloral reacts, with formation of $CCl_3.CH(NHCH_2)_2$ [115°] (Wallach, *A.* 173, 278). When chloral is warmed with an alcoholic solution of *p*-toluidine there is also formed $CCl_3.CH(OEt).NHCH_2$ [77°].—13. Aldehyde forms crystalline $CH_3.CH(NHCH_2)_2$ [c. 60°].—14. Furfuraldehyde added to a hot alcoholic solution of *p*-toluidine and its hydrochloride forms brown amorphous $C_{12}H_{11}N_2O_2$, which yields $B'HCl$ and $B'HNO_3$ both crystallising in purple needles (Stenhouse, *A.* 156, 203).—15. Nascent formic aldehyde produces a base $C_{11}H_{11}N_2$ [134°] which is converted by nitrous acid with evolution of CO_2 into $C_{11}H_{11}N_2O_2$ [260°-264°] (Tollens, *J. pr.* [2] 36, 225).—16. Benzoic aldehyde at 100° reacts, forming $C_6H_5.CH(NHCH_2)_2$ [100°] (326° i.v. at 723 mm.), which changes at 160° into an isomeride [120°-125°] and is converted by Br in CS_2 into $C_{11}H_{11}Br_2N$ [160°-165°] (Schiff, *Z.* 1865, 400; Mazzara, *J.* 1880, 566; Pictet, *B.* 19, 1063). In the action of *p*-toluidine and its hydrochloride on benzoic aldehyde at 120° there is produced $C_{12}H_{11}N_2$ [178°] and $C_6H_5.CH(C_7H_7Me.NH_2)_2$ [186°] (c. 430°), which yield a di-acetyl derivative [218°] and a di-benzoyl derivative [196°] (Ullmann, *J. pr.* [2] 36, 267).—17. *p*-Methoxybenzoic aldehyde forms $C_7H_7(OMe).CH(NC_6H_5)_2$ [92°] (Steinhart, *A.* 241, 832).—18. *p*-Methoxybenzophenone chloride yields the compound $C_7H_7(OMe).CPh.NC_6H_5$ [96°] Hantzsch a. Kraft, *B.* 24, 8520).—19. An ethereal solution of $C_6H_5.CCl.NSO_2Ph$, obtained from benzene sulphonic anilide and PCl_5 , forms the compound $C_6H_5.C(NHCH_2)_2.NSO_2Ph$, which separates in monoclinic crystals; $a:b:c = .650:1:533$; $\beta = 69^\circ 16'$, insol. water (Wallach a. Gossmann, *A.* 214, 216).—20. Alcohol, SO_2 , and nitrous acid form the sulphazide $C_{11}H_{11}N_2SO_2$ [140°] (Limpricht, *B.* 20, 1241).—21. Heated with persulphocyanic acid it gives *p*-tolyl-thiobiuret (*B.* 17, 584).—22. On heating with sulphur it yields dehydrothiotoluidine and primuline; v. PRIMULINE.—23. Diazobenzene chloride yields $C_7H_7N_2.NHCH_2$ [85°] which is identical with the product of the action of *p*-diazotoluene chloride on aniline (Nölting a. Binder, *B.* 20, 8005).—24. Bromo-propionic acid forms di-tolyl-acetamide $C_{11}H_{11}N_2$ [120°] (Mabery a. Krause, *B.* 22, 3307), which is also formed by the action of HOAc and PCl_5 on *p*-toluidine (Hofmann, *Pr.* 15, 55).—25. Itaconic acid in boiling aqueous solution forms $C_7H_7N \cdot CO \cdot CH_2$ [185°] (Scharfenberg, *A.* 254, 150).—26. Acetyl-citric anhydride dissolved in chloroform forms

$C_6H_5O(CO_2H)(CO.NHC_2H_5)_2$ [189°] Klingemann, *B.* 22, 987.—27. *Malic acid* at 160° yields $C_6H_5O(CO.NHC_2H_5)_2$ [208°] (Bischoff, *B.* 23, 2045).—28. The hydrochloride heated with $MeOH$ yields $C_6H_5Me_2(NH_2)$ [1:3:4] (Limpach, *B.* 21, 640).—29. *Ethylene oxide* forms oxyethyl-*p*-toluidine (Demole, *B.* 7, 635).—30. $SOCl_2$ forms thionyl-toluidine (*q. v.*)—31. $POCl_3$ forms $PO(NHC_2H_5)_2$ [192°], which yields $PO(NHC_2H_5Br)_2$ [180°] and $PO(NH.C_2H_5.NO_2)_2$ [247°] (Rudert, *B.* 26, 569). Another product of the action of $POCl_3$ is $POCl(NHC_2H_5)_2$, whence water forms $HO.PO(NHC_2H_5)_2$ [124°].—32. $PSCl_3$ forms $PS(NHC_2H_5)_2$ [185°].

Salts.— $B'HCl$. *S.* 22.9 at 11°; *S.* (89 p.c. alcohol) 25 at 17°.— $B'HAuCl_4$.— $B'_2H_2PtCl_6$. Not decomposed by boiling water (De Coninck, *Bl.* [2] 45, 131).— B'_2PtCl_2 (Gordon, *B.* 3, 177; Cochin, *Bl.* [2] 31, 499).— $B'_2H_2PtCy_4$ (Scholz, *M.* 1, 905).— $B'PtClEt_2PO_4$ (Saillard, *Bl.* [2] 18, 111).— $B'_2PtClMe_2PO_4$.— $B'PtCl_2Et_2PO_4$ (Cochin, *J.* 1878, 315).— B'_2ZnCl_23aq (Lachovitch, *M.* 9, 513).— $B'_2H_2ZnCl_2$ (Gräffinghoff, *Z.* 1865, 599).— B'_2HgCl_2 [125°]. Thick needles, sol. alcohol and ether (Klein, *B.* 11, 743).— B'_2NiCl_2EtOH . Green pp. (Lippmann a. Vortmann, *B.* 12, 81).— B'_2CoCl_2 . Blue needles.— $B'_2H_2SnCl_4$. Monoclinic crystals (Hjortdahl, *J.* 1882, 535).— $B'_2H_2CuCl_2$ (Pomey, *C. R.* 104, 300).— B'_2MnCl_2 (Leeds, *J.* 1882, 503).— $B'_2UO_2Cl_2$.— $B'HBBr$. Plates (Städel, *B.* 16, 28).— B'_2HgBr_2 [121°]. Plates (Klein, *B.* 13, 835).— B'_2ZnBr_2 .— B'_2CdBr_2 .— $B'HI$.— B'_2HgI_2 [81°].— $B'HBiI_4$ (Kraut, *A.* 210, 324).— $B'_2(H_2SO_4)_2HI_2$ (Jørgensen, *J. pr.* [2] 14, 386).— B'_2ZnI_2 .— B'_2CdI_2 .— $B'HNNO_3$. *S.* 17.7 at 23.5°; *S.* (89 p.c. alcohol) 42 at 20°.— B'_2AgNO_3 [101°] (Mixer, *Am.* 1, 239).— $B'_2Cd(NO_3)_2$.— $B'_2Hg(NO_3)_2$.— $B'_2H_2SO_4$. *S.* 5.06 at 22°; *S.* (84 p.c. alcohol) 1.3 at 23°.— $B'_2H_2SO_4$. Crystals, converted into $B'_2H_2SO_4$ by water (Tollens, *B.* 18, 3312).— $B'_2Ag_2SO_42aq$ (Mixer).— $B'_2H_2PO_4$. Thick needles, v. sl. sol. cold water (Lewy, *B.* 19, 1717).— $B'_2(NH_4Ph)_2H_2CoCy_21\frac{1}{2}aq$ (Weselsky, *J.* 1869, 314).— $B'_2H_2CoCy_22aq$.— B'_2HgCy_2 .— $B'HO_3(SCy)_2NH_2$. Plates (Christensen, *J. pr.* [2] 45, 362).— $B'_2CuH_2(SO_4)_2$. Yellowish-white hexagonal plates.— $B'_2HgH_2(SO_4)_2aq$ (Denigès, *C. R.* 112, 870).—Oxalate $B'_2H_2C_2O_4$ 1aq (Bornemann, *B.* 22, 2710). *S.* 8.7 at 14°; *S.* (84 p.c. alcohol) 48 at 22°. Insol. ether.—Chloroacetates $B'_2H_2C_2ClO_2$ [102°] (Baralis, *J.* 1884, 698).— $B'_2C_2H_4ClO_2$ [141°]. (B.) [186°] (Duisberg, *B.* 18, 194).— $B'_2C_2HClO_2$ [137°].—Trichloro-lactate $B'_2C_2H_2Cl_3O_2$ [136°].—Mucate $B'_2C_2H_4O_2$. Yellowish crystals, sol. hot water.—Picrate $B'_2C_2H_2N_3O_7$ [169°] (Smolka, *M.* 6, 923). *S.* 5.4 at 18.5°; *S.* (95 p.c. alcohol) 4.29 at 18°.—Phenate [31.1°]. Got by heating *p*-toluidine with phenol (Dyson, *C. J.* 43, 468). Needles (from lignin).—Compound with picramide $B'_2C_2H_2(NO_2)_2NH_2$. Black needles with green reflex (Mertens, *B.* 11, 843).

Formyl derivative $C_6H_5.NK.CO$. [45°] (Hübner a. Rudolph, *A.* 209, 371); [52°] (Tobias, *B.* 15, 2446); [53°] (Bamberger a. Wulz, *B.* 24, 2080). Formed by boiling *p*-toluidine with formic acid or, together with the oxalyl derivative $C_6H_5(NHC_2H_5)_2$ [263°], by heating *p*-toluidine oxalate. Prisms. Converted by heating with P_2S_5 into $C_6H_5.NH.CHS$ [174°]

(Senier, *B.* 18, 2294; *C. J.* 47, 766). Yields $C_6H_5.NNa.CHO$ aq.

Acetyl derivative $C_6H_5.NHAc$. [147°] (Hübner a. Wallach, *A.* 154, 302; Kelbe, *C. J.* 44, 915). (807°) (Beilstein a. Kuhlberg, *A.* 156, 74). *S.* 0.89 at 22°. Dimorphous, crystallising in monoclinic forms; $a:b:c = 1.216:1:788$; $\beta = 106^\circ 7'$, and also in trimetric crystals; $a:b:c = 651:1:329$ (Panebianco, *G.* 9, 362). Oxidised by $KMnO_4$ to acetyl-*p*-amido-benzoic acid (Hofmann, *B.* 9, 1299). Oxidised in like manner in the animal body (Jaffe a. Hilbert, *H.* 12, 295). PCl_5 forms a liquid product which solidifies when strongly cooled, the crystals doubtless being $C_6H_5.NH.CCl_2.CH_3$. This readily splits up into HCl and $C_6H_5.N.CCl_2.CH_3$. This is a colourless solid which is converted by Aq into acetyl-*p*-toluidine; by toluidine into di-tolyl-acetamidine. The chloro-imide $C_6H_5.N.CCl_2.CH_3$ at 100° forms a base $C_6H_5.N.Cl$ [72°], which may be crystallised from alcohol. It is probably $C_6H_5.N.CMe.CH_2.CCl_2.NC.H$. It is decomposed by moist air or water with production of $MeC(NC.H)_2NC.H$, $HOAc$ and $MeCONHC.H$, and by heat with production of an amorphous base $C_6H_5.N_2$ (Wallach a. Fassbender, *A.* 214, 202). Nitrous acid converts acetyl-*p*-toluidine into $C_6H_5.NAc.NO$ [80°] (O. Fischer, *B.* 10, 959).

Chloro-acetyl derivative $C_6H_5.NH.CO.CHCl_2$. [162°]. Needles (Tommasi, *Bl.* [2] 19, 400; Meyer, *B.* 8, 1154).

Di-chloro-acetyl derivative $C_6H_5.NH.CO.CHCl_2$. [153°] (Rügheimer a. Hoffmann, *B.* 18, 2980).

Tri-chloro-acetyl derivative $C_6H_5.NH.CO.CCl_3$. [80°] (C.); [102°] (J.). *S.* (alcohol) 12.5 at 14°. Formed from *p*-toluidine and CCl_3CO (Cloe, *A. Ch.* [6] 9, 145), and also from *p*-toluidine and CCl_3COCl (Judson, *B.* 3, 784).

Bromo-acetyl derivative $C_6H_5.NH.CO.CH_2Br$. [164°]. Needles (Abenius, *J. pr.* [2] 40, 438) converted by alcoholic potash into an azine and $C_6H_5.NH.CO.CH_2OEt$ [32°] which is v. e. sol. alcohol.

Thio-acetyl derivative $C_6H_5.NH.CS.CH_3$. [131°]. Formed from the acetyl derivative and P_2S_5 (Jacobsen a. Ney, *B.* 22, 906). Got also by heating tolyl-acetamidine with CS_2 at 100°, or di-tolyl-acetamidine with H_2S (Bernthsen a. Trompeter, *B.* 11, 1759; Wallach a. Pannes, *B.* 13, 529). Converted by $NaOEt$ and $EtBr$ into oily $C_6H_5.N.CMe.SET$ (272°) (Wallach a. Wüsten, *B.* 16, 147).

α -Bromo-propionyl derivative $C_6H_5.NH.CO.CHBBr$. [125°] (Tigerstedt, *B.* 25, 2921). Plates, v. sol. $CHCl_3$.

Benzoyl derivative $C_6H_5.NHBz$. [158°]. (232°). Formed from *p*-toluidine and $BzCl$ (Jaillard, *Z.* 1865, 440; Kelbe, *B.* 8, 875; Hübner, *A.* 208, 310; Wallach, *A.* 214, 217; Gude-man, *B.* 21, 2553; Müller, *B.* 22, 2404). Needles, v. sol. alcohol. Converted by PCl_5 into $C_6H_5.N.CCl_2.C_6H_5$ [52°] (Just, *B.* 19, 980) crystallising from ligroin in prisms.

***p*-Nitro-benzoyl derivative** $C_6H_4(NO_2).CO.NHC_2H_5$. [197°]. Formed from *p*-toluidine and *p*-nitro-benzoyl chloride. Yellow needles (Gattermann, *B.* 25, 1082). Converted by PCl_5 into $C_6H_4(NO_2).COCl.NHC_2H_5$ [119°] crystallising in golden prisms.

Phenacyl derivative

$C_6H_5NH.CH_2.CO.C_6H_5$. [127°]. Formed from *o*-bromo-acetophenone and *p*-toluidine in alcohol (Bischler, *B.* 25, 2866). Yellow prisms, yielding $BHCl$ and an acetyl derivative [89°] crystallising in white needles (from alcohol).

Phthalyl derivative $C_6H_5N:C_2O_2:C_6H_5$. [205°] (Fröhlich, *B.* 17, 2679).

References.—BROMO-, DIBROMO- IODO-, BROMO-NITRO-, CHLORO-, TRI-CHLORO-NITRO-, IODO-, NITRO-, and NITROSO-TOLUIDINES.

TOLU-($\alpha\beta$)-NAPHTHAZINE $C_{11}H_{12}N_2$ *i.e.*

Formed by oxidation of a mixture of tolylene-*o*-diamine (4 mol.) and (β)-naphthol (1 mol.) with K_2FeCy_6 . Formed also, together with the isomeride [169°], by the action of (β)-naphthoquinone on tolylene-*o*-diamine (Witt, *B.* 20, 577). Dissolves in conc. H_2SO_4 with violet-red colour. Forms with its isomeride a molecular compound [142°].

Tolu-($\alpha\beta$)-naphthazine $C_{11}H_{12}N_2$ *i.e.*

Formed as above, and also, together with amido-benzene *p*-sulphonic acid, by boiling sulphobenzene-azo-(β)-naphthyl-*p*-tolyl-amine with dilute H_2SO_4 , and by boiling 'wool black' $C_6H_4(SO_3H).N_2.C_6H_4(SO_3H).N_2.C_6H_4.NH.C_6H_5$ with dilute H_2SO_4 (Witt, *B.* 20, 577). Yellow crystals, *v.* sl. sol. alcohol. Conc. H_2SO_4 forms a brownish-red solution.

TOLUNITRANILIC ACID *v.* NITRO-DI-OXY-TOLUQUINONE.

TOLUOIN *v.* DI-METHYL-BENZOIN.

TOLUOL *v.* TOLUENE.

TOLUPHOSPHINIC ACID *v.* PHOSPHOTOLUIC ACID.

TOLUQUINOL *v.* HYDROTOLUQUINONE.

TOLUQUINOLINE *v.* METHYL-QUINOLINE.

TOLUQUINONE $C_8H_6O_2$ *i.e.*

Formation.—1. By oxidation of tolylene-*p*-diamine or of *o*-toluidine (Nietzki, *B.* 10, 832, 1934; *A.* 215, 158; Ladenburg, *B.* 10, 1128).—2. By boiling crude creosol with MnO_2 and dilute H_2SO_4 (Carstanjen, *J. pr.* [2] 23, 425). Separated from accompanying xyloquinone by reduction with SO_2 , crystallising the hydrotoluquinone from benzene, and re-oxidising by fuming HNO_3 .—3. By oxidation of *m*-xyldine (Nölting a. Baumann, *B.* 18, 1151).

Preparation.—20 g. of *o*-toluidine are dissolved in 600 c.c. of water containing 160 g. of H_2SO_4 ; 20 g. of finely powdered potassium bichromate are added by degrees, with continual agitation, keeping the temperature at 10°–15°. After standing over night, 83 g. more $K_2Cr_2O_7$ are added; the quinone is then extracted with ether, dried over $CaCl_2$, and the ether removed by dis-

tillation. The yield is about 86 p.c. of the theoretical quantity (Schniter, *B.* 20, 2283).

Properties.—Golden-yellow plates smelling like quinone. Very volatile. *M.* sol. hot water, *v.* sol. alcohol and ether. Its aqueous solution is turned brown by alkalis. SO_2 reduces it to hydrotoluquinone. Dilute (50 p.c.) H_2SO_4 changes it to isotoluquinone ($C_8H_6O_2$), a powder not melted at 300° (Spica, *G.* 12, 225). An aqueous solution of toluquinone mixed with one of hydrotoluquinone deposits steel-blue needles of the quinhydrone [52°], *v.* a. sol. water. *o*-Nitro-aniline forms [2:1:4:6] $C_6H_5MeO_2.NH.C_6H_5NO_2$, crystallising from alcohol in red crystals decomposing at 200° (Leicester, *B.* 23, 2796). Nitro-*p*-toluidine $C_6H_5Me(NO_2).NH_2$ [1:3:4] forms a homologous body.

Chlorimide $C_6H_5Me \left\langle \begin{array}{c} O \\ NCl \end{array} \right\rangle [12]. \quad [88^\circ]$

(Hirsch, *B.* 18, 1514). Formed by the action of a solution of bleaching-powder on the hydrochloride of amido-*o*-cresol. Yellow prisms (from alcohol) volatile with steam. Decomposes violently at 100°–115°. By digestion with $NaHSO_4$ for several hours it is converted into amido-cresol sulphonic acid.

Chlorimide $C_6H_5Me \left\langle \begin{array}{c} O \\ NCl \end{array} \right\rangle [12]. \quad [75^\circ]$

Made in like manner from amido-*m*-cresol (Staedel, *A.* 259, 218). Yellow prisms (from alcohol), volatile with steam.

Oxim $C_6H_5MeO(NOH)[2:1:4]$. **Nitroso-*o*-cresol**. [135°]. Formed by the action of nitrous acid on *o*-cresol (Nölting a. Kohn, *B.* 17, 870). Formed also by the action of hydroxylamine hydrochloride on toluquinone (Goldschmidt a. Schmid, *B.* 17, 2063). Needles (from water), decomposed by fusion. *V.* sol. alcohol and ether. Yields nitro-cresol [95°] on oxidation.— $NaA/3aq.$ — KA : brown needles, *v.* sol. water.

Oxim $C_6H_5MeO(NOH)[2:4:1]$. **Nitroso-*m*-cresol**. Formed by boiling nitroso-di-methyl-*m*-toluidine with dilute (10 p.c.) $NaOHAq$ (Wurster a. Riedel, *B.* 12, 1799). Formed also by the action of $NO_2.SO_3H$ on *m*-cresol and water at 0° (Bertoni, *G.* 12, 303). Small needles (from water). Decomposes at 145°–150°. *Sl.* sol. hot water. Gives Liebermann's reaction. Forms an acetyl derivative $C_6H_5MeO(NOAc)$ [92°] crystallising in large prisms.

Di-oxim $C_6H_5Me(OH)_2[2:1:4]$. Formed by the action of hydroxylamine on either mono-oxim (Nietzki a. Guitermann, *B.* 21, 430) or by boiling nitroso-*o*- or *m*-toluidine with hydroxylamine hydrochloride (Mehne, *B.* 21, 729). Yellow needles, exploding at 220°–234°. *v.* sl. sol. benzene, sol. hot water, alcohol, and ether. Reduced by tin and $HClAq$ to tolylene-*p*-diamine. Alkaline K_2FeCy_6 forms di-nitroso-toluene. Ac_2O forms $C_6H_5Me(NOAc)_2$ [120°], crystallising from alcohol in colourless needles.

Ditolylimide $C_6H_5Me(NC.H)_2$. [146°]. Formed by oxidation of tolylene-di-tolyl-diamine in alkaline solution (Green, *C. J.* 63, 1409). Red prisms, *v.* sol. alcohol, *v.* e. sol. benzene.

References.—DI-BROMO-, CHLORO-, IODO-, and OXY-TOLUQUINONE.

TOLUQUINOXALINE *v.* METHYL-QUINOXALINE.

***o*-TOLURIC ACID** $C_{10}H_{11}NO_2$ *i.e.*

[162.5°]. Formed from toluyl chloride, amido-acetic acid, and NaOH (Gleditsch a. Möller, *A.* 250, 876). Found in the urine of dogs that have taken *o*-toluic acid. Thick plates, sol. water.

m-Toluric acid. [139°]. Formed as above, and also when *p*-xylene or *m*-toluic acid is administered to a dog (G. a. M.; cf. Schultzen a. Naunyn, *Z.* 1868, 29). M. sol. water.— ZnA'_2 4aq.— CuA'_2 6aq.

p-Toluric acid. [161°]. Formed from *p*-toluyl chloride and glyccoll (G. a. M.) and also by passage of *p*-xylene or *p*-toluic acid through the animal body (Kraut, *A.* 98, 360). Plates (from water), sl. sol. cold water, v. sol. alcohol.— CaA'_2 3aq.— BaA'_2 5aq.— AgA' .

TOLUYL. The radicle $\text{CH}_2\text{C}_6\text{H}_4\text{CO}$. The same name has been given to the radicle $\text{CH}_2\text{C}_6\text{H}_4\text{CH}_2$, which is isomeric with xylyl, and has also been called tolyl, but may be more conveniently named methyl-benzyl. Toly is $\text{CH}_2\text{C}_6\text{H}_5$.

o-TOLUYL-ACETIC ACID

Ethyl ether $\text{C}_6\text{H}_4\text{Me.CO.CH}_2\text{CO}_2\text{Et}$. Oil, got by boiling the nitrile with alcohol and HCl. Gives a violet colour with FeCl_3 .

Nitrile $\text{C}_6\text{H}_4\text{CO.CH}_2\text{CN}$. [74.4°]. Formed by boiling *o*-toluyl-cyano-acetic ether with water (Haller, *C. R.* 108, 1117). Prisms, sol. alcohol and alkalis. Diazobenzene chloride and NaOH form $\text{O}_2\text{H}_2\text{CO.CH}_2\text{C}_6\text{H}_4\text{N}_2\text{C}_6\text{H}_5$. [125°]. Cold alcoholic HCl forms the hydrochloride of $\text{C}_6\text{H}_4\text{CO.CH}_2\text{C}(\text{NH})\text{OEt}$ [116°].

TOLUYL-ACRYLIC ACID $\text{C}_6\text{H}_4\text{O}_2$ i.e.

$\text{C}_6\text{H}_4(\text{CH}_2)\text{CO.CH:CH.CO}_2\text{H}$. [188°]. Formed by the action of AlCl_3 on a mixture of maleic anhydride and toluene (Pechmann, *B.* 15, 888).

TOLUYL ALCOHOL v. **TOLYL-CARBINOL**.

TOLUYLAMIDE v. *Amide of Toluic acid*.

p-TOLUYL-*o*-BENZOIC ACID $\text{C}_6\text{H}_4\text{O}_2$ i.e.

[1:4] $\text{C}_6\text{H}_4\text{Me.CO.C}_6\text{H}_4\text{CO}_2\text{H}$ [1:2]. *Phenyl tolyl ketone carboxylic acid*. Mol. w. 240. [146°]. Formed by the action of phthalic anhydride on toluene in presence of AlCl_3 (Friedel a. Crafts, *A. Ch.* [6] 14, 447; *C. R.* 92, 833). Prisms (containing aq) (from alcohol-toluene), v. sl. sol. hot water. Its dilute aqueous solution tastes sweet. Potash-fusion yields benzoic and *p*-toluic acids. Warm conc. H_2SO_4 forms (β)-methyl-anthraquinone. — BaA'_2 4aq. — CdA'_2 $\frac{1}{2}$ aq. — CuA'_2 4aq.

Methyl ether MeA' . [53°].

Ethyl ether EtA' . [69°].

Toluyl-benzoic acid $\text{C}_6\text{H}_4\text{CO.C}_6\text{H}_4\text{CO}_2\text{H}$. [222°]. Formed by oxidation of di-tolyl-methane and of *u*-di-tolyl-ethane (Weiler, *B.* 7, 1184; Ador a. Crafts, *C. R.* 85, 1163; O. Fischer, *B.* 7, 1195; Anschütz, *A.* 235, 816). Slender needles (from MeOH), sl. sol. hot water.— KA' : tufts of long needles.— AgA' .

Reference.—DI-CHLORO-TOLYL-BENZOIC ACID.

TOLUYLENE v. **TOLYLENE**.

p-TOLUYL-PROPIONIC ACID $\text{C}_{11}\text{H}_{12}\text{O}_2$ i.e.

$\text{C}_6\text{H}_4\text{CO.CH}_2\text{CH}_2\text{CO}_2\text{H}$. [127°] (C); [126°] (B). Formed by the action of succinyl chloride or succinic anhydride on toluene and AlCl_3 (Claus, *B.* 20, 1378; Buroker, *B.* [2] 49, 448). Plates or needles (from water), v. sol. ether.— BaA'_2 4aq: sol. hot water.— AgA' : small needles, insol. Aq.

o-TOLUYL-TOLUIC ACID. *Lactone*

$\text{C}_6\text{H}_4\text{C}(\text{CH}_2\text{C}_6\text{H}_4\text{CO})_2$. [93°]. Got from nitro-tolyl-

methylene-phthalide, HIAg , and P (Heilmann, *B.* 23, 8166). Thin prisms. Converted by alcoholic NH_3 into $\text{C}_6\text{H}_4\text{C}(\text{CH}_2\text{C}_6\text{H}_4\text{CO.NH}_2)_2$ [196°].

oo-DITOLYL $\text{C}_{12}\text{H}_{14}$ i.e.

[1:2] $\text{C}_6\text{H}_4\text{Me.C}_6\text{H}_4\text{Me}$ [1:2]. Mol. w. 182. (272°). S.G. $\frac{10.5}{4}$ 9945. Formed from *o*-bromo-toluene and Na (Fittig, *A.* 139, 178). Liquid.

mm-ditolyl [1:3] $\text{C}_6\text{H}_4\text{Me.C}_6\text{H}_4\text{Me}$ [1:3]. (280°) (Schultz, *B.* 17, 468); (288°) (Perrier, *C. R.* 114, 484); (289°) (Stolle, *B.* 21, 1096). S.G. $\frac{10}{4}$ 9993. Formed by diazotising di-amido-*o*-ditolyl and boiling the product with alcohol. Formed also by the action of Na on *m*-bromo-toluene (P.), and by reduction of di-oxy-*m*-ditolyl and di-chloro-*m*-ditolyl. Oil; yields diphenyl di-*m*-carboxylic acid and isophthalic acid on oxidation.

pp-ditolyl [1:4] $\text{C}_6\text{H}_4\text{Me.C}_6\text{H}_4\text{Me}$ [1:4]. [121°]. S.V. 198.0. Formed by adding Na to a solution of *p*-bromo-toluene in toluene (Zincke, *B.* 4, 396; Longuinine, *B.* 4, 514). Monoclinic prisms (from ether). Yields on oxidation *p*-tolyl-benzoic acid [244°] and diphenyl di-*p*-carboxylic acid (Carnelley, *C. J.* 32, 653). SbCl_5 at 360° forms CCl_4 and per-chloro-diphenyl.

om-Ditolyl [1:2] $\text{C}_6\text{H}_4\text{Me.C}_6\text{H}_4\text{Me}$ [1:3]. (270°). Formed from [2:4:1] $\text{C}_6\text{H}_4\text{Me}(\text{NH}_2)\text{C}_6\text{H}_4\text{Me}(\text{NH}_2)$ [1:3:4] by elimination of amidogen by the diazo-reaction (Schultz, *B.* 17, 471). Yields isophthalic acid on oxidation by CrO_3 .

op-Ditolyl [1:2] $\text{C}_6\text{H}_4\text{Me.C}_6\text{H}_4\text{Me}$ [1:4]. (272°–280°). Formed from crude bromo-toluene and Na. It is also one of the products of the passage of a mixture of benzene and toluene through a red-hot tube (Carnelley, *C. J.* 37, 707; 47, 687). Oxidised by CrO_3 and HOAc to *o*-tolyl-*p*-benzoic acid [180°] and terephthalic acid.

Ditolyls have also been obtained by Barbier (*C. R.* 78, 1769) and Varet a. Vienne, *B.* [2] 47, 919).

References.—DI-AMIDO-, DI-BROMO-, DI-iodo-, NITRO-AMIDO-, OXY-AMIDO-, and OXY-DITOLYL.

p-TOLYL-ACETAMIDINE $\text{C}_6\text{H}_4\text{N}_2$ i.e.

$\text{CH}_2\text{C}(\text{NH})\text{NH.C}_6\text{H}_4\text{Me}$ [1:4]. [96°]. Formed from *p*-toluidine hydrochloride and acetonitrile (Berntsen a. Trompeter, *B.* 11, 1757). Prisms. Alkaline in reaction.— $\text{B}'_2\text{H}_2\text{PtCl}_4$.— $\text{B}'\text{H}_2\text{C}_2\text{O}_4$. Prisms, v. sol. water and alcohol.

Di-o-tolyl-acetamidine

[1:2] $\text{C}_6\text{H}_4\text{Me.NH.CMe:NC}_6\text{H}_4\text{Me}$ [1:2]. [136°] (W.); [140°] (L.). Formed by the action of PCl_5 on *o*-toluidine and HOAc (Ladenburg, *B.* 10, 1262), and also by the action of *o*-toluidine on $\text{CMe}(\text{SEt})\text{NC}_6\text{H}_4$, or on $\text{CMeCl.NC}_6\text{H}_4$ (Wallach a. Wüsten, *B.* 16, 148; *A.* 214, 208). Needles.

Di-p-tolyl-acetamidine

[1:4] $\text{C}_6\text{H}_4\text{Me.NH.CMe:N.C}_6\text{H}_4\text{Me}$ [1:4]. *Acet-tolyl-imid-tolyl-amide*. [120°]. Formed from *p*-toluidine and $\text{CMeCl.NC}_6\text{H}_4$, which is the product of the action of PCl_5 on acetyl-*p*-toluidine (Wallach a. Fassbender, *A.* 214, 203; *B.* 9, 1214; 16, 148). Formed also from *p*-toluidine and bromopropionic acid (Mabery a. Krause, *B.* 22, 8307). Prisms (from benzene). Formed also from *p*-toluidine, HOAc , and PCl_5 .— $\text{B}'_2\text{H}_2\text{PtCl}_4$.— $\text{B}'\text{HCl}$. [200°].

op-Di-tolyl-acetamidine

$\text{C}_6\text{H}_4\text{Me.NH.CMe:NC}_6\text{H}_4\text{Me}$. [142°]. Formed from *o*-toluidine and the product of the action of PCl_5 on acetyl-*p*-toluidine, and also from

p-toluidine and the product of the action of PCl_5 on acetyl-*o*-toluidine (Wallach a. Pannes, *A.* 214, 209). Formed also from *p*-toluidine and $[1:2] \text{C}_6\text{H}_4\text{MeN:CMc.SEt}$, and from *o*-toluidine and $[1:4] \text{C}_6\text{H}_4\text{MeN:CMcSEt}$; the compounds obtained, $[148^\circ]$ and $[140^\circ]$ respectively, being perhaps isomeric and not identical (Wallach, *B.* 16, 148).

***o*-TOLYL-ACETIC ACID** $\text{C}_8\text{H}_9\text{O}_2$ *i.e.*

$[1:2] \text{C}_6\text{H}_4\text{Me.CH}_2\text{CO}_2\text{H}$. $[89^\circ]$. Formed by saponification of its nitrile (Radziszewski a. Wispeck, *B.* 15, 1747; 18, 1281). Needles, sl. sol. cold water. Yields phthalic acid on oxidation.— CaA' , 4aq.— AgA' . Plates, sol. hot water.

Amide $[161^\circ]$. Plates, sl. sol. ether.

Nitrile $\text{C}_8\text{H}_7\text{N}$. (244°) . S.G. d_4^{25} 1.0156. Formed from ω -bromo-*o*-xylene and KCy . Oil.

m-Tolyl-acetic acid $[1:3] \text{C}_6\text{H}_4\text{Me.CH}_2\text{CO}_2\text{H}$. $[61^\circ]$. Formed by saponifying its nitrile, which is obtained from ω -bromo-*m*-xylene (R. a. W.). Needles, sol. hot water.— CaA' , 3aq.— AgA' .

Amide $[141^\circ]$. Sl. sol. cold water.

Nitrile (241°) . S.G. d_4^{25} 1.0022. Oil.

Methyl ether MeA' . (238°) . S.G. d_4^{25} 1.044. Liquid (Senkowski, *M.* 9, 854).

Ethyl ether EtA' . (238°) . S.G. d_4^{25} 1.018.

p-Tolyl-acetic acid $[1:4] \text{C}_6\text{H}_4\text{Me.CH}_2\text{CO}_2\text{H}$. $[94^\circ]$. Formed in like manner from ω -bromo-*p*-xylene (R. a. W.; Strassmann, *B.* 22, 1230). Got also by reducing *p*-tolyl-glyoxylic acid with HI (Claus a. Kroseberg, *B.* 20, 2051). Needles, sl. sol. cold water. Phthalic anhydride and

NaOAc yield $\text{C}_6\text{H}_4\text{C}(\text{CO})\text{C}(\text{CH}_2\text{C}_6\text{H}_4\text{Me})\text{O}$ $[151^\circ]$, whence HNO_2 at 0° forms the compound

$\text{C}_6\text{H}_4\text{C}(\text{CO})\text{C}(\text{NO}_2)\text{CH}(\text{NO}_2)\text{C}_6\text{H}_4\text{O}$ $[140^\circ]$, which is converted by treatment with boiling alcohol into

$\text{C}_6\text{H}_4\text{C}(\text{CO})\text{C}(\text{CNO}_2)\text{C}_6\text{H}_4\text{O}$ $[207^\circ]$, and is reduced

by HI and P to $\text{C}_6\text{H}_4\text{C}(\text{CH}_2\text{C}_6\text{H}_4\text{Me})\text{O}$ $[116^\circ]$ (Ruhemann, *B.* 24, 3965).— NaA' : needles, sol. water.— CaA' , 8aq.— AgA' : needles, sol. hot water.

Ethyl ether EtA' . (240°) .

Amide $\text{C}_8\text{H}_9\text{NO}$. $[185^\circ]$. Plates. Formed from the acid, and also by the action of yellow ammonium sulphide on *p*-tolyl methyl ketone (Willgerodt, *B.* 21, 534).

Nitrile $\text{C}_8\text{H}_7\text{CN}$. $[18^\circ]$. (243°) . S.G. d_4^{25} 1.0922.

Reference.—*Nitro-* and *Oxy-TOLYL-ACETIC ACID*.

***m*-TOLYL-ACETYLENE** $[1:3] \text{C}_6\text{H}_4\text{Me.C}\equiv\text{CH}$. *Methyl-styrene*. (164°) . Formed by distilling barium *m*-tolyl-propionate with lime (Müller, *B.* 20, 1215). Formed also by saturating a solution of *m*-tolyl-acrylic acid with HBr at 0° and treating the product with NaOH aq. Oil, becoming solid on standing. Gives an explosive red pp. with ammoniacal Cu_2Cl_2 . Br forms $\text{C}_6\text{H}_4\text{CHBr.CH}_2\text{Br}$ $[45^\circ]$.

Di-tolyl-acetylene $\text{C}_6\text{H}_4\text{C}\equiv\text{CC}_6\text{H}_4$. $[136^\circ]$. Formed by heating $\text{C}_6\text{H}_4\text{CHBr.CHBr.C}_6\text{H}_4$ with alcoholic potash at 140° (Goldschmiedt a. Hepp, *B.* 6, 1505). Needles (from alcohol).

DI-TOLYL-ACIPERAZINE v. **OXY-DI-TOLYL-PYRAZINE**.

Di-tolyl-di-*ac*-piperazine v. **Di**-oxy-di-tolyl-pyrazine.

***m*-TOLYL-ACRYLIC ACID** $\text{C}_9\text{H}_9\text{O}_2$ *i.e.*

$[1:3] \text{C}_6\text{H}_4\text{Me.CH:CH.CO}_2\text{H}$. *Methyl-cinnamic acid*. $[111^\circ]$. Formed by heating *m*-toluic aldehyde with Ac_2O and NaOAc (Bornemann, *B.* 17, 1474; 20, 1382; Von Miller, *B.* 20, 1213; 23, 1899). Silky needles, v. sol. alcohol, sl. sol. ligroin. FeCl_3 gives a bright-yellow pp. in neutral solutions. Reduced by sodium-amalgam to *m*-tolyl-propionic acid $[48^\circ]$. KMnO_4 oxidises it to *m*-toluic acid. Br forms $\text{C}_6\text{H}_4\text{C}_2\text{H}_4\text{Br}_2\text{CO}_2\text{H}$ $[167^\circ]$.— BaA' — AgA' . Crystalline powder.

***p*-Tolyl-acrylic acid**

$[1:4] \text{C}_6\text{H}_4\text{Me.CH:CH.CO}_2\text{H}$. $[197^\circ]$. Formed from *p*-toluic aldehyde, NaOAc , and Ac_2O (Von Miller, *B.* 23, 1897; cf. Kröber, *B.* 23, 1033). Needles (from benzene), sl. sol. hot water. Reduced by HI and P to *p*-tolyl-propionic acid. Br forms $\text{C}_6\text{H}_4\text{Me.CHBr.CHBr.CO}_2\text{H}$.

TOLYL ALCOHOL v. **TOLYL-CARBINOL**.

***p*-TOLYL-ALLYL-HYDRAZINE** $\text{C}_{10}\text{H}_{11}\text{N}_2$ *i.e.*

$\text{C}_6\text{H}_4\text{N}(\text{C}_6\text{H}_5)\text{NH}_2$. $(160^\circ\text{--}170^\circ)$ at 90 mm.). Got from tolyl-hydrazine and allyl bromide (Michaelis, *B.* 26, 2178). Oil. Yields B'HC . $[129^\circ]$. Benzoic aldehyde forms the compound $\text{C}_6\text{H}_4\text{N}(\text{C}_6\text{H}_5)\text{N:OHP}$ $[61^\circ]$, while cinnamic aldehyde forms the corresponding hydrazide $[118^\circ]$. Ferric chloride gives the tetrazone $(\text{C}_6\text{H}_4(\text{C}_6\text{H}_5\text{N})\text{N}_2$ $[104^\circ]$.

***o*-TOLYL-ALLYL-THIO-SEMI-CARBAZIDE**

$\text{C}_6\text{H}_4\text{NH.NH.CS.NHC}_6\text{H}_5$. $[105^\circ]$. Formed by warming *o*-tolyl-hydrazine with allyl thiocarbimide (Avenarius, *B.* 24, 268). Needles, insol. water, v. sol. alcohol and CS_2 .

***p*-Tolyl - thio - semi - carbazide** $[128^\circ]$. Formed in like manner (A.). Needles.

***o*-TOLYL-ALLYL-THIO-UREA** $\text{C}_{11}\text{H}_{11}\text{N}_2\text{S}$ *i.e.*

$\text{C}_6\text{H}_4\text{NH.CS.NHC}_6\text{H}_5$. *Tolyl-thiosinamins*. $[98^\circ]$. Formed from *o*-toluidine and oil of mustard (Jailard, *Z.* 1865, 441; Maly, *Z.* [2] 5, 258; Weith, *B.* 8, 1528; Prager, *B.* 22, 2998). Pearly crystals, m. sol. ether, v. sol. HOAc . According to Dixon (*C. J.* 55, 622), it melts at 76° . Converted by heating with HCl aq into tolyl-propylene- ψ -thio-urea $[126^\circ]$. Cyanogen passed into its alcoholic solution forms $\text{C}_6\text{H}_4\text{N}_2\text{S}$, which on warming with dilute H_2SO_4 and alcohol gives a pp. of oxalyl-tolyl-allyl-thio-urea $\text{CS}(\text{NC}_6\text{H}_4)_2\text{O}_2$ $[157^\circ]$.

Reference.—**OXY-TOLYL-ALLYL-THIO-UREA**.

***o*-TOLYL-AMIDO-ACETIC ACID** $\text{C}_8\text{H}_9\text{NO}_2$

i.e. $\text{C}_6\text{H}_4\text{Me.NH.CH}_2\text{CO}_2\text{H}$. *Tolyl - glyccoll*. $[150^\circ]$. Prepared by the action of chloro-acetic acid and aqueous NaOAc on *o*-toluidine (Staats, *B.* 18, 187; Cosack, *B.* 13, 1091; Ehrlich, *B.* 16, 204; Bischoff a. Nastvogel, *B.* 22, 1787).— CuA' , 2aq. Small needles.— CaA' , 8aq: needles, m. sol. water (Mauthner, *M.* 11, 377).

Ethyl ether EtA' . (281°) . S.G. d_4^{25} 1.058. Oil (Bischoff, *B.* 25, 2270).

Acetyl derivative $\text{C}_8\text{H}_7\text{NAc.CH}_2\text{CO}_2\text{H}$. $[212^\circ]$. Tables (from dilute alcohol).

Chloro-acetyl derivative

$\text{C}_6\text{H}_4\text{N}(\text{CO.CH}_2\text{Cl}).\text{CH}_2\text{CO}_2\text{H}$. $[117^\circ]$. Formed from the acid and chloro-acetyl chloride in ether (Widman, *J. pr.* [2] 88, 804). Rectangular plates, v. sol. hot alcohol, sl. sol. water.

Bromo-acetyl derivative

$\text{C}_6\text{H}_4\text{N}(\text{CO.CH}_2\text{Br}).\text{CH}_2\text{CO}_2\text{H}$. $[124^\circ]$. Rectangular plates.

Glycolyl derivative

$C_6H_5N(CO.CH_2.OH).CH_2.CO_2H$. [144°]. Formed by boiling the chloro-acetyl derivative with conc. Na_2CO_3 aq (Abenius, *J. pr.* [2] 40, 503). V. e. sol. water. Yields KA' aq, BaA' 7aq, and AgA' , and is converted by heating at 160° into $C_6H_5N<\frac{CO.CH_2}{CH_2.CO}>O$ [109°], whence alcoholic NH_3 produces $C_6H_5N(CO.CH_2.OH).CH_2.CO.NH_2$ [152°], crystallising in plates (from alcohol).

o-Toluide $C_6H_4NH.CH_2.CO.NHC_6H_5$. [92°]. Formed by boiling chloro-acetic ether with *o*-toluidine (Ehrlich, *B.* 16, 205). Needles, insol. water and HCl aq.

m-Tolyl-amido-acetic acid

[1:3] $C_6H_4Me.NH.CH_2.CO_2H$. Formed from chloro-acetic acid and *m*-toluidine in ether (Ehrlich, *B.* 15, 2011). Solid mass.— CuA' 2aq.

Ethyl ether EtA' . [68°]. Formed from chloro-acetic ether and *m*-toluidine. Six-sided plates, v. sol. alcohol and ether, sl. sol. Aq.

p-Tolyl-amido-acetic acid

[1:4] $C_6H_4Me.NH.CH_2.CO_2H$. [119°]. Formed, together with a compound [168°], from *p*-toluidine chloro-acetic acid and $NaOAc$ (dissolved in a little water) at 100° (P. J. Meyer, *B.* 8, 1158; 14, 1323; Staats, *B.* 13, 137; Schwebel, *B.* 10, 2047; Bischoff, *B.* 23, 1997; 25, 2281). Got also by saponifying its ether. Needles (from water). When fused with potash it yields a product which, when dissolved in water, is oxidised by air to an indigo-derivative (Heumann, *B.* 24, 1346). When fused with *p*-chloro-acet-toluide it yields methyl-indigo (Eckenroth, *B.* 24, 693). The compound [168°], formerly supposed to be *p*-tolyl-amido-acetic acid, ought, according to Bischoff a. Hausdörfer (*B.* 25, 2281) to be represented as $CO_2H.CH_2.N(C_6H_5).CH_2.CO.ONH_2.C_6H_5$.

Ethyl ether EtA' . [49°]. Formed from chloro-acetic ether and *p*-toluidine. Monoclinic plates, v. sl. sol. hot water.

Amide $C_6H_5N_2O$. [163°]. Formed by heating *p*-toluidine with chloro-acetamide. Plates, v. sl. sol. cold water.

Anilide $C_6H_5NH.CH_2.CO.NHPh$. [83°]. Formed by heating chloro-acetic acid with aniline. Needles (from hot water).

p-Toluide $C_6H_4NH.CH_2.CO.NC_6H_5$. [136°]. Formed in like manner, and also by heating toluidine with the compound of glyoxal with $NaHSO_3$ (Hinsberg, *B.* 21, 112). Plates, v. sl. sol. hot water. Yields a chloro-acetyl derivative [158°].

Nitrile $C_6H_5NH.CH_2.CN$. [126°]. A product of the action of heat on the amide.

Acetyl derivative $C_6H_5Nac.CH_2.CO_2H$. [175°]. Formed from chloro-acetic ether and C_6H_5NacNa , the product being saponified with potash (Paal a. Otten, *B.* 23, 2596). Plates (from water).— NaA' 3aq: plates, v. sol. water.

Imide $(C_6H_5NH.CH_2.CO)_2NH$. [210°]. Got by heating the acid at 200° and adding NH_3 aq to the product. Needles, sl. sol. water and NH_3 aq (Bischoff).

Di-o-tolyl-di-amido-acetic acid $(C_6H_4NH).CH.CO_2H$. [240°]. Formed by heating di-chloro acetic acid with *o*-toluidine (P. Meyer, *B.* 16, 925). Needles, insol. water, sl. sol. alcohol, v. sol. aqueous acids and alkalis.

Reference.—NITRO-TOLYL-AMIDO-ACETIC ACID.

p-TOLYL-AMIDO-ACETOPHENONE

[1:4] $C_6H_4Me.NH.CH_2.CO.C_6H_5$. *Phenacyl-p-toluidine*. [184°]. Formed from *p*-toluidine and bromo-acetophenone in alcohol (Lellmann a. Donner, *B.* 23, 167). Tables, v. sol. benzene, m. sol. alcohol. Yields, on nitration, [1:3:4] $C_6H_4Me(NO_2).NH.CH_2.Bz$ [165°] and a di-nitro-derivative [156°]. Forms $B'HNO_3$ and $B'HCi$.

p-TOLYL-AMIDO-ACRYLIC ETHER

[1:4] $C_6H_4Me.NH.CH_2.CH.CO_2Et$. [116°]. Formed from *p*-toluidine and formyl-acetic ether (Von Pechmann, *B.* 25, 1053). Yellow plates, insol. water and ligroin. Alcoholic potash yields plates [144°]. Ac_2O forms acetyl-toluidine.

TRI-p-TOLYL-TRI-AMIDO-BENZENE

$C_{27}H_{21}N_3$, i.e. $C_6H_5(NHC_6H_4)_3$. [187°]. Formed by heating phloroglucin with *p*-toluidine at 210° (Minunni, *B.* 21, 1984). Needles, v. sl. sol. cold alcohol. Conc. H_2SO_4 forms a bluish-green solution, turning black on heating.— $B''HCl$: amorphous; decomposed by water.— $B''2HCl$: small needles.— $B''H_2PtCl_6$.

Tri-acetyl derivative [193°]. Plates.

Tri-benzoyl derivative [282°]. Minute prisms.

p-TOLYL-AMIDO-BENZOYL-(a)-NAPHTHO-QUINONE

$C_6H_5.CO.C_6H_4<\frac{CO.C_6H_4NHC_6H_5}{CO.CH}$. [197°]. Formed by boiling *p*-toluidine with benzoyl-(a)-naphthoquinone in alcoholic solution for 15 minutes (Kegel, *A.* 247, 185). Red needles (from $HOAc$), v. sl. sol. alcohol.

p-TOLYL-o-AMIDO-BENZYL-AMINE

[4:1] $C_6H_4Me.NH.CH_2.C_6H_4NH_2$ [1:2]. [80-5°]. Got by reducing *p*-tolyl-o-nitro-benzyl-amine (Söderbaum a. Widman, *B.* 23, 2187). Thin leaflets (from alcohol). Ac_2O yields a di-acetyl derivative [186°]. The mono-acetyl derivative $C_6H_5Nac.CH_2.C_6H_4NH_2$ [99°] may be got by reducing $C_6H_5Nac.CH_2.C_6H_4NO_2$.

o-TOLYL-α-AMIDO-*n*-BUTYRIC ACID

$C_6H_5NH.CHEt.CO_2H$. [84°]. Long prisms. Forms an acetyl derivative [116°] and yields propyl-*p*-toluidine on distillation.

Ethyl ether EtA' . (278°). S.G. $\frac{20}{4}$ 1.019. Got by heating *p*-toluidine with α-bromo-butyric ether at 100° (Bischoff a. Mintz, *B.* 25, 2314).

o-Tolyl-α-amido-isobutyric acid

$C_6H_5NH.CMe.CO_2H$. [62°]. Formed together with the β-isomeride [110°] by the action of KOH and a current of steam on the ether [57°], which is got by heating *p*-toluidine with α-bromo-isobutyric ether (Bischoff a. Mintz, *B.* 25, 2334). The acid [110°] yields an acetyl derivative [219°], sl. sol. ether. On distillation it forms a lactone [95°].

p-Tolyl-α-amido-*n*-butyric acid

$C_6H_5NH.CHEt.CO_2H$. [153-156°]. Got from the ether EtA' (279°) S.G. $\frac{20}{4}$ 1.011, which is produced when *p*-toluidine is heated with α-bromo-*n*-butyric acid at 105°. Leaflets. Yields propyl-*p*-toluidine on distillation.

Acetyl derivative $C_6H_5Nac.CHEt.CO_2H$. [149°].

p-Tolyl-α-amido-isobutyric acid

[1:4] $C_6H_4Me.NH.CMe.CO_2H$. [150°]. Formed, together with the β-isomeride, by the action of hot potash in a current of steam on the ether EtA' [36°], which is got by heating *p*-toluidine with α-bromo-isobutyric acid. Yields an acetyl

derivative [146°]. Forms isopropyl-*p*-toluidine on distillation.

p-Tolyl- β -amido-isobutyric acid $C_6H_4NH.CH_2.CHMe.CO_2H$. [196°]. Formed as above. Gives an acetyl derivative [206°] and decomposes on distillation into *p*-toluidine and a lactone $C_6H_4N<\frac{CH_2.CHMe}{CO.CMe_2.O}>CO$ (?) [170°].

***o*-TOLYL-AMIDO-CROTONIC ACID**

[1:2] $C_6H_4Me.NH.CMe:CH.CO_2H$. *Methyl ether* MeA'. [31°]. Formed by the action of *o*-toluidine on methyl aceto-acetate (Conrad a. Limpach, B. 21, 523). Prisms (from alcohol).

Ethyl ether EtA'. Yellowish oil.

p-Tolyl-amido-crotonic acid.

Methyl ether MeA'. [60°]. Prisms.

Ethyl ether EtA'. [29°]. Formed from acetoacetic ether and *p*-toluidine.

TOLYL-AMIDO-CYANURIC ACID v.

Cyanuric acid, described under CYANIC ACIDS.

***p*-TOLYL-AMIDO-METHENYL-BENZAMID-**

OXIM CPh $\langle \frac{N.O}{N} \rangle C.NH.C_6H_4Me$ [1:4]. [135°].

Formed by heating *p*-tolyl-thiocarbimide with benzamidoxim (Koch, B. 24, 398). Plates (from alcohol), v. sol. ether.

**DI-*p*-TOLYL-AMIDO-METHYLENE-*o*-PHE-
NYLENE DIAMINE** $C_{21}H_{22}N_4$, i.e.

$C_6H_4 \langle \frac{NH}{NH} \rangle C \langle \frac{NH.C_6H_4}{NH.C_6H_4} \rangle$. [186°]. (above 400°).

Formed by heating $C(NC_6H_4)_2$ with *o*-phenylenediamine at 135° (Moore, B. 22, 1639; 3188). Tables (from alcohol), v. sl. sol. boiling water. —Salts: B' $\cdot 3HCl$. Needles. —B' $\cdot 3H_2PtCl_6$ 8aq. —B' $\cdot H_2SO_4$. Needles, insol. ether, v. sol. hot Aq.

Nitrosamine

$C_6H_4 \langle \frac{N(NO)}{N(NO)} \rangle C(NC_6H_4.NO)_2$. [130°]. Yellow needles, v. sol. alcohol.

Di-acetyl derivative [143°]. Needles.

Di-benzoyl derivative [185°]. Prisms.

Tetra-benzoyl derivative [274°].

Tetra-*p*-tolyl-tetra-amido - di - methylene - *o*-phenylene-diamine $C_{24}H_{26}N_4(C(NHC_6H_4)_2)_2$.

[116°]. Formed by heating $C(NC_6H_4)_2$ with *o*-phenylenediamine at 200° (Moore, B. 22, 3195). Needles, v. sol. alcohol. Decomposed by dilute $HClAq$ at 150° into di-*p*-tolyl-urea and *o*-phenylenediamine. —B' $\cdot 2H_2SO_4$. Needles, sl. sol. cold water. —B' $\cdot 3HCl$. —B' $\cdot 3H_2PtCl_6$ 15aq.

Tetra-acetyl derivative [115°].

Tetra-benzoyl derivative [146°].

**DI-*p*-TOLYL-AMIDO - METHYLENE-*o*-PHE-
NYLENE-PHENYL-GUANIDINE**

$C_6H_4 \langle \frac{N}{N} \rangle C.NPh \rangle C(NHC_6H_4)_2$ [187°]. Formed

by boiling $C(NC_6H_4)_2$ with *o*-phenylene-phenyl-guanidine (Keller, B. 24, 2508). Needles (from boiling alcohol), sl. sol. ether.

**DI - *p* - TOLYL - AMIDO - METHYLENE - *o* -
PHENYLENE-*p*-TOLYL-GUANIDINE**

$C_6H_4.N_2(CNC_6H_4):C(NHC_6H_4)_2$. [188°]. Formed by heating *o*-phenylene-*p*-tolyl-guanidine with $C(NC_6H_4)_2$ at 220° (Keller, B. 24, 2513). Prisms (from benzene).

**DI - *p* - TOLYL - AMIDO - METHYLENE - *o* -
TOLYLENE-*p*-TOLYL-GUANIDINE**

$C_6H_4.N_2(C:NC_6H_4):C(NHC_6H_4)_2$. [210°]. Formed by heating tolylene-*p*-tolyl-guanidine together

with $C(NC_6H_4)_2$ at 220° (Keller, B. 24, 2521). Needles, sl. sol. alcohol.

***o*-TOLYL-AMIDO - METHYL - MALONAMIC
ETHER** $CO_2Et.CMe(NHC_6H_4).CO.NH_2$. Formed by dissolving α -cyano-tolyl- α -amido-propionic ether in conc. H_2SO_4 (Gerson, B. 19, 2966). Long needles, sol. hot water. Converted by boiling $NaOHAq$ into tolyl-amido-propionic acid.

***p*-TOLYL-AMIDO-*p*-METHYL-OXINDOLE**

$C_{16}H_{16}N_2O$ i.e. $C_6H_4Me \langle \frac{NH}{CH(NHC_6H_4)} \rangle CO$.

[167°]. Formed by heating di-chloro- (or di-bromo-) acetic acid with *p*-toluidine (Duisberg, B. 18, 190). Needles, v. sol. hot alcohol. Reduces ammoniacal $AgNO_3$, forming a mirror. Readily absorbs oxygen from the air, forming

$C_6H_4Me \langle \frac{NH}{C(NC_6H_4)} \rangle CO$. Alcoholic KOH forms a blood-red solution. —B' HCl : crystalline powder.

Di-acetyl derivative $C_{16}H_{14}Ac_2N_2O$. [147°].

Nitrosamine $C_{16}H_{16}N_2O_2$. [c. 220°].

***p*-TOLYL-AMIDO-METHYL-THIAZOLE**

$S \langle \frac{CH=CMe}{C(NHC_6H_4):N} \rangle$. [125°]. Formed from oxy-methyl-thiazole and *p*-toluidine (Hantzsch a. Weber, B. 20, 3130).

TRI-*p*-TOLYL-AMIDO-NAPHTHALENE

$C_6H_4 \langle \frac{C(NHC_6H_4):C(NHC_6H_4)}{C(NHC_6H_4):CH} \rangle$. [160°]. Formed

by heating nitroso-ethyl-(α)-naphthylamine with *p*-toluidine at 150° (Fischer a. Hepp, A. 256, 244). Needles (from alcohol). Readily oxidised to di-methyl-phenyl-rosinduline.

***o*-TOLYL-AMIDO - (α) - NAPHTHOQUINONE**

$C_{11}H_9NO_2$ i.e. $C_{10}H_7O_2(NHC_6H_4)$. [142°]. Formed from *o*-toluidine and (α)-naphthoquinone (Elsbach, B. 15, 689). Red needles, sol. $NaOHAq$.

***p*-Tolyl-amido-(α)-naphthoquinone**

$C_{15}H_{13}O_2(NHC_6H_4)$. [202°]. Formed from (α)-naphthoquinone and *p*-toluidine in hot alcoholic solution (Plimpton, C. J. 37, 638). Formed also by the action of *p*-toluidine on (β)-oxy-(α)-naphthoquinone, and by heating *p*-tolyl-amido-(β)-naphthoquinone with $HOAc$ at 150° (Elsbach, B. 15, 687). Red needles. Forms a crimson solution in conc. H_2SO_4 . Insol. $NaOHAq$.

Ditoluide $C_6H_4 \langle \frac{C(NC_6H_4):C.NHC_6H_4}{C(NC_6H_4):CH} \rangle$.

[147°]. Formed by oxidation of tri-*p*-tolyl-amido-naphthalene (Fischer a. Hepp, A. 256, 246). Orange plates.

***o*-Tolyl-amido-(β)-naphthoquinone**

$C_{11}H_9O_2(NHC_6H_4)$ or $C_{10}H_7(OH)O(NC_6H_4)$. [240°]. Formed from (β)-naphthoquinone and *o*-toluidine (Elsbach, B. 15, 689). Red needles, sol. dilute $NaOHAq$. Not affected by heating with $HOAc$ at 150°. On heating with dilute $HClAq$ it yields (β)-oxy-(α)-naphthoquinone and *o*-toluidine.

***p* - TOLYL - AMIDO - (β) - NAPHTHOQUINONE** [246°].

Formed from (β)-naphthoquinone and *p*-toluidine (Elsbach, B. 15, 686). Red needles, sol. hot alcohol and $NaOHAq$. On heating with $HClAq$ at 180° it is split up into *p*-toluidine and (β)-naphthoquinone.

Methyl ether MeA'. [150°]. Red crystals (Zincke a. Brauns, B. 15, 1969).

Ethyl ether EtA'. [187°].

Isopropyl ether PrA'. [139°].

p-Toluide $C_7H_7(NHC_2H_5)O(NC_2H_5)$. [188° cor.]. Formed by heating di-bromo-(α)-naphthol with *p*-toluidine (Meldola, *C. J.* 45, 159). Formed also from (β)-naphthoquinone oxim, *p*-toluidine, and HOAc (Bromme, *B.* 21, 391). Orange crystals with green lustre.

DI-*o*-TOLYL-DI-AMIDO-OLIAZTHIOLE

$C_{16}H_{16}N_4S$ i.e. $S \begin{smallmatrix} \diagup C(NHC_2H_5)_2 \\ \diagdown C(NHC_2H_5)_2 \end{smallmatrix} N$. [185°]. Formed by boiling an alcoholic solution of *o*-tolyl-thio-urea with dilute HClAq and H_2O_2 (Hector, *B.* 23, 368). V. sol. alcohol. Cyanogen passed into its alcoholic solution forms $C_{16}H_{16}N_4SO_2$ [89°].— $B'HClAq$. [219°].— $B'_2H_2PtCl_3$. [192°].— $B'AgNO_3$. White pp.— $B'_2H_2HgCl_2$. [232°]. Needles.—Picrate: $B'C_6H_5N_3O_7$. [201°].

Acetyl derivative $C_{16}H_{14}AcN_4S$. [221°].

Benzoyl derivative $C_{16}H_{12}BzN_4S$. [214°].

Nitrosamine $C_{16}H_{13}(NO)N_4S$. [135°].

Di-*p*-tolyl-di-amido-oliazthiole $C_{16}H_{16}N_4S$. [127°]. Formed in like manner from *p*-tolyl-thio-urea (Hector, *B.* 23, 364). Thick yellowish prisms, v. sol. alcohol. Cyanogen forms $B'Cy_2$ [190°].— $B'HCl$. [233°]. White needles, becoming reddish in air.— $B'_2H_2PtCl_3$ 1½ aq. [109°].— $B'AgNO_3$ 1½ aq. [177°].— $B'_2H_2HgCl_2$. [114°–119°].—Picrate [238°]. Yellow prisms, sl. sol. alcohol.

Acetyl derivative $C_{16}H_{14}AcN_4S$. [166°].

Benzoyl derivative $C_{16}H_{12}BzN_4S$. [186°].

Nitrosamine $C_{16}H_{13}(NO)N_4S$. [247°].

***o*-TOLYL-*m*-AMIDO-PHENOL** C_8H_7NO i.e. $C_6H_4NH.C_6H_4.OH$. (c. 373° cor.). Formed from resorcin, *o*-toluidine, and $CaCl_2$ at 270° (Philip, *J. pr.* [2] 34, 70). Oil. Reduced by hot zinc-dust to hydro-acridine and acridine.

Formyl derivative. [169°]. Tables.

***o*-Tolyl-*p*-amido-phenol** $C_8H_7NH.C_6H_4.OH$. [90°]. (367° cor.). Formed from hydroquinone, *o*-toluidine and $CaCl_2$ at 240° (Philip, *J. pr.* [2] 84, 57). White laminae (from light petroleum). Reduced by distilling with zinc to hydro-acridine and acridine. Converted by heating with conc. HCl into hydroquinone and *o*-toluidine.

Salt.— $B'HCl$: crystalline powder.

Mono-formyl derivative [136–5°].

Di-acetyl derivative [106°]: needles.

Di-benzoyl derivative. [171°].

***p*-tolyl-*m*-amido-phenol** C_8H_7NO i.e. $C_6H_4.NH.C_6H_4.OH$. [92°]. (350° cor.). From resorcin, *p*-toluidine and $CaCl_2$ at 260° for 8 hours (Hatschek a. Zega, *J. pr.* [2] 83, 209). Prisms or needles (from benzene mixed with petroleum ether). Distilled over zinc-dust, it gives C_6H_5NHPh .

Salts.— $B'HCl$; decomposed by water.

Formyl derivative.—

$C_8H_7.N(CHO).C_6H_4.OH$. [146°]. V. sol. ether.

Di-benzoyl derivative.—

$C_8H_7.NBzC_6H_4.OBz$. [c. 105°]. Gives with fuming HNO_3 a di-nitro-derivative, [116°].

Nitrosamine.— $C_8H_7.N(NO).C_6H_4.OH$. *Oxy-phenyl-tolyl-nitrosamine*. [105°]. Yellow needles (from dil. alcohol).

***p*-Tolyl-*p*-amido-phenol** $C_8H_7NH.C_6H_4.OH$. [122°]. (350°–360°). From hydroquinone, *p*-toluidine, and $CaCl_2$ 8 hours at 260° (Hatschek a. Zega, *J. pr.* [2] 83, 224). Plates. Heated with zinc-dust it gives phenyl-*p*-tolyl-amine.

Salt.— $B'HCl$. Powder, decomposed by Aq.

Di-acetyl derivative. [101°]. Tables.

Di-benzoyl derivative. [169°].

Nitroso-derivative $C_8H_7.N(NO).C_6H_4.OH$ [130°]; needles. Very unstable.

***o*-TOLYL- α -AMIDO-PHENYL-ACETIC ACID** $NHC_2H_5.CHPh.CO_2H$. [143°]. Formed from α -bromo-phenyl-acetic acid and *o*-toluidine (Stöckenius, *J.* 1878, 781). Plates, almost insol. water.

***p*-Tolyl- α -amido-phenyl-acetic acid**. Formed in like manner, using *p*-toluidine. Insol. water.

Ethyl ether EtA'. [90°]. Yellowish prisms.

***o*-TOLYL-AMIDO-TRI-PHENYL-METHANE** $CPh_3.NHC_2H_5$. [142°]. Formed from CPh_3Br and *o*-toluidine (Wittich, *B.* 17, 705). Prisms (from ether).

***p*-Tolyl-amido-tri-phenyl-methane** [177°]. Crystals (from ether).

Nitrosamine $CPh_3.NC_2H_5.NO$. [145°–148°].

***p*-TOLYL-AMIDO-DI-PHENYL-NAPHTHO-**

QUINOXALINE. Phenyl-o-chloride

$C_6H_4 \begin{smallmatrix} \diagup C(NH.C_6H_4.Me) \\ \diagdown C.N=O \end{smallmatrix} CPh$

Got by heating $C_{10}H_7(OEt) \begin{smallmatrix} \diagup N=O \\ \diagdown NPhCl \end{smallmatrix} CPh$ with *p*-toluidine at 120° (Witt a. Schmidt, *B.* 25, 2005). Bronzed plates, v. sol. alcohol, forming a crimson solution. Conc. H_2SO_4 forms a slate-blue solution, becoming first blue and then violet on dilution.

TRI-*p*-TOLYL-TRI-AMIDO-DI-PHENYL-

TOLYL-CARBINOL $C_{14}H_{13}N_3O$. *Tri-tolyl-rosaniline*. The salts are formed by heating rosaniline salts with *p*-toluidine (Hofmann, *A.* 132, 290).— $C_{14}H_{13}N_3Cl$. Small blue crystals (from alcohol), insol. water.

TOLYL-AMIDO-PIPIITZAHIC ACID *c.* *Toluidio-PIPIITZAHIC ACID*.

***o*-TOLYL- α -AMIDO-PROPIONIC ACID**

$CH_3.CH(NHC_2H_5).CO_2H$. [116°]. Formed by saponification of the nitrile (Tiemann a. Stephan, *B.* 15, 2038; *C. C.* 1886, 470). Got also by boiling *o*-tolyl-amido-methyl-malonic acid with $NaOH$ Aq (Gerson, *B.* 19, 2963). White crystals.

Ethyl ether EtA' (278°). S.G. $\frac{2}{3}$ 1.047. Formed from α -bromo-propionic ether and *o*-toluidine (Bischoff a. Hausdörfer, *B.* 25, 2298).

Acetyl derivative $C_8H_7.NAc.CHMe.CO_2H$. [177°]. Leaflets.

Amide. [125°]. Minute needles.

Nitrile $CH_3.CH(NHC_2H_5).CN$. [73°]. Formed by digesting the cyanhydrin of acetic aldehyde (lactonitrile) with *o*-toluidine.

***p*-Tolyl- α -amido-propionic acid**. [158°]. Formed in like manner. Plates, sl. sol. water and ether. May be sublimed.

Ethyl ether EtA'. [85°]. Tables.

Acetyl derivative [166°].

Amide. [145°]. Needles, sol. hot Aq.

Nitrile. [82°]. Plates, sl. sol. hot Aq.

***p*-Tolyl- β -amido-propionic acid**

$C_6H_5.Me.NH.CH_2.CH_2.CO_2H$. [86°]. Formed from β -iodo propionic acid and *p*-toluidine (Bischoff a. Mintz, *B.* 25, 2352). Pearly scales, v. e. sol. ether.

Reference. — DI-BROMO-TOLYL-AMIDO-PROPIONITRILE.

***o*-TOLYL-AMIDO-PYROTARTRIMIDE**

$CH_2.CO \begin{smallmatrix} \diagup NH \\ \diagdown C(NHC_2H_5).CO \end{smallmatrix}$ [181°]. Obtained by saponi-

reaction of *o*-tolyl-amido-pyrotartramic ether, which is formed by the action of H_2SO_4 upon the α -cyano- α -*o*-toluidio-butyric ether (Schiller-Wechler, *B.* 18, 1050). White needles. V. sol. alcohol and benzene, sl. sol. ether and hot water, insol. cold water and ligroin. Has both acid and basic properties.

DI-*p*-TOLYL-DI-AMIDO-SUCCINIC ACID

$CO_2H.CH(NHCO_2H).CH(NHCO_2H).CO_2H$. [c. 200°]. Formed, together with 'di-tolil succin', $C_{15}H_{15}N_2O_8$ [228°], by boiling di-bromo-succinic acid with *p*-toluidine (Junghahn a. Reissert, *B.* 26, 1766). V. sol. alcohol, insol. water. Yields a di-nitroso-derivative [125°], and a di-acetyl derivative $C_{22}H_{21}N_2O_9$ aq, which yields CaA'' aq, BaA'' aq, and anhydrides $C_{22}H_{21}N_2O_8$ [232°], and $C_{22}H_{20}N_2O_8$ [222°].— NaA'' .— CaA'' .— CuA'' .
Ethyl ether EtA''. [169°]. Needles.

DI-*p*-TOLYL-TRI-AMIDO-TOLUENE

$C_6H_2Me(NHCO_2H)_3(NH_2)$ [1:2:5:4]. [166°]. Formed by reducing amido-toluquinone ditoluide with zinc-dust and $HOAc$ (Green, *C. J.* 63, 1403; cf. Barsilowsky, *B.* 6, 1209). Plates (from dilute $HOAc$). A very feeble base.

DI-*p*-TOLYL-DI-AMIDO-TOLUQUINONE

$C_6HMeO_2(NHCO_2H)_2$ [1:2:5:4:6]. [178°]. Formed from azotoline, $MeOH$, and conc. H_2SO_4 (Fischer a. Hepp, *A.* 262, 251). Brownish-red needles.

DI-*p*-TOLYL-DI-AMIDO-TOLUQUINONE

$C_6HMeO_2(NHCO_2H)_2$ [1:2:5:3:6]. [241°]. Formed by boiling toluquinone with *p*-toluidine and alcohol (Fischer a. Hepp, *A.* 256, 269). Yellow needles.

DI-*p*-TOLYL-DI-AMIDO-TOLUQUINONE *p*-TOLUIDE
 $C_{28}H_{27}N_3O_8$. [191°]. Claret-red plates (Fischer a. Hepp, *B.* 21, 676).

TOLYLAMINE is TOLUIDINE (q.v.).

Di-*o*-tolyl-amine $NH(C_6H_4Me[1:2])_2$. (312° i.v.) at 728 mm. (Graebe, *A.* 238, 363). Obtained, together with diphenylamine by heating *o*-toluidine with aniline hydrochloride at 280° (Girard a. Willm, *Bl.* [2] 25, 248). Formed also by heating *o*-cresol with $ZnBr_2$, ammonia, and NH_4Cl at 835° (Merz a. Müller, *B.* 20, 547). Oil.

Di-*m*-tolyl-amine $NH(C_6H_4)_2$. (322°). Formed in like manner (Cosack, *B.* 13, 1091; Merz a. Müller, *B.* 20, 549). Oil, volatile with steam. Sl. sol. acids, v. sol. alcohol.

Acetyl derivative $NAc(C_6H_4)_2$. [48°].

Nitrosamine $(C_6H_4)_2N.NO$. [103°].

Di-*p*-tolyl-amine $NH(C_6H_4)_2$. [79°]. (831° i.v.) (Graebe, *A.* 238, 363). Formed by heating *p*-toluidine with its hydrochloride (Girard, *A.* 140, 346; Gerber, *B.* 6, 446). Formed also by heating *p*-cresol with $ZnCl_2$, ammonia, and NH_4Cl at 835° (Merz a. Müller, *B.* 20, 546). White needles. Its salts are decomposed by water.

Nitrosamine $(C_6H_4)_2N.NO$. [103°]. Yellow trimetric crystals (Lehne, *B.* 13, 1544; Cosack).

Acetyl derivative $(C_6H_4)_2N.AC$. [85°].

Benzoyl derivative $(C_6H_4)_2N.Bz$. [125°].

References.—TETRA-BROMO- and NITRO-DI-TOLYL-AMINE.

DI-*p*-TOLYL-ISOAMYL-AMINE $C_{15}H_{21}N$ i.e. $(C_6H_4)_2NCO_2H_{11}$. (290°–300° at 15 mm.). Formed by heating di-*p*-tolyl-amine with isoamyl alcohol and HCl in sealed tubes (Girard, *Bl.* [2] 24, 120).

TOLYL-ANILINE v. PHENYL-TOLUIDINE.

VOL. IV.

TOLYL-ARSINE v. ARSENIC.

TOLYL-AURAMINE $C_{21}H_{21}N_3$ i.e.

$C_6H_4Me.N:C(C_6H_4NMe)_2$. Formed from auramine hydrochloride and *p*-toluidine (Fehrmann, *B.* 20, 2853). Decomposed by H_2S in alcoholic solution at 50° into $CS(C_6H_4NMe)_2$ and *p*-toluidine.— $B'_2H_2PtCl_4$. Red flakes, v. sl. sol. water.

TOLYL-AZIMIDO-TOLUENE v. AZIMIDO-COMPOUNDS.

DI-*p*-TOLYL-TETRAZINE $C_{16}H_{16}N_4$ i.e.

$C_6H_4Me.N < \begin{smallmatrix} N=CH \\ CH=N \end{smallmatrix} > N.C_6H_4Me$. [185°]. Mol. w. 269 (obs.). Formed by the action of chloroform and alcoholic potash on *p*-tolyl-hydrazine (Ruhemann, *C. J.* 55, 248; 57, 51). Yellow plates (from hot alcohol). Yields a nitro-derivative $C_{15}H_{11}(NO_2)_4N_4$ [144°].

TOLYL-DISAZO-compounds v. DISAZO-COMPOUNDS.

TOLYL BENZAMIDE v. Benzoyl derivative of TOLUIDINE.

***p*-TOLYL-BENZAMIDINE** $C_{14}H_{14}N_2$ i.e.

$C_6H_4.C(NC_6H_4).NH_2$. [99°]. Formed from benzonitrile and toluidine hydrochloride (Bernthsen, *B.* 8, 1319; 9, 429). Forms a crystalline nitrate and oxalate.

Di-*p*-tolyl-benzamidine

$C_6H_4.C(NC_6H_4).NHC_6H_4$. [131°]. Formed by the action of *p*-toluidine on benzonitrile, and on ω -chloro-benzylidene-*p*-toluidine $C_6H_4N:CCl.C_6H_4$ (Bernthsen; Just, *B.* 19, 981). May be sublimed.

Reference.—AMIDO-TOLYL-BENZAMIDINE.

***p*-TOLYL-BENZAMIDOXIM** $C_{15}H_{15}N_2O$ i.e.

$C_6H_4.C(OH).NHC_6H_4$. [176°]. Formed by heating hydroxylamine hydrochloride with $C_6H_4.CS.NHC_6H_4$ and Na_2CO_3 at 100° (H. Müller, *B.* 22, 2406). White needles, sl. sol. hot water.— $B'HCl$: white needles, sl. sol. water. $ClCO_2Et$ converts it into $C_6H_4.C < \begin{smallmatrix} N.O \\ NC_6H_4 \end{smallmatrix} > CO$. [163°].

TOLYL-BENZENE v. METHYL-DIPHENYL.

Tri-*p*-tolyl-benzene $C_{27}H_{26}$ i.e. $C_6H_4(C_6H_4)_3$.

[171°]. Formed by passing dry HCl into *p*-tolyl methyl ketone for some days (Claus, *J. pr.* [2] 41, 402). Needles. Oxidised by CrO_3 to $C_6H_4(CO_2H)_3$. Yields $C_{27}H_{24}Br_3$ [212°].

***p*-TOLYL-BENZIMIDO-PHENYL ETHER**

$C_6H_4.C(NC_6H_4).OPh$. [120°]. Formed from $C_6H_4.CCl.NC_6H_4$ and $NaOPh$ (Hantzsch, *B.* 26, 927).

om-TOLYL-BENZOIC ACID

[1:3] $C_6H_4Me.C_6H_4.CO_2H$ [1:3']. [204°]. Formed by oxidation of [1:3] $C_6H_4Me.C_6H_4Me$ [1:8'] with dilute HNO_3 (Perrier, *C. R.* 114, 484). Silky needles, sol. alcohol, m. sol. Aq.

pp-Tolyl-benzoic acid

[1:4] $C_6H_4Me.C_6H_4.CO_2H$ [1:4']. [244°]. Formed by oxidation of *pp*-ditolyl by CrO_3 and $HOAc$ (Carnelley, *J.* 1877, 384). Sl. sol. hot water.— AgA' .

op-Tolyl-benzoic acid. [180°]. Formed by oxidation of [1:2] $C_6H_4Me.C_6H_4Me$ [1:4'] (Carnelley, *C. J.* 87, 707). Insol. water, sol. hot alcohol.

TOLYL-BENZYL-AMINE v. BENZYL-TOLUIDINE.

***p*-TOLYL-BENZYL-ISOBUTYL-UREA**

$C_{15}H_{21}N_2O$. [41°]. Got from *p*-tolyl-benzyl-carbamic chloride and isobutylamine (Hammerich, *B.* 25, 1824). Crystals (from ligroin).

p-TOLYL-BENZYL-CARBAMIC CHLORIDE $(C_6H_4Me)N(CH_2Ph).COCl$. Formed from *p*-tolyl-benzyl-amine and $COCl_2$ (Hammerich, *B.* 25, 1822). Oil.

p-TOLYL-BENZYL-CARBINOL $C_{11}H_{16}O$ *i.e.* $C_6H_4Me.CH(OH).CH_2Ph$. [66°]. (above 360°). Formed by reducing *p*-tolyl benzyl ketone in alcoholic solution by Na (Mann, *B.* 14, 1646). Small concentric needles, sol. alcohol and ether.

p-TOLYL-BENZYLENE-ACETAMIDINE $C_{16}H_{18}N_2$ *i.e.* $C_6H_4 \begin{smallmatrix} CH_2-NC_6H_5 \\ N=CMe \end{smallmatrix}$. [79°]. Formed by reduction of the acetyl derivative of *o*-nitro-benzyl-*p*-toluidine in acetic acid solution with tin and HCl (Lellmann a. Stickel, *B.* 19, 1610). Small glistening plates. V. sol. alcohol, ether, and chloroform.

p-TOLYL BENZYL KETONE $C_{15}H_{14}O$ *i.e.* $C_6H_4Me.CO.CH_2Ph$. [109°]. (above 360°). Formed by the action of $AlCl_3$ on a mixture of phenyl-acetyl chloride and toluene (Mann, *B.* 14, 1646; Strassmann, *B.* 22, 1229). Plates, sol. alcohol and ether. Na added to its alcoholic solution forms the carbinol and an acid $C_{15}H_{14}O_2$ [93°].

Oxim [131°]. Plates, insol. water.

o-TOLYL BENZYL OXIDE $C_{11}H_{10}O$ *i.e.* $[1:2] C_6H_4Me.O.CH_2Ph$. (285°–290°). Oil (Staedel, *B.* 14, 899). Converted by HNO_3 (S.G. 1.5) into a tri-nitro-derivative [145°].

m-Tolyl benzyl oxide. [43°]. (300°–305°). Tables (from alcohol), v. sol. ether.

p-Tolyl benzyl oxide [41°]. Formed from $C_6H_4Me.OK$ and CH_2PhCl (Frische, *A.* 224, 154). Crystals. Converted by HNO_3 (S.G. 1.5) into di-nitro-*p*-cresol [84°].

TOLYL-BENZYL-ISOPHOSPHINE $C_{11}H_{10}P$ or $C_{11}H_{12}P_2$. [187°]. An indifferent body formed by the action of zinc on a mixture of benzyl chloride and $C_6H_4MePCl_2$ (Michaelis a. Gleichmann, *B.* 15, 1963).

p-TOLYL BENZYL SULPHONE $C_{12}H_{10}Me.SO_2.CH_2Ph$. [145°]. Formed by the action of benzyl chloride on sodium toluene *p*-sulphinate (Otto, *B.* 13, 1278). Needles, sol. hot alcohol.

p-TOLYL-BENZYL-THIO-SEMICARBAZIDE $C_{11}H_{12}N_4S$. [121°]. Formed from benzyl thiocarbimide and *p*-tolyl-hydrazine (Dixon, *C. J.* 61, 1022). Prisms, sl. sol. cold alcohol.

o-TOLYL-BENZYL-THIO-UREA $C_{13}H_{16}N_2S$ *i.e.* $C_6H_4Me.NH.CS.NHCH_2Ph$. [139°]. Formed by boiling *o*-tolyl-thiocarbimide with benzyl-amine in alcohol (Dixon, *C. J.* 69, 656). Tufts of prisms, m. sol. hot alcohol.

m-Tolyl-benzyl-thio-urea. [114°]. Formed from benzyl-thiocarbimide and *m*-toluidine. Vitreous crystals, v. sl. sol. hot Aq.

p-Tolyl-benzyl-thio-urea [121°]. Crystals. **p-TOLYL-BENZYL-UREA** $CH_2Ph.NH.CO.NHC_6H_4Me$. [181°]. Formed from *p*-tolyl cyanate and benzylamine (Kühn a. Henschel, *B.* 21, 505).

p-Tolyl-di-benzyl-urea $C_{21}H_{22}N_2O$ *i.e.* $(CH_2Ph)_2N.CO.NHC_6H_4Me$. [169°]. Got from $(C_6H_5)_3N.COCl$ and *p*-toluidine (Hammerich, *B.* 25, 1820). Needles (from alcohol), insol. ether.

p-Tolyl-di-benzyl-urea $C_{21}H_{22}N_2O$ *i.e.* $CH_2Ph.N(C_6H_4Me).CO.NH.C_6H_4Ph$. [85°]. Formed from tolyl-benzyl-carbamic chloride and benzylamine (H.). Prisms, v. sol. alcohol.

Di-p-tolyl-benzyl-urea $C_{22}H_{24}N_2O$. [115°].

Formed from *p*-tolyl-benzyl-carbamic chloride and *p*-toluidine. Needles, v. sol. hot alcohol.

Di-p-tolyl-di-benzyl-urea

$(CH_2PhN(C_6H_4Me))_2CO$. [93°]. Got from *p*-tolyl-benzyl-carbamic chloride and *p*-tolyl-benzyl-amine. Crystalline, sol. alcohol.

DI-p-TOLYL-BIURET $(C_6H_4Me.NH.CO)_2NH$. [c. 220°]. Formed from *p*-tolyl-urea and *p*-tolyl cyanate at 160° (Kühn a. Henschel, *B.* 21, 506). White needles (from alcohol).

Tri-p-tolyl-biuret

$(C_6H_4Me.NH.CO)_2NC_6H_4Me$. [156°]. Formed from di-*p*-tolyl-urea and *p*-tolyl cyanate.

p-TOLYL-BORIC ACID $C_6H_4Me.B(OH)_2$. [240°]. Formed by the action of water on boron-*p*-tolyl-dichloride (v. vol. i. p. 531). Needles, sol. hot water. $HgCl_2$ gives a white pp. of C_6H_4HgCl .

TOLYL-BROMO-ETHYLENE *v.* **BROMO-TOLYL-ETHYLENE**.

TOLYL BROMO-METHYL KETONE

$C_6H_4Me.CO.CH_2Br$. [55°]. Formed by the action of hot water on di-*exo*-bromo-*exo*-methyl-atrolactic acid (Böttinger, *B.* 14, 1598). Crystals, volatile with steam, sol. water and ether.

p-TOLYL BROMO-METHYL SULPHONE

$C_6H_4Me.SO_2.CH_2Br$. [92°]. Formed by the action of bromine on an aqueous solution of $C_6H_4SO_2.CH_2.CO_2H$ (Otto, *J. pr.* [2] 40, 544). Formed also from $C_6H_4SO_2Na$ and CH_2Br_2 . Thin monoclinic needles, sol. hot alcohol.

p-Tolyl di-bromo-methyl sulphone

$C_6H_4Me.SO_2.CHBBr_2$. [117°]. Formed from tolyl-sulphono-acetic acid and Br (O.). Monoclinic prisms, v. sol. hot alcohol.

TOLYL-BUTANE *v.* **BUTYL-TOLUENE**.

m-TOLYL-BUTYLENE $C_6H_4Me.CH_2.C_4H_9$. (195°). Formed from $C_6H_4Me.CH_2Cl$, allyl iodide, and Na (Aronheim, *B.* 19, 1790). Oil. Yields a liquid dibromide.

p-TOLYL-p-BUTYL-PHENYL-THIO-UREA

$C_6H_4Me.NH.CS.NH.C_6H_4.C_4H_9$. [137°]. Formed from isobutyl-phenyl-amine and *p*-tolyl-thiocarbimide (Mainzer, *B.* 16, 2024). Plates, sol. alcohol and ether.

DI-p-TOLYL-ISOBUTYL-UREA $C_{15}H_{20}N_2O$.

[119°]. Formed from $(C_6H_5)_3N.COCl$ and isobutylamine (Hammerich, *B.* 25, 1822). Prisms, v. sol. alcohol and ether.

m-TOLYL-ISOBUTYRIC ACID

$C_6H_4Me.CH_2.CHMe.CO_2H$. [92°]. Formed by oxidation of *m*-isobutyl-toluene by dilute HNO_3 (Kelbe, *B.* 16, 620). Needles (from ligroin).—AgA': pp.

Reference.—**NITRO-TOLYL-ISOBUTYRIC ACID**.

o-TOLYL-CARBAMIC ACID $C_6H_4NO_2$ *i.e.* $C_6H_4Me.NH.CO_2H$.

Ethyl ether EtA'. [42°] (C.); [46°] (L.). Formed from *o*-toluidine and $ClCO_2Et$ (Cosack, *B.* 12, 1450; Neville a. Winther, *B.* 12, 2324). Formed also from $C_6H_4Me.COCl.NCl$ and alcoholic potash (Lachmann, *B.* 12, 1349). Tables, sol. alcohol and benzene. Volatile with steam. Yields *o*-tolyl cyanate on distilling with P_2O_5 .

Isobutyl ether C_4H_9A' . (275°–280°). Oil (Mylius, *B.* 5, 974). Partially decomposed on distillation into tolyl cyanate and isobutyl alcohol.

Benzyl ether CH_2PhA' . [84°]. Formed from *o*-tolyl cyanate and benzyl alcohol (Gattermann a. Cantzler, *B.* 25, 1087). Needles

Phenyl ether PhA'. [92°]. Formed by boiling di-*o*-tolyl-urea with di-phenyl carbonate for some hours (Eckenroth & Rückel, *B.* 23, 699). Crystals (from ligroin).

***m*-Phenylene ether $C_6H_4A_2$.** [154°]. Formed by heating *o*-tolyl cyanate with resorcin at 120° (G. a. C.). Colourless plates.

***p*-Phenylene ether $C_6H_4A_2$.** [206-5°]. Formed by heating *o*-tolyl cyanate with hydroquinone at 150°.

***o*-Tolyl ether C_6H_4A' .** [126°]. Formed from *o*-tolyl cyanate and *o*-cresol (G. a. C.). Needles.

(β)-Naphthyl ether $C_{10}H_7A'$. [149°]. Formed by heating *o*-tolyl cyanate with (β)-naphthol at 160° (G. a. C.). Plates.

Di-phenyl-ethylene ether $C_2H_5Ph_2A_2$. [234°]. Formed by heating *o*-tolyl cyanate with hydrobenzoin at 100° (Auwers, *B.* 24, 1778). Needles. An isomeride [163°] is obtained from isohydrobenzoin.

***m*-Tolyl-carbamic acid**

[1:3] $C_6H_4Me.NH.CO_2H$.

Ethyl ether $C_{10}H_{13}NO_2$. Prepared from *m*-toluidine and chloroformic ether (Cosack, *B.* 13, 1090). Oil, v. sol. alcohol and ether.

***p*-Tolyl-carbamic acid**

[1:4] $C_6H_4Me.NH.CO_2H$.

Ethyl ether EtA'. [52°]. Formed from *p*-toluidine and $ClCO_2Et$ (Hofmann, *Pr.* 19, 108; *B.* 3, 656). Monoclinic prisms, v. sol. alcohol (Levin, *J.* 1882, 384).

Phenyl ether PhA'. [115°]. Formed by distilling di-*p*-tolyl-urea with di-phenyl carbonate (Eckenroth & Rückel, *B.* 23, 698). Needles (from hot ligroin).

Di-*p*-tolyl-carbamic acid $(C_6H_4)_2N.CO_2H$.

Ethyl ether EtA'. [62°]. Formed from $(C_6H_4)_2N.COCl$ and $NaOEt$ (Hammerich, *B.* 25, 1824). Large plates, v. sol. alcohol and ether.

Chloride $(C_6H_4)_2N.COCl$. [103°]. Formed from $COCl_2$, a solution of di-*p*-tolyl-amine in benzene, and conc. $NaOHAq$ (Hammerich, *B.* 25, 1821). Needles (from alcohol), v. e. sol. ether. $AgCy$ forms the compound $(C_6H_4)_2N.CO.CN(AgCy)$, crystallising in needles which begin to melt at 103°.

***o*-TOLYL-CARBAMINE** [1:2] $C_6H_4Me.N:C$. (184°). S.G. 24.968. Formed by the action of alcoholic potash on *o*-toluidine and chloroform (Nef, *A.* 270, 309). Oil, volatile with steam. When heated at 245° for 3 hours it changes to the isomeric *o*-toluic nitrile. Heated with S in CS_2 at 130° it yields *o*-tolyl thiocarbimide. H_2S at 100° forms $C_6H_4Me.NH.CHS$ [101°].

Chloride $C_6H_4Me.N:CCl_2$. (215°). Formed by passing chlorine into a chloroform solution of the carbamine.

***p*-Tolyl-carbamine $C_6H_4Me.N:C$.** (99° at 36 mm.). Formed in like manner from *p*-toluidine (Nef). Oil.

Chloride $C_6H_4Me.N:CCl_2$. (226°). Converted by *p*-toluidine into tri-*p*-tolyl-guanidine.

***o*-TOLYL-SEMI-CARBAZIDE $C_6H_4N_3O$ i.e. $NH_2.CO.NH_2.C_6H_4$.** [160°]. Formed by heating *o*-tolyl-hydrazine with urea (Pinner, *B.* 21, 1219). Flat needles, m. sol. water.

***p*-Tolyl-semi-carbazide $C_6H_4N_3O$.** [158°]. Sl. sol. cold water. Reduces Fehling's solution.

Di-*p*-tolyl-carbaside $CO(NH.NHC_6H_4)_2$. [201°]. Formed from *p*-tolyl-hydrazine and

carbamic ether (Preund, *B.* 24, 4197). Tables, insol. water, v. sol. hot alcohol.

TOLYL-CARBIMIDE v. TOLYL ISOCYANATE, vol. ii. p. 316.

***o*-TOLYL-CARBINOL C_6H_4O i.e.**

[1:2] $C_6H_4Me.CH_2OH$. *o*-Oxy-*o*-xylene. Mol. w. 122. [34°]. (223° i. v.). S.G. 1.02. Sl. in the cold; 1.5 at 100°. Formed by boiling *o*-bromo-*o*-xylene with $KOHAq$ (Colson, *Bl.* [2] 43, 8; *A. Ch.* [6] 6, 116). Formed also by reducing the aldehyde $C_6H_4Me.CHO$ (Raymann, *Bl.* [2] 27, 498), by the action of HNO_2 on the amine $C_6H_4Me.CH_2NH_2$ (Kröber, *B.* 23, 1028), and by reducing *o*-toluic amide in acid solution by sodium-amalgam (Hutchinson, *B.* 24, 174). Needles, v. sol. alcohol and ether, sol. hot water. Oxidised by alkaline $KMnO_4$ to *o*-toluic acid [103°].

***m*-Tolyl-carbinol** [1:3] $C_6H_4Me.CH_2OH$. (217°). S.G. 1.036 (C.); 1.916 (R. a. W.). Sl. in the cold. Formed by boiling the bromide $C_6H_4Me.CH_2Br$ with alkalis (C.). Liquid, v. sol. alcohol and ether, sl. sol. cold water. Yields *m*-toluic acid [108°] on oxidation.

Ethyl ether $C_7H_7.CH_2.OEt$. (202°) at 740 mm. S.G. 1.93. Oil.

Acetyl derivative $C_6H_4.CH_2.OAc$. (226°). Formed from $C_6H_4.CH_2Br$ and $KOAc$ (Radziszewski, *A.* Wispek, *B.* 15, 1747). Oil.

***p*-Tolyl-carbinol** [1:4] $C_6H_4Me.CH_2OH$. [59°]. (217°). Formed from *p*-toluic aldehyde and alcoholic potash (Cannizzaro, *C. R.* 54, 1225; *A.* 124, 255). Needles, sl. sol. cold water.

Ethyl ether $C_6H_5.OEt$. (203°) at 740 mm. S.G. 1.93. Formed from *o*-bromo-*p*-xylene and alcoholic potash (Radziszewski, *A.* Wispek, *B.* 15, 1745). Oil.

Di-tolyl-carbinol $(C_6H_4Me)_2CH.OH$. [69°] (W.); [62°] (Ador & Crafts, *B.* 10, 2175). Formed by reducing di-tolyl ketone with sodium-amalgam (Weller, *B.* 7, 1184). Needles (from alcohol), insol. water.

Reference.—OXY-TOLYL-CARBINOL.

TOLYL-CARBINYL-AMINE v. METHYL-BENZYL-AMINE.

DI-*p*-TOLYL-CARBINYL AMINE

$(C_6H_4)_2CH.NH_2$. [93°]. Formed by reducing the oxim of di-*p*-tolyl ketone in alcoholic solution with sodium-amalgam and $HOAc$ at 60° (Goldschmidt & Stöcker, *B.* 24, 2798). Tables. — $B'HCl$. [235°]. White needles.

Acetyl derivative [159°]. Needles.

TOLYL-CARBINYL-UREA v. METHYL-BENZYL-UREA.

Di-*p*-tolyl-carbinyl-urea

$NH_2.CO.NH.CH(C_6H_4)_2$. [152°]. Formed from the hydrochloride of the amine and $KCyO$ (Goldschmidt, *B.* 24, 2799). Needles.

DI-*p*-TOLYL-CARBONATE $(C_6H_4O)_2CO$.

[115°]. Formed, together with di-ethyl carbonate, by heating *p*-tolyl ethyl carbonate at 300° (Bender, *B.* 19, 2268). V. sl. sol. cold alcohol.

DI-TOLYL DICARBOXYLIC ACID

[3:4:1] $C_6H_4Me(CO_2H).C_6H_4Me(CO_2H)$ [1:3:4] [over 300°]. Formed by heating its nitrile with dilute H_2SO_4 (Löwenherz, *B.* 25, 1036). Plates, insol. water, sl. sol. hot alcohol.

Nitrile $C_{12}H_{12}(CN)_2$. [190°]. Formed from di-amido-ditolyl by Sandmeyer's diazo-reaction. Needles, m. sol. cold alcohol.

Reference.—OXY-DITOLYL DICARBOXYLIC ACID, TOLYL CHLORIDE v. *o*-CHLORO-XYLENE.

p-TOLYL CHLORO-BENZYL SULPHONE

$C_6H_4Me.SO_2.CHCl.C_6H_5$. [203°]. Formed by heating sodium toluene *p*-sulphinate with benzylidene chloride (Otto, *J. pr.* [2] 40, 519). Needles (from HOAc).

p-TOLYL CHLORO-ETHYL SULPHONE

$[1:4] C_6H_4Me.SO_2.CHCl.CH_3$. [48°]. Formed by boiling $CH_3.COCl.CO_2Na$ (1 mol.) with $C_6H_4SO_2Na$ (2 mols.) in aqueous solution. Formed also by heating ethylidene chloride (2.5 g.) with sodium toluene *p*-sulphinate (4.5 g.) and alcohol at 150° (Otto, *J. pr.* [2] 40, 515, 534). Trimetric tables, v. sol. hot alcohol. Does not act upon $C_6H_4SO_2Na$ even at 200°.

p-Tolyl chloro-ethyl sulphone

$C_6H_4Me.SO_2.CH_2.CH_2Cl$. [79°]. Formed from $C_6H_4Me.SO_2.CH_2.CH_2OH$ and PCl_5 (Otto, *J. pr.* [2] 30, 357). Needles or plates, v. sol. hot alcohol.

p-TOLYL CHLORO-METHYL SULPHONE

$C_6H_4Me.SO_2.CH_2Cl$. [84°]. Formed by heating an aqueous solution of $CHCl_3.CO_2Na$ (1 mol.) with $C_6H_4SO_2Na$ (2 mols.) on the water-bath (Otto, *J. pr.* [2] 40, 528). Tables (from benzene), v. sol. hot alcohol.

p-Tolyl di-chloro-methyl sulphone

$C_6H_4Me.SO_2.CHCl_2$. [114°]. Formed by passing chlorine into a warm aqueous solution of $C_6H_4SO_2CH_2.CO_2H$ (Otto, *J. pr.* [2] 40, 544). Crystals, insol. water, v. sol. hot alcohol.

TOLYL-CRESOL $C_6H_4Me.CH_2.C_6H_4.OH$. (250°–255° at 10 mm.). Formed by heating *o*-chloro-xylene with phenol and zinc filings (Mazzara, *G.* 9, 421). Oil, sol. alcohol, ether, and alkalis. Not coloured by $FeCl_3$.

Acetyl derivative (250° at 9 mm.). Decomposed in moist air into HOAc and tolyl-cresol.

p-TOLYL-CUMINYL-AMINE $C_{11}H_{21}N$ i.e. $C_6H_4Me.NH.CH_2.C_6H_5$. [36°]. (above 200°). Formed by the reduction by sodium-amalgam of the product of the action of cuminal on *p*-toluidine (Uebel, *A.* 245, 293). Plates or prisms.— $B'HCl$. Plates or needles, sl. sol. hot Aq.

Nitrosamine $C_6H_4Me.NO$. [67°]. Prisms.

p-TOLYL-CUMINYL-UREA $C_{13}H_{22}N_2O$ i.e. $C_6H_4Me.NH.CO.NHC_6H_5$. [150°]. Formed from cuminylamine and *p*-tolyl cyanate (Goldschmidt a. Gessner, *B.* 22, 928). Needles, v. sol. alcohol.

p-TOLYL-CUMYLIDENE-AMINE

$C_6H_4Me.N:CH.C_6H_5$. [51°]. Formed from cuminaldehyde (cuminal) and *p*-toluidine in alcoholic solution (Uebel, *A.* 245, 292). Yellowish plates (from alcohol). Decomposed into the parent substances by heating with acids and alkalis.

p-TOLYL-ψ-CUMYL-UREA

$C_6H_4Me.NH.CO.NH.C_6H_5Me$. [218°]. Formed from $ψ$ -cumidine and *p*-tolyl cyanate (Goldschmidt a. Bardach, *B.* 25, 1861). Needles.

o-TOLYL-CYANAMIDE $C_6H_4Me.NH.CN$.

[77°]. Formed by heating $C_6H_4NH.CS.NH.OH$ or by the action of hydroxylamine on *o*-tolyl thiocarbimide (Tiemann, *B.* 22, 1940; Voltmer, *B.* 24, 381). Tables, v. sol. alcohol and KOHAq, m. sol. water.

DI-o-TOLYL-CYANAMIDE $C_{13}H_{21}N_4$ i.e. $C(NC_6H_4)_2$. **Carbodi-tolylimide**. (above 300°). Formed by heating the alkyl derivatives of di-*o*-tolyl-thio-urea (Will a. Bielschowski, *B.* 15,

1817). Amorphous, v. sol. benzene. Converted by dilute $HClAq$ into di-*o*-tolyl-urea.

Di-p-tolyl-cyanamide $C_{11}H_{21}N_3SO$ or $C(NC_6H_4)_2$. [80°]. (above 230°). Formed by the action of HgO on a benzene solution of di-tolyl-thio-urea (Will, *B.* 14, 1488). Thick prisms, sol. benzene and ether. On heating with aniline it gives phenyl-di-tolyl-guanidine. Acids and alkalis convert it into di-*p*-tolyl-urea. On distillation it yields compounds melting at 49° to 60° and at 149° (Schall a. Paschkowitzky, *B.* 25, 2892). Phenyl-hydrazine at 190° forms $C_{20}H_{25}N_5$ [163°], which crystallises from alcohol in plates, and yields $B'4HCl$ and $B'2H.PtCl_4$. On heating with phenyl-hydrazine at 165° there is formed $N_2PhH:C(NO_2H)_2$ [188°], crystallising in pale-red needles, yielding $B'4H.PtCl_4$ (Wessel, *B.* 21, 2274). Tolyene-*o*-diamine at 140° forms $C_{22}H_{24}N_4$ [196°], which yields $B'3HCl$ [143°] (Dahm a. Gasiorowski, *B.* 19, 3057).

TOLYL CYANATE v. CYANIC ACID.**TOLYL CYANIDE** v. Nitrile of TOLUIC ACID.**TOLYL-CYANURIC ACID** v. CYANIC ACIDS.**TOLYLENE ALCOHOL** v. DI-OXY-XYLENE.**TOLYLENE-DI-ALLYL-DI-THIO-DI-UREA**

[1:2:3] $C_6H_4Me(NH.CS.NHC_6H_5)_2$. $ε$ [152°]. Formed from *c*-tolylene-*o*-diamine and oil of mustard (Lellmann, *A.* 228, 246). Needles (from alcohol), decomposed on fusing into tolylene-thio-urea and di-allyl-thio-urea.

Tolyene-di-allyl-di-thio-di-urea

[1:3:4] $C_6H_4Me(NH.CS.NHC_6H_5)_2$. [150°]. Formed from *t*-tolylene-*o*-diamine and oil of mustard (Lellmann, *A.* 221, 24). Decomposed by heat like the preceding isomeride; melting a second time at 210°–230°.

Tolyene-di-allyl-di-thio-di-urea

[1:2:5] $C_6H_4Me(NH.CS.NHC_6H_5)_2$. [175–5°]. Formed from tolylene-*p*-diamine and allyl thiocarbimide (Lellmann a. Würthner, *A.* 228, 209). Plates or prisms, nearly insol. ether.

Tolyene-di-allyl-di-thio-di-urea

[151°]. Formed from tolylene-*m*-*o*-diamine and allyl thiocarbimide. Prisms (from alcohol), insol. ether, v. sol. HOAc. Melts without decomposition.

TOLYLENE-DI-AMIDO-DI-ACETIC ETHER

[1:2:4] $C_6H_4Me(NH.CH_2.CO_2Et)_2$. [70°]. Formed from tolylene-*m*-diamine and chloro-acetic ether (Zimmermann a. Knyrim, *B.* 16, 516). Needles (from water).

c-TOLYLENE-o-DIAMINE $C_6H_4N_2$ i.e.

$C_6H_4Me(NH_2)_2$. [1:2:3]. Mol. w. 122. [62°]. (255°). Formed from $C_6H_4Me(NH_2)(NO_2)$ [1:2:3] by reducing with Sn and HCl (Lellmann, *A.* 228, 243). Reddish crystals, smelling of acetamide. — $B''2HCl$. Sol. water, ppd. by HCl .

c-Tolyene-m-diamine $C_6H_4Me(NH_2)_2$ [1:2:6].

[104°]. Formed by reduction of nitro-toluidine [92°], or of liquid di-nitro-toluene (Ullmann, *B.* 17, 1960). Prisms, sol. hot water. Gives a brown colour with nitrous acid. CrO_3 and $FeCl_3$ give a brown colour. — $B'HCl$: crystals, v. e. sol. water.

i-Tolyene-m-diamine $C_6H_4Me(NH_2)_2$ [1:2:4].

[99°]. (α. 280°). Formed by reducing di-nitro-toluene (Hofmann, *Pr.* 11, 518) by reducing (4,1,2)-nitro-toluidine (Nölting a. Collin, *B.* 17, 268), and by the action of $SnCl_2$ on amido-toluene-azo-amido-cresol (Graeff, *A.* 229, 848). Needles (from water), v. sol. alcohol, ether, and

hot water. Chloroformic ether, ClCO_2Et , forms [1:2:4] $\text{C}_6\text{H}_4\text{Me}(\text{NH}_2)(\text{NH}\cdot\text{CO}_2\text{Et})$ [91°], and chiefly $\text{C}_6\text{H}_4\text{Me}(\text{NH}\cdot\text{CO}_2\text{Et})_2$ [137°] (Schiff, *A.* 268, 314). Phenyl-thio-carbimide yields $\text{CO}_2\text{Et}\cdot\text{NH}\cdot\text{C}_6\text{H}_4\text{Me}\cdot\text{NH}\cdot\text{CS}\cdot\text{NHPh}$ [155°]. Heptotic aldehyde in the cold forms $\text{C}_6\text{H}_4\text{N}_2(\text{C}_6\text{H}_5)_2$, but when heated it yields an orange mass which forms a highly fluorescent solution (Schiff a. Vanni, *A.* 253, 319). Benzoic aldehyde forms $\text{C}_6\text{H}_4(\text{N}\cdot\text{CHPh})_2$ [122°–128°], while cinnamic aldehyde gives $\text{C}_6\text{H}_4(\text{NC}_6\text{H}_5)_2$ [162°] (Schiff, *A.* 140, 98; 239, 384). $\text{Cl}\cdot\text{CO}\cdot\text{CO}_2\text{Et}$ forms $\text{C}_6\text{H}_4\text{Me}\langle\text{NH}\cdot\text{CO}\cdot\text{NH}\cdot\text{CO}\rangle$ [c. 260°] and [1:2:4] $\text{C}_6\text{H}_4\text{Me}(\text{NH}_2)\cdot\text{NH}\cdot\text{CO}\cdot\text{CO}_2\text{Et}$ [170°], which yields an acetyl derivative [192°]. Phenyl-thiocarbimide forms the compound $\text{NHPh}\cdot\text{CS}\cdot\text{NH}\cdot\text{C}_6\text{H}_4\text{Me}\cdot\text{NH}\cdot\text{CO}\cdot\text{CO}_2\text{Et}$ [155°] and $\text{C}_6\text{H}_4\text{Me}\langle\text{NH}\cdot\text{CS}\cdot\text{NH}\cdot\text{C}_6\text{H}_5\rangle\text{NPh}$ [198°] (Schiff, *A.* 268, 307). Tolylene-*m*-diamine heated with citric acid at 125° forms $\text{C}_{13}\text{H}_{12}\text{N}_2\text{O}_4$, crystallising from boiling alcohol in minute octahedra, decomposing at about 187° (Schneider, *B.* 21, 665). Acetyl-acetone at 100° forms a syrup, which when heated with H_2SO_4 yields $\text{C}_{12}\text{H}_{14}\text{N}_2$ [191°] (Combes, *C. R.* 108, 1252).— B^*HCl .— B^*HCl .— B^*HCl .— B^*HBr .— $\text{B}^*\text{H}_2\text{SO}_4$, 2aq: prisms. *S.* 5:6 at 19.5 (Beilstein a. Kuhlberg, *A.* 158, 351).— $\text{B}^*\text{H}_2\text{PtCl}_6$.— $\text{B}^*\text{H}_2\text{Cys}$. Prisms (Lussy, *B.* 7, 1265).

o-Acetyl derivative

$\text{C}_6\text{H}_4\text{Me}(\text{NHAc})\text{NH}_2$ [1:2:4]. [140°]. Formed from $\text{C}_6\text{H}_4\text{Me}(\text{NH}_2)(\text{NO}_2)$ [107°] by acetylation and reduction (Wallach, *A.* 234, 350). Needles. — $\text{B}^*\text{H}_2\text{PtCl}_6$.

p-Acetyl derivative

$\text{C}_6\text{H}_4\text{Me}(\text{NH}_2)(\text{NHAc})$ [1:2:4]. [160°]. Formed by acetylating the diamine, and got also by reducing $\text{C}_6\text{H}_4\text{Me}(\text{NO}_2)(\text{NHAc})$ [1:2:4] (Tiemann, *B.* 3, 221; Wallach, *B.* 15, 2826, 2831). Long white needles.

Di-acetyl derivative $\text{C}_6\text{H}_4\text{Me}(\text{NHAc})_2$ [224°]. Got by boiling the base with Ac_2O or HOAc (Koch, *A.* 153, 132; Tiemann, *B.* 3, 8; Ladenburg, *B.* 8, 1211). Needles.

Benzoyl derivative

$\text{C}_6\text{H}_4\text{Me}(\text{NO}_2)(\text{NHBz})$ [1:2:4]. [142°]. Got by reducing $\text{C}_6\text{H}_4\text{Me}(\text{NO}_2)(\text{NHBz})$ (Bell, *B.* 7, 1505).

Di-benzoyl derivative [224°]. Tables, sl. sol. alcohol (Ruhemann, *B.* 14, 2656).

Thiobenzoyl derivative

$\text{C}_6\text{H}_4\text{Me}(\text{NH}_2)\text{NH}\cdot\text{CSPh}$. [197°] (Bernthsen a. Trompeter, *B.* 11, 1760).

Phthalyl derivative

$\text{C}_6\text{H}_4\text{Me}\langle\text{NH}\cdot\text{CO}\cdot\text{NH}\cdot\text{CO}\rangle\text{C}_6\text{H}_4$. [192°]. Formed from the base and phthalic anhydride (Biedermann, *B.* 10, 1161). Needles, split up by dilute HCl into phthalic acid and a base $\text{C}_8\text{H}_8\text{N}_2\text{O}_4$.

Di-phthalyl derivative

$\text{C}_6\text{H}_4\text{Me}(\text{NOC}_6\text{H}_4\text{O}_2)_2$. [233°]. Crystals, insol. water and alcohol.

s-Tolylene-*m*-diamine $\text{C}_6\text{H}_4\text{Me}(\text{NH}_2)_2$ [1:3:5]. (284°). Formed by reducing *s*-di-nitro-toluene (Staedel, *A.* 217, 202). Syrup.— $\text{B}^*\text{H}_2\text{SO}_4$.— $\text{B}^*\text{H}_2\text{SnCl}_4$: crystals, v. sol. water.

Tolylene-*p*-diamine $\text{C}_6\text{H}_4\text{Me}(\text{NH}_2)_2$ [1:2:5]. [64°]. (274°). Formed by reducing (5,1,3)- and (2,1,5)-nitro-toluidines (Beilstein a. Kuhlberg, *A.* 158, 352; Fileti a. Crossa, *G.* 18, 306), and $\text{C}_6\text{H}_4\text{Me}\cdot\text{N}_2\cdot\text{C}_6\text{H}_4\text{Me}\cdot\text{NH}_2$ [2:1:5] or [5:1:2]

(Nietzki, *B.* 10, 832, 1158). Plates (from benzene), v. sol. water, alcohol, and ether. Forms toluquinone on oxidation. FeCl_3 added to a solution of tolylene-*p*-diamine hydrochloride mixed with *o*-toluidine gives an intense green colour.— B^*HCl . Plates.— $\text{B}^*\text{H}_2\text{SO}_4$. *S.* 84 at 11.5°.

Di-acetyl derivative $\text{C}_6\text{H}_4\text{Me}(\text{NHAc})_2$. [220°]. Prisms (from dilute alcohol) (Nietzki, *B.* 10, 1157; 12, 2237).

Tolylene-*o*-diamine $\text{C}_6\text{H}_4\text{Me}(\text{NH}_2)_2$ [1:3:4]. [88–5°]. (265°). Formed by reducing (3,1,4)-nitro-*p*-toluidine (Beilstein a. Kuhlberg, *A.* 158, 351; Graeff, *A.* 229, 343). Plates, m. sol. cold water. Its aqueous solution quickly blackens when exposed to air. FeCl_3 forms by oxidation $\text{C}_{14}\text{H}_{10}\text{N}_2\text{O}$, crystallising from wood spirit in brownish-red plates [247°] (O. Fischer a. Sieder, *B.* 23, 3802).

Reactions.—1. *Benzoic aldehyde* at 140°

forms $\text{C}_{21}\text{H}_{18}\text{N}_2$ or $\text{C}_6\text{H}_4\langle\text{N}(\text{C}_6\text{H}_5)\rangle\text{CPh}$ [195–5°]

(Ladenburg, *B.* 11, 591, 1656; Hinsberg, *B.* 19, 2026; 20, 1585), which yields B^*MeI [209°], B^*EtI [181°], and B^*EtI_2 [125°], and is oxidised by KMnO_4 to an acid $\text{C}_{21}\text{H}_{18}\text{N}_2\text{O}_4$ [254°].—2. *Furfuraldehyde*, acting on the hydrochloride, forms $\text{C}_{14}\text{H}_{12}\text{N}_2\text{O}_2$ [128–5°], which yields B^*MeI [195–5°], B^*MeI_2 [128°], and B^*MeI_3 [109°].—3. *Acetic aldehyde* (2 mols.) added to a cold solution of the base (1 mol.) in glacial acetic acid forms

$\text{C}_6\text{H}_4\langle\text{NEt}\rangle\text{CMe}$ (Hinsberg).—4. *Anisic aldehyde*, added to a dilute aqueous solution of tolylene-*o*-diamine hydrochloride containing a little alcohol, forms $\text{C}_{20}\text{H}_{18}\text{N}_2\text{O}_2$ [152°–156°], which separates on addition of ammonia (*L.*).—5. *Salicylic aldehyde* at 110° forms $\text{C}_{20}\text{H}_{18}\text{N}_2\text{O}_2$ [106°–110°], and at 135° it forms azurine $\text{C}_{20}\text{H}_{18}\text{N}_2\text{O}_4$ [250–5°], which exhibits blue fluorescence in alkaline solutions.—6. *Glucose* (2 mols.) added to an alcoholic solution of tolylene-*o*-diamine forms $\text{C}_6\text{H}_4(\text{N}\cdot\text{C}_6\text{H}_4\text{O}_2)_2$, crystallising in satiny needles, v. sol. water [c. 160°], which gives a red colour with FeCl_3 . Glucose converts tolylene-*o*-diamine acetate into amorphous 'glycodiamidom-toluene' $\text{C}_{13}\text{H}_{18}\text{N}_2\text{O}_4$, m. sol. water (Hinsberg, *B.* 20, 495; Griess a. Harrow, *B.* 20, 2209). Glucoson $\text{C}_6\text{H}_{10}\text{O}_6$ acts in aqueous solution on phenylene-*o*-diamine, forming $\text{C}_{13}\text{H}_{18}\text{N}_2\text{O}_4$ [c. 180°] (E. Fischer, *B.* 22, 93).—7. *Arabinose* forms $\text{C}_{13}\text{H}_{18}\text{N}_2\text{O}_4$ [238°] (G. a. H.).—8. *Acrolein* in boiling aqueous solution forms tolylene-*o*-diamine acrosan [185°] (Fischer a. Tafel, *B.* 22, 99).—9. *Formic aldehyde* forms $\text{C}_{13}\text{H}_{18}\text{N}_2$ [222°] (Fischer a. Wrezniski, *B.* 25, 2713).—10. *Butyric aldehyde* forms tolylene-butenyl-diamine

$\text{C}_6\text{H}_4\langle\text{N}\rangle\text{CPr}$ [158°], and the compound

$\text{C}_{13}\text{H}_{18}\text{N}_2$ or $\text{C}_6\text{H}_4\langle\text{N}(\text{C}_6\text{H}_5)\rangle\text{CPr}$ (Hinsberg, *B.* 20, 1590).—11. *Nitrous acid* or, better, amyl nitrite acting on a salt of tolylene-*o*-diamine forms azimido-toluene $\text{C}_6\text{H}_4\text{N}_2$ [84°] (823°), which is v. sol. alcohol and hot toluene (Zincke a. Lawson, *A.* 240, 115; cf. Ladenburg, *B.* 9, 220; Bössneck, *B.* 19, 1759; Nölting a. Abt, *B.* 20, 3001). Azimido-toluene forms the salts $\text{B}^*\text{H}_2\text{PtCl}_6$, $\text{NaC}_6\text{H}_4\text{N}_2\cdot\text{Hg}(\text{C}_6\text{H}_5)_2$ [285°], and $\text{AgC}_6\text{H}_4\text{N}_2$. AcCl converts azimido-toluene into

the (β)-acetyl derivative $C_6H_4 \begin{smallmatrix} \diagup N \\ \diagdown N \end{smallmatrix} NAc$ [94°], while the isomeric (α)-acetyl derivative $C_6H_4 \begin{smallmatrix} \diagup NAc \\ \diagdown N \end{smallmatrix}$ [132°] is formed by the action of nitrous acid on the acetyl derivative of tolylene-*o*-diamine.—12. Boiling *chloro-acetic ether* forms oxytoluinoxaline dihydride and a compound $C_{15}H_{18}N_2O_5$ (?) [147°], whence HNO_3 forms a compound [248°] (Hinsberg, *A.* 237, 365).—13. *Isatin* yields $C_{15}H_{11}N_3$ [290°], sl. sol. alcohol (Hinsberg, *A.* 237, 344).—14. Equal mols. of tolylene-*o*-diamine and *acetoacetic ether* when gently warmed together eliminate H_2O , and form a condensation product $C_{15}H_{18}N_2O_5$ [82°]; if this is heated at 100°–120° acetic ether is evolved, and a tolylene-ethenyl-*o*-diamine $C_6H_4Me \begin{smallmatrix} \diagup NH \\ \diagdown N \end{smallmatrix} \gg C_6H_5$ is produced (Ladenburg a. Rügheimer, *B.* 12, 953; Witt, *B.* 19, 2977, 3299).—15. *Chloro-acetoacetic ether* forms $C_6H_4(NH)_2CMe.CHCl.CO_2Et$ [110°], crystallising in needles (Autenrieth a. Hinsberg, *B.* 25, 606).—16. *Oxydehydracetic acid* forms $C_6H_4O_3(C_6H_4Me(NH_2)_2)$ [147°] (Feist, *B.* 25, 825).—17. *o-Aldehyde-benzoic acid* in hot water forms $C_6H_4Me \begin{smallmatrix} \diagup N \\ \diagdown NH \end{smallmatrix} \gg C_6H_4.CO_2H$ [258°]

(Bistrzycki, *B.* 23, 1043).—18. *Di-oxy-quinone* forms di-oxy-methyl-phenazine $C_{15}H_{10}N_2O_2$ [c. 265°], which yields a di-acetyl derivative [160°]. 19. *Opianic acid* gives, in alcoholic solution at 0°, the acid $C_6H_4Me:(N_2H):C_6H_4(OMe)_2.CO_2H$, crystallising in needles, decomposing at 234° (Bistrzycki, *B.* 24, 627).—20. *Di-bromo-pyruvic acid* (1 mol.) forms, on boiling, $C_6H_4 \begin{smallmatrix} \diagup N:C.OHBr \\ \diagdown N:C.OH \end{smallmatrix}$ [235°].

Salts.— $B''H_2HCl$. Needles (Hübner, *A.* 209, 364).— $B''H_2SO_4$ 1½ aq. Scales. S. 9·29 at 19·5°. — $B''H_2C_2O_4$ aq (Hinsberg, *B.* 16, 1532). Compound with pyrocatechin $B''C_6H_4O_3$ [78°]. Needles (from ligroin) (Merz, *B.* 19, 726).

Compound with cyanogen $B''Cy_2$ aq. [c. 244°]. Formed by passing cyanogen into an alcoholic solution of the base (Bladin, *B.* 18, 666). Crystals, m. sol. alcohol and ether. Converted by heating with water into NH_3 and two isomeric compounds $C_6H_4N_2O$, one melting at 290°, the other beginning to decompose at 230°–240°. $B''Cy_2$ yields the salts $B''Cy_2HCl$ 1½ aq, $B''Cy_2 \cdot 2HCl$, $B''Cy_2 \cdot H_2PtCl_6$ 2aq, minute needles, ($B''Cy_2$) $_2H_2PtCl_6$ 2aq, and $B''Cy_2 \cdot H_2SO_4$ aq: minute tables.

p-Acetyl derivative $C_6H_4Me(NH_2)(NHAc)$ [1:3:4]. [131°]. Formed by reducing $C_6H_4Me(NO_2)(NHAc)$ with iron and dilute $HOAc$ (Boessneck, *B.* 19, 1757). Plates (from water). Converted by nitrous acid into acetyl-azimido-toluene. On distillation it yields tolylene-acetamidine $C_6H_4Me \begin{smallmatrix} \diagup N \\ \diagdown NH \end{smallmatrix} \gg CMe$ [203°] (Niementowski, *B.* 25, 861).

Di-acetyl derivative $C_6H_4Me(NAc)_2$ [210°]. Formed by boiling the base with Ac_2O (Bistrzycki, *B.* 23, 1878). Thin prisms (from water). Yields $HOAc$ and tolylene-acetamidine on distillation.

Di-propionyl derivative $C_6H_4Me(NH.CO.Et)_2$ [188°]. Formed in like

manner (*B.*). Yields tolylene-propenyl-amine [166°] on distillation.

Benzoyl derivative $C_6H_4Me(NH_2)(NHBz)$ [1:3:4]. [194°]. Formed by reduction of $C_6H_4Me(NO_2)(NHBz)$ with tin and $HClAq$ (Hübner, *A.* 208, 314). Crystals, split up by distillation into water and tolylene-benzamidine [240°].

Di-benzoyl derivative $C_6H_4Me(NHBz)_2$ [264°]. Got by shaking tolylene-*o*-diamine with $BzCl$ and $NaOHAq$ (Hinsberg, *A.* 254, 255), by the action of Bz_2O on the diamine (Bistrzycki, *B.* 23, 1879; 24, 631), and by the action of $BzCl$ on the benzoyl derivative (Hübner, *A.* 208, 314). Needles (from $HOAc$).

o-Chloro-benzoyl derivative $C_6H_4Me(NH_2).NH.CO.C_6H_4Cl$ [153°] (Schreib, *B.* 13, 467). Converted by benzoyl chloride into $C_6H_4Me(NHBz).NH.CO.C_6H_4Cl$ [178°].

Di-cinnamyl derivative $C_6H_4Me(NH.CO.C_6H_5)_2$ [206°]. Formed from tolylene-*o*-diamine and cinnamic anhydride (*B.*). Groups of small needles (from dilute alcohol).

Oxalyl derivative $C_2O_2(NH.C_6H_4.NH_2)_2$ [above 300°]. Obtained by the reduction of $C_2O_2(NH.C_6H_4.NO_2)_2$ (Hinsberg, *B.* 15, 2691). Small needles (from alcohol-ligroin). On fusion it splits up into Aq and $C_6H_4N_2$ [193°].—Salts.— $B''H_2Cl_2$ aq.— $B''H_2PtCl_6$.— $B''H_2SO_4$ 5aq. Colourless needles.

Phthalyl derivatives. The compounds $C_6H_4Me.NH_2.C_6H_4O_2$ [104°] and $C_6H_4Me(NC_6H_4O_2)_2$ [272°] are known (Biedermann, *B.* 10, 1165; Ladenburg, *B.* 10, 1125).

Benzene-sulphonyl derivative $C_6H_4Me(NH_2).NH.SO_3Ph$. The hydrochloride, $B'HCl$, is formed by the action of benzene sulphonic chloride on tolylene-*o*-diamine in benzene (Bistrzycki a. Cybulski, *B.* 24, 633; cf. Lellmann, *A.* 221, 18).

Phenylacetyl derivative $C_6H_4Me(NH_2).NH.CO.CH_2Ph$ [195°]. Formed from tolylene-*o*-diamine and phenylacetyl chloride (*B.* a. *C.*). Needles, v. sol. hot alcohol.

Di-phenylacetyl derivative $C_6H_4Me(NH.CO.CH_2Ph)_2$ [176°]. Needles, insol. ether, v. sol. hot. alcohol.

References.—BROMO-, CHLORO-, and NITRO-TOLYLENE-DIAMINE.

TOLYLENE-DIAMINE SULPHINIC ACID *v.*
DI-AMIDO-TOLUENE SULPHINIC ACID.

TOLYLENE-*o*-DIAMINE SULPHONIC ACID $C_6H_4Me(NH_2)_2.SO_3H$ [1:2:3:5]. Formed by reducing nitro-toluidine sulphonic acid (Nietzki a. Pollini, *B.* 23, 139). Needles. Forms azines with *o*-diketones.

o-Tolylene-m-diamine sulphonic acid $C_6H_3N_2SO_3$ i.e. $C_6H_4Me(NH_2)_2SO_3H$ [1:2:6:4]. S. 0·07 at 14°. Formed from toluene *p*-sulphonic acid by nitration and reduction (Schwanert, *A.* 186, 560; Marckwald, *A.* 274, 349). Prisms, not melted at 280°.— BaA' 4aq.— $HA'HCl$ 2aq.— $HA'HBr$ 2aq.— $HA'HNO_3$ aq: needles, sl. sol. alcohol.— $(HA')_2H_2SO_4$ aq: plates.

Tolylene-*m*-diamine sulphonic acid $C_6H_4Me(NH_2).SO_3H$ [1:2:4:5]. S. 1054 at 10°. Got by reduction of $C_6H_4Me(NO_2)(NH_2).SO_3H$ [1:2:4:5] with $SnCl_4$ (Limpricht a. Foth, *B.* 18, 2185; *A.* 230, 309). Small prisms.— KA' aq.— BaA' 5½ aq.— $HA'HCl$ aq.— $HA'HBr$ aq: prisms.

Tolylene-*m* diamine sulphonic acid $C_6H_4Me(NH_2)_2SO_3H$ [1:2:4:2]. Formed from tolylene-*m*-diamine and fuming H_2SO_4 (Wiesinger, *B.* 7, 464). Small prisms.— NaA' , 4aq.— KA' , aq.— MgA' , 5aq.— CaA' , 6 $\frac{1}{2}$ aq.— SrA' , 7aq.— BaA' , 6 $\frac{1}{2}$ aq.— MnA' , 8aq.

TOLYLENE-DIAMINE THIOSULPHONIC ACID *v.* vol. i. p. 188.

TOLYLENE-BENZAMIDINE *v.* BENZENYL-TOLYLENE-DIAMINE.

TOLYLENE-BENZENYL-DIAMINE *v.* BENZENYL-TOLYLENE-DIAMINE.

***p*-TOLYLENE-BENZYL-DI-AMINE** [1:2:5] $C_6H_4Me(NH_2).NHCH_2Ph$. Got by reducing *p*-nitroso-benzyl-*o*-toluidine by alcoholic ammonium sulphide (Boeddinghaus, *A.* 263, 809).— $B'2HCl$. Needles, sl. sol. alcohol.

TOLYLENE BLUE $C_{15}H_{11}N_3HCl$. Formed by mixing solutions of nitroso-dimethyl-aniline hydrochloride and (1,2,4)-tolylene-*m*-diamine (Witt, *C. J.* 35, 358; *B.* 12, 931). Prisms (containing aq) with coppery lustre, forming blue solutions in water and alcohol. Acids turn the solutions reddish-brown. Alkalies pp. the base as a tarry mass. Tin and $HClAq$ reduce it to the leuco-base, which forms a deliquescent hydrochloride and crystalline $(C_{15}H_{12}N_3)HSnCl_3$. On boiling tolylene-blue with water for some time part is reduced to leuco-tolylene blue and part oxidised to tolylene red $C_{15}H_{11}N_3$. Tolylene blue heated in aqueous solution containing $HOAc$ for 12 hours at 40° forms tolylene violet $C_{15}H_{11}N_3$, characterised by an insoluble sulphate. Hydrated tolylene-violet $C_{15}H_{11}N_3$ aq is a scarlet powder which dissolves in alcohol and in ether, forming solutions with orange fluorescence.

Tolylene red

$[1\frac{3}{4}] C_6H_4(NMe_2) < \overset{N}{N} > C_6H_4Me(NH_2) [4\frac{5}{6}:1]$ (Bernthsen a. Schweitzer, *A.* 236, 332; Andresen, *B.* 19, 2217). Orange-red needles (containing 4aq). Forms a red fluorescent solution in alcohol. Its neutral salts are red, its acid salts are blue. By elimination of NH_3 by the diazo-reaction it is converted into di-methyl-amido-methyl-phenazine.

Isomeride of tolylene red

$[1\frac{3}{4}] C_6H_4(NMe_2) < \overset{N}{N} > C_6H_4Me(NH_2) [4\frac{5}{6}:1]$. Formed from chloro-di-nitro-toluene and di-methyl-*p*-phenylene-diamine and reduction of the product (Witt, *B.* 25, 3008). Coppery needles, sol. warm water.

TOLYLENE-BUTENYL-DIAMINE *v.* BUTENYL-TOLYLENE-DIAMINE.

TOLYLENE-DICARBAMIC ETHER *v.* *i*-TOLYLENE-*m*-DIAMINE.

TOLYLENE DICYANATE $C_6H_4N_2O_2$ *i.e.* [1:2:4] $C_6H_4Me(N:CO)_2$, [94°]. Formed from tolylene-*m*-diamine and $COCl_2$ (Snape, *C. J.* 49, 258). Needles, sol. ether. When heated with phenol at 130° it yields $C_6H_4Me(NH.CO_2Ph)_2$ [147.5°] crystallising in needles.

TOLYLENE-ETHENYL-DIAMINE $C_6H_4N_2$ *i.e.* $C_6H_4Me < \overset{N}{NH} > CMe$. [203°] (Niementowski, *B.* 25, 861). (350°) (Nölting a. Witt, *B.* 17, 81). Formed by boiling (1,3,4)-tolylene-*o*-diamine with $HOAc$ (Ladenburg, *B.* 8, 677) by reducing the acetyl derivative of nitro-*p*-toluidine (Hobbrecker, *B.* 5, 920), and by adding aldehyde to a

solution of tolylene-*o*-diamine in very dilute $HOAc$ (Hinsberg, *B.* 20, 1589). Tables (from water). Forms with acetone and SO_2 the compound $(C_6H_4N_2.C_3H_7O)_2SO_2$ (Boessneck, *B.* 21, 1909).— $B'H_2PtCl_6$.— $B'HNO_3$.

TOLYLENE-ETHENYL-ETHYL-DIAMINE

$C_{11}H_{11}N_2$ *i.e.* $CMe:CH.C.N > CH:CH.C.NEt > CMe$. [166°]. Formed from [1:3:4] $C_6H_4Me(NH_2).NHet$ and Ac_2O (O. Fischer, *B.* 26, 200).

Tolylene-ethenyl-ethyl-diamine

$CMe:CH.C.NEt > CH:CH.C.N > CMe$. [93°]. Got by ethylation of tolylene-ethenyl-diamine (Hübner, *A.* 210, 351). Formed also by the action of aldehyde (2 mols.) on tolylene-*o*-diamine (1 mol.) (Hinsberg, *B.* 20, 1585) and by heating $C_6H_4Me(NO_2)NEtAc$ with zinc-dust and $HOAc$ (Niementowski, *B.* 20, 1884). Needles (containing 3aq). Combines with ethyl iodide, forming $B'EtI$ and $B'EtI_2$ [111°], which yield $B'EtOH$ and $B'Et.PtCl_6$. Salts.— $K'HIaq$ [143°].— $B'HNO_3$ aq. [99°]. Melts at 95° when anhydrous.— $B'C_6H_4N_2O$. Crystals, sl. sol. alcohol.

TOLYLENE-ETHYL-DIAMINE

$CMe:CH.C.NH_2$, $CH:CH.C.NHEt$. [55°]. Formed by reduction of nitro-ethyl-*p*-toluidine (Gattermann, *B.* 18, 1484; Fischer, *B.* 26, 199). White plates, quickly blackened by light and air. Rotates on water.

Reactions.—1. Bisulphide of carbon yields $C_6H_4Me < \overset{N}{NEt} > C.SH$ [139°].—2. Ac_2O forms tolylene-ethenyl-ethyl-diamine [166°].—8. Benzoic aldehyde yields $C_6H_4Me < \overset{N}{NEt} > CPh$; while *o*- and *p*-nitro- and *o*-oxy- benzoic aldehydes from corresponding bodies [170°], [176°], and [78°].

Salts.— $B'HCl$. [176°].— $B'H_2C_2O_4$. [151°].

Tolylene-ethyl-diamine

$C_6H_4Me(NHEt).NH_2$ [1:2:5]. (264° cor.). Formed by reducing nitroso-ethyl-*o*-toluidine (Koch, *A.* 243, 307). Oil, v. sol. ether.— $B'2HCl$. [124°]. Crystals, insol. ether.

Tolylene-ethyl-diamine

$C_6H_4Me(NH_2).NHet$ [1:2:4]. (282° uncor.). Formed by reduction of nitro-ethyl-*p*-toluidine (Nölting a. Stricker, *B.* 19, 549). Oil. Gives the reactions characteristic of *m*-diamines.

Tolylene-di-ethyl-diamine

$C_6H_4Me(NHEt)_2$ [1:3:4]. (265° uncor.). Oil (Hinsberg, *A.* 265, 191). Turns black in air.

Tolylene-di-ethyl-diamine

$C_6H_4Me(NH_2)(NH_2)$ [1:2:5]. (240° i.V.). Formed by reducing nitro-di-ethyl-*o*-toluidine (Bernthsen, *B.* 25, 3138). Oil. $FeCl_3$ slowly gives a purple colour in an aqueous solution of the sulphate. $Na_2S_2O_8$ and $K_2Cr_2O_7$ added to its solution in $HOAc$ slowly ppt. $SO_2.H.S.C_6H_4Me(NEt_2)(NH_2)$ [210°-215°].— $B'H_2SO_4$. Large colourless tables.

DI-TOLYLENE-ETHYLENE-TETRA-AMINE

v. ETHYLENE-DI-TOLYLENE-TETRA-AMINE.

TOLYLENE-DI-ETHYL-DI-THIO-DI-UREA

[1:3:4] $MeC_6H_4(NH.CS.NHEt)_2$. [149°]. Got from ethyl mustard oil (5.5 g.) and tolylene-diamine (8 g.) in alcohol (15 c.c.) (Lellmann, *A.* 221, 23). V. sol. alcohol, more sol. $HOAc$, sl. sol. water. Decomposes when melted into tolylene-thio-urea, $MeC_6H_4(NH)_2CS$, and $CS(NHEt)_2$.

(1.2.4)-Isomeride [225°]. Formed from tolylene-di-thio-di-urea and EtI at 105° (Lussy, B. 8, 668). Crystals.

TOLYLENE-DI-ETHYL-DI-UREA

[1:2.4] $C_6H_4Me(NH.CO.NH.Et)_2$. [175°]. Formed by heating tolylene-urea with EtI at 110° (Lussy, B. 8, 292). Crystals, v. sol. alcohol and ether.

TOLYLENE HYDRATE v. PHENYL-BENZYL-CARBINOL.

DI-TOLYLENE KETONE OXIDE

[1³] $C_6H_4Me \begin{smallmatrix} \diagup O \diagdown \\ \diagdown CO \diagup \end{smallmatrix} C_6H_4Me$ [41]. [166°].

Formed by heating oxytoluic acid with Ac_2O (Weber, B. 25, 1745). White flakes, sol. alcohol and ether.

TOLYLENE MERCAPTAN $C_6H_4Me(SH)_2$ [1:2.4]. *Dithiocrescorcin*. [37°]. (263°) (Klason, B. 20, 355).

Di-tolylene mercaptan

$HS.C_6H_4Me.C_6H_4Me.SH$. [113°]. Formed from the diazo- compound of di-amido-o-ditolylyl by combination with potassium xanthate at 70°–75° and saponification of the resulting oil with alcoholic potash (Leuckart, J. pr. [2] 41, 214). Yellowish plates, v. sol. alcohol and ether.

Methyl ether [118°]. Needles.

TOLYLENE METHENYL-AMIDINE $C_6H_4N_2$

i.e. $C_6H_4Me \begin{smallmatrix} \diagup N \diagdown \\ \diagdown NH \diagup \end{smallmatrix} CH$. [114°]. Formed by boiling from (1,3,4)-tolylene-diamine with formic acid (Ladenburg, B. 10, 1123; O. Fischer, B. 22, 644).— $B'H_2PtCl_6$. Yellow prisms.

TOLYLENE-METHENYL-DIAMINE v.

METHENYL-TOLYLENE-DIAMINE and the preceding body.

TOLYL-METHENYL-METHYL-DIAMINE

$C_6H_4N_2$ i.e. $CH_3.C_6H_4.N \begin{smallmatrix} \diagup CH \diagdown \\ \diagdown CH.NMe \diagup \end{smallmatrix} CH$. [94°].

Formed by heating $C_6H_4(NH_2).NHMe$ with formic acid (O. Fischer, B. 26, 195).

Isomeride $CH_3.C_6H_4.NMe \begin{smallmatrix} \diagup CH \diagdown \\ \diagdown CH.C.N \diagup \end{smallmatrix} CH$. (279°).

Formed by heating tolylene-methenyl-amidine with MeI (O. Fischer, B. 22, 644). Formed also from (1,3,4)-tolylene-diamine and formic aldehyde (Fischer a. Wszinski, B. 25, 2711). Oil.— $B'HI$ aq.— $B'HCl$. Prisms (from HCl aq.).

TOLYLENE-METHYL-DIAMINE

[1:3.4] $C_6H_4Me(NH_2).NHMe$. [44°]. Formed by reducing nitro-methyl-p-toluidine (Gattermann, B. 18, 1487; O. Fischer, B. 26, 194). Formed also by heating methyl-p-amido-toluene-azo-benzene sulphonic acid with $SnCl_2$ and HCl aq (Bamberger a. Wulz, B. 24, 2082). Four-sided tables.

Reactions.—1. *Acetic anhydride* yields $C_6H_4 \begin{smallmatrix} \diagup NH \diagdown \\ \diagdown NMe \diagup \end{smallmatrix} CMe$ [142°].—2. CS_2 reacts, forming $C_6H_4 \begin{smallmatrix} \diagup NH \diagdown \\ \diagdown NMe \diagup \end{smallmatrix} CS$ [194°].—3. *Benzoic aldehyde* forms $C_6H_4 \begin{smallmatrix} \diagup N \diagdown \\ \diagdown NMe \diagup \end{smallmatrix} CPh$ [127°], while* o-nitro- and o-oxy-benzoic aldehyde form corresponding bodies [158°] and [180°].

Salts.— $B'HCl$. [175°–180°]. Plates (from alcohol).— $B'H_2C_2O_4$. [124°].— $B'C_6H_4N_2O_7$. [164°].

Tolylene-di-methyl-diamine

$C_6H_4Me(NMe_2)(NH_2)$ [1:5.2]. [28°]. (270°). Formed by reducing nitroso-di-methyl-m-toluidine (Wurster a. Biedel, B. 19, 1801; 18,

126). Needles or prisms, v. sol. water, alcohol, and ether. Yields toluquinone on oxidation.

Acetyl derivative [158°].—

$B'_2H_2PtCl_6$ 4aq.

Tolylene-di-methyl-diamine

$C_6H_4Me(NMe_2)(NH_2)$ [1:2.5]. [47°]. (240° i.v.). Formed by reducing nitro-di-methyl-o-toluidine (Bernthsen, B. 25, 8134). $FeCl_3$ gives an intense bluish-red colour in neutral solutions. $Na_2S_2O_8$ and $K_2Cr_2O_7$ added to the acetic acid solution ppt. $C_6H_4Me(NMe_2)(NH_2)S.SO_3H$ [c. 240°]. Salt.— $B'_2H_2SO_4$. Needles, v. e. sol. water.

Tolylene-tetra-methyl-diamine

$C_6H_4Me(NMe_2)_2$ [1:2.5]. (c. 260°). Formed by heating the preceding body with MeOH and HCl at 180° (W. a. R.). Liquid. Coloured blue in aqueous solution by $FeCl_3$.

Methylo-iodide $B'MeI$. [160°]. Needles.

Tolylene-tetra-methyl-diamine

$C_6H_4Me(NMe_2)_2$ [1:3.4]. (226°) at 717 mm. Got by methylation (Niementowski, B. 20, 1888). Liquid, v. sl. sol. water. $FeCl_3$ at 40° to 50° gives a reddish-brown colour. HNO_3 added to its solution in H_2SO_4 gives a red colouration.— $B'_2H_2PtCl_6$.— $B'HHgCl_2$.— $B'C_6H_4N_2O_7$. Yellow tables.

Reference.—NITRO-TOLYLENE-TETRA-METHYL-DIAMINE.

TOLYLENE-METHYL-ETHENYL-AMIDINE

$C_{10}H_{12}N_2$ i.e. $CH_3.C_6H_4.N \begin{smallmatrix} \diagup CH \diagdown \\ \diagdown CH.C.NMe \diagup \end{smallmatrix} CMe$. [142°]. Formed, together with $C_{10}H_{12}N_2O$ [163°], which crystallises with 2aq, by reducing the compound $C_6H_4Me(NO_2).NMeAc$ (Niementowski, B. 20, 1878), and by acting on tolylene-methyl-diamine with Ac_2O (O. Fischer, B. 26, 196). Needles (from hot water).— $B'_2H_2PtCl_6$ (dried at 100°). [234°–244°].— $B'HCl$ 3aq.— $B'MeI$. [221°].— $B'MeOH$. [115°–135°].

TOLYLENE-TETRA-METHYL DI-PYRROLE

TETRACARBOXYLIC ACID $C_{22}H_{22}N_2O_8$ i.e. [1:2.4] $C_6H_4Me \begin{smallmatrix} \diagup N \diagdown \\ \diagdown N \begin{smallmatrix} \diagup CO \diagdown \\ \diagdown CO \end{smallmatrix} \end{smallmatrix} C_6H_4Me$. [248°]. Sl. sol. hot alcohol and ether.

Ethyl ether Et_4A' . Formed by heating di-acetyl-succinic ether with tolylene-m-diamine and $HOAc$ at 150° (Knorr, A. 236, 314). Oil.

TOLYLENE-METHYL-THIO-UREA

$CH_3.C_6H_4.NH \begin{smallmatrix} \diagup CS \diagdown \\ \diagdown CS \end{smallmatrix} CH_3$. [194°]. Formed from $CH_3.C_6H_4.NMe$ and CS_2 (Fischer, B. 26, 196). Needles (from alcohol).

TOLYLENE-DI-OXAMIC ACID $C_{11}H_9N_2O_6$ i.e. $C_6H_4Me(NH.CO.CO_2H)_2$ [1:2.4]. Formed, together with the amide, by the action of alcoholic NH_3 on the ether. Crystalline. Very sweet. Decomposed by warm KOH aq into oxalic acid and tolylene-diamine.— AgA' .— PbA' .— BaA' 2aq.

Di-amide $C_6H_4Me(NH.CO.CONH_2)_2$ [1:2.4]. Formed from the ether and alcoholic ammonia (Schiff, A. 268, 3. 8). White powder, m. sol. alcohol.

Ethyl ether [1:2.4]

$C_6H_4Me(NH.CO.CO_2Et)_2$. [180°]. Formed by boiling $C_6H_4Me(NH_2).NH.CO.CO_2Et$ with alcohol and oxalic ether (Schiff a. Vanni, A. 268, 840). Small needles (from ether).

Amide-ether

$C_6H_4Me \begin{smallmatrix} \diagup NH.CO.CO_2Et \diagdown \\ \diagdown NH.CO.CO_2NH_2 \diagup \end{smallmatrix}$ [1:2] [210°]. Formed from $C_6H_4Me(NH_2).NH.CO.CO_2NH_2$ by boiling

with alcohol and oxalic ether (Schiff, *A.* 268, 841).

Amide ether

* $C_6H_5Me \langle \begin{smallmatrix} NH.CO.CONH_2 \\ NH.CO.CO_2Et \end{smallmatrix} \rangle [12] [4]$ [c. 220°]. Got by fusing $C_6H_5Me(NH_2).NH.CO.CO_2Et$ with oxamic ether.

TOLYLENE-OXAMIDE $C_6H_5Me \langle \begin{smallmatrix} NH \\ NH \end{smallmatrix} \rangle C_2O_2$.

[c. 260°]. Formed from (1,2,4)-tolylene-diamine and chloro-glyoxylic ether, and also by heating tolylene-diamine oxalate to 160° (Schiff a. Vanni, *A.* 268, 812).

TOLYLENE-PENTENYL-DIAMINE

$[14] [3] C_6H_5Me \langle \begin{smallmatrix} N \\ NH \end{smallmatrix} \rangle C_5H_9$. [146°]. Formed by reducing the valeryl derivative of nitro-*p*-toluidine (Friederici, *B.* 11, 1974; Hübner, *A.* 209, 365). Prisms (from ligroin), v. e. sol. alcohol.

TOLYLENE - DI - PHENYL - DI - AMIDO-METHYLENE-DIAMINE $C_{20}H_{20}N_4$, i.e.

$C_6H_5Me \langle \begin{smallmatrix} NH \\ NH \end{smallmatrix} \rangle C(NHPh)_2$. [161°]. Formed from $C(NPh)_2$ and (1,3,4)-tolylene-diamine at 130°–149° (Dahm a. Gasiorowski, *B.* 19, 3057). Needles (from benzene), v. sol. alcohol.— $B'3HCl$. [174°].— $B'H_2SO_4$. Plates, v. sol. water and alcohol.

TOLYLENE-PROPENYL-DIAMINE

$C_6H_5Me \langle \begin{smallmatrix} NH \\ N \end{smallmatrix} \rangle C_3H_5$. [166°]. Formed by distilling the dipropionyl derivative of tolylene-*o*-diamine (Bistrzycki, *B.* 23, 1879). Needles, m. sol. water, almost insol. ligroin.

TOLYLENE RED v. TOLYLENE BLUE.

DI-TOLYLENE DISULPHIDE

$CMc:CH.C.S.C.CH:CH$. [116°]. Formed by the action of heat at 200°–250° on tolylene diazo-sulphide $C_6H_5Me \langle \begin{smallmatrix} N \\ S \end{smallmatrix} \rangle N$ [43°], obtained from ethenyl- amido- tolyl mercaptan and HNO_3 (Jacobsen a. Ney, *B.* 22, 911). Conc. H_2SO_4 gives an intense blue colour.

TOLYLENE - DI - THIO - DI - CARBAMIC ETHER [1:3:4] $C_6H_5Me(N:C(SH).OEt)_2$. [120°]. Formed by boiling tolylene-di-thiocarbimide with alcohol (Billeter a. Steiner, *B.* 20, 230). Plates (from benzene). Yields a yellowish-white silver salt.

TOLYLENE - DI - THIOCARBIMIDE [1:2:4] $C_6H_5Me(N.CS)_2$. [56°]. (c. 300°). Formed from tolylene-*m*-diamine and $CSCl_2$, and also by heating tolylene-di-thio-di-urea with conc. $HClAq$ (Billeter a. Steiner, *B.* 18, 3292; 20, 230). Needles. Converted by NH_4Aq into tolylene-di-thio-di-urea [206°], by aniline into di-phenyl-tolylene-di-thio-di-urea [168°]. Copper at 250° produces $C_6H_5MeCy_2$. [141°].

Tolylene-di-thiocarbimide [1:3:4] $C_6H_5Me(N.CS)_2$. [42°]. Formed from an aqueous solution of tolylene-*o*-diamine hydrochloride and SCl_2 in $CHCl_3$ (B. a. S.). Plates. Converted by HCl at 200° into *o*-tolylene-thio-urea.

TOLYLENE-DI-THIO-DIGLYCOLLIC ACID $C_6H_5Me(S.CH_2.CO_2H)_2$. [152°]. Formed from thio-*o*-rocin * $C_6H_5Me(SH)$, [35°], chloro-acetic acid, and $NaOHAq$ (Gabriel, *B.* 12, 1640). Needles, m. sol. hot Aq .

TOLYLENE THIO-UREA $C_6H_5Me \langle \begin{smallmatrix} NH \\ NH \end{smallmatrix} \rangle CS$. Formed from $C_6H_5Me(NH_2HCl)_2$ [1:2:3] and

excess of NH_4SCN by boiling with water, evaporating, and heating to 120° (Lellmann, *A.* 228, 245). Small red crystals (from alcohol). Does not melt below 326°; may be sublimed. Insol. water, sl. sol. alcohol, dissolved by warm $NaOH$; re-ppd. by HCl . When boiled with lead acetate and excess of $NaOH$, no PbS is formed.

Tolylene - thio - urea $C_6H_5Me \langle \begin{smallmatrix} NH \\ NH \end{smallmatrix} \rangle CS$.

[284°]. Formed by heating (1,3,4)-tolylene-*o*-diamine sulphocyanide at 180° (Lellmann, *A.* 221, 10). Formed also by the action of alcoholic NH_3 on *o*-tolylene di-thiocarbimide (Billeter a. Steiner, *B.* 20, 231). Silvery plates, sol. alcohol, $HOAc$, and cold $NaOHAq$, sl. sol. water and $CHCl_3$.

***m*-Tolylene - thio - urea** $C_6H_5Me \langle \begin{smallmatrix} NH \\ NH \end{smallmatrix} \rangle CS$.

[149°]. Formed from (1,2,4)-tolylene-diamine and alcoholic CS_2 (Lussy, *B.* 8, 293). Crystalline powder, v. e. sol. alcohol.

***m*-Tolylene-di-thio-di-urea**

[1:2:4] $C_6H_5Me(NH.CS.NH_2)_2$. [218°] (L.); [206°] (B. a. S.). Formed by heating tolylene-*m*-diamine sulphocyanide (Lussy, *B.* 7, 1265; Gebhardt, *B.* 17, 3046; Billeter a. Steiner, *B.* 18, 3293; 20, 228). Crystalline powder, insol. water and ether, nearly insol. alcohol, m. sol. hot $HOAc$.

TOLYLENE-TOLENYL-AMIDINE $C_{11}H_{11}N_3$,

i.e. $C_6H_5Me \langle \begin{smallmatrix} NH \\ N \end{smallmatrix} \rangle C.C_6H_5Me$. Formed by reducing [1:4] $C_6H_5Me.CO.NH.C_6H_5(NO_2)Me$ [4:3:1] (Hübner, *A.* 210, 331). Needles, sl. sol. water.— $B'HCl$.— $B'HNO_3$.— $B'H_2SO_4$. Crystals, sl. sol. water.

TOLYLENE - DI - *p*-TOLYL - DI - AMIDO-METHYLENE-DIAMINE $C_{22}H_{22}N_4$, i.e.

$C_6H_5Me \langle \begin{smallmatrix} NH \\ NH \end{smallmatrix} \rangle C(NH.C_6H_4Me)_2$. [196°].

Formed by heating $C(NC_6H_4Me)_2$ with (1,3,4)-tolylene-diamine (Dahm a. Gasiorowski, *B.* 19, 3059). Needles (from alcohol).— $B'3HCl$. [143°]. Deliquescent needles, v. sol. water.

TOLYLENE-TOLYL-DIAMINE $C_{11}H_{11}N_2$, i.e.

[1:3:4] $C_6H_5Me(NH_2)NHC_6H_4Me$ [1:4]. *Amido-di-*p*-tolyl-amine*. [109°]. Formed by reducing nitro-di-*p*-tolylamine (O. Fischer, *B.* 23, 3798; 26, 187). Prisms (from ligroin), turning brownish-red in air. H_2SO_4 forms a blue solution changing to green. $FeCl_3$ forms $C_{22}H_{22}N_2O$ [188°] crystallising in red plates, yielding $B'H_2PtCl_4$. Boiling with acetic anhydride and sodium acetate produces $C_6H_5 \langle \begin{smallmatrix} N(C_6H_5) \\ N \end{smallmatrix} \rangle CMe$ [95°], which forms $B'H_2PtCl_4$. Benzoic aldehyde forms $C_6H_5 \langle \begin{smallmatrix} N(C_6H_5) \\ NH \end{smallmatrix} \rangle CHPh$ [156°], which yields $(C_{21}H_{22}N_2)_2H_2PtCl_4$ and $C_{21}H_{22}N_2.HAuCl_4$.

Salts.— $B'H_2C_2O_4$. Nearly insol. cold Aq .— $B'C_6H_5N_2O_2$. Brownish-red crystals.

Acetyl derivative [126°]. Prisms.

Tolylene-*p*-tolyl-diamine

[1:4:3] $C_6H_5Me(NH_2).NHC_6H_4Me$ [1:4]. [107°]. Formed from toluene-azo-toluene or *s*-di-*p*-tolyl-hydrazine (hydrazo-toluene) in alcoholic solution by the action of $SnCl_4$ and HCl (Täuber, *B.* 25, 1022; cf. Melms, *B.* 8, 554; Goldschmidt, *B.* 11, 1626). Plates, v. e. sol. alcohol. $NaNO_2$ colours its solution in H_2SO_4 deep blue (?). Benzoic aldehyde reacts, forming

$C_6H_5 \left\langle \begin{smallmatrix} N(C_6H_5) \\ N \end{smallmatrix} \right\rangle CPh$ [165°] (cf. Lellmann, *B.* 15, 832). Benzil in alcohol and HCl forms $C_6H_5N_2O$ [173°]. Ethyl nitrite and H_2SO_4 added to its alcoholic solution form the azimide $C_6H_5 \left\langle \begin{smallmatrix} N(C_6H_5) \\ N \end{smallmatrix} \right\rangle N$ [93°]. On oxidation together with *p*-toluidine it forms the ditoluide of amido-toluquinone (Green, *C. J.* 63, 1408).

Tolylene-di-*p*-tolyl-diamine

[1:2:5] $C_6H_5Me(NHC_6H_4)_2$. [113°]. Formed by heating hydrotoluquinone (40 g.) with *p*-toluidine (160 g.) and $ZnCl_2$ (80 g.) to 200°–280° for 5 hours (Green, *C. J.* 63, 1408). Plates, sol. HOAc, insol. water.

TOLYLENE-*p*-TOLYL-GUANIDINE

$C_6H_5Me \left\langle \begin{smallmatrix} NH \\ NH \end{smallmatrix} \right\rangle C:NC_6H_4$. [198°]. Formed from tolylene-*o*-diamine and $C(NC_6H_4)_2$ (Keller, *B.* 24, 2518). Prisms (from alcohol), or tablets (from benzene). Phenyl cyanate forms the compound $C_6H_5 \left\langle \begin{smallmatrix} N \\ N \end{smallmatrix} \right\rangle C:NC_6H_4 \begin{smallmatrix} CO \\ CO \end{smallmatrix} \right\rangle NPh$ [233°], crystallising from hot alcohol in needles. — $B'HCl$. — $B'_2H_2PtCl_6$. — $B'_2H_2SO_4$, 5aq. Needles, sl. sol. cold water.

Acetyl derivative $C_6H_5 \left\langle \begin{smallmatrix} NAc \\ NH \end{smallmatrix} \right\rangle C:NC_6H_4$.

[149°]. Needles, v. sol. alcohol.

Di-benzoyl derivative [201°]. Needles.

Nitrosamine $C_6H_5N_2H(NO):C:NC_6H_4$. [c. 140°]. Decomposed on fusion.

TOLYLENE-*p*-TOLYL-THIO-UREA

$CH:CH.C.N(C_6H_4) \left\langle \begin{smallmatrix} NH \\ NH \end{smallmatrix} \right\rangle CS$. [270°]. Formed from $CMe:CH.C.NH$ tolylene-*o*-diamine and CS_2 in alcohol (Fischer a. Sieder, *B.* 23, 3799). Prisms, insol. water, sl. sol. ligroin. Conc. H_2SO_4 forms a green solution.

TOLYLENE-UREA $C_6H_5N_2O$ i.e.

$[1:3:4] C_6H_5Me \left\langle \begin{smallmatrix} NH \\ NH \end{smallmatrix} \right\rangle CO$. [292°]. Formed by heating tolylene-*o*-diamine with urea and got also by the action of $HClAq$ at 140° on $C_6H_5Me \left\langle \begin{smallmatrix} NH \\ N \end{smallmatrix} \right\rangle COEt$ [163°], which is formed by the action of $HN:C(OEt)$, on tolylene-*o*-diamine hydrochloride (Sandmeyer, *B.* 19, 2651). Formed also by heating $C_6H_5(NH_2).NH.CO.NPh_2$ (Lellmann a. Bonhöffer, *B.* 20, 2124) or the compound $C_6H_5(NH_2).NH.CO.NHPh$ (Leuckart, *J. pr.* [2] 41, 324, who states that it melts above 300°), and by heating tolylene-*o*-diamine in benzene with $COCl_2$ in toluene in sealed tubes at 100° (Hartmann, *B.* 23, 1048). Needles, sl. sol. hot water. — $B'HCl$: prisms.

TOLYLENE-DI-UREA $C_6H_5N_2O_2$ i.e.

[1:3:4] $C_6H_5Me(NH.CO.NH_2)_2$. [282°]. Got from tolylene-diamine hydrochloride and potassium cyanate in aqueous solution (Lellmann, *A.* 221, 14). Needles, sl. sol. water and chloroform, sol. alcohol and hot conc. HCl; v. sol. HOAc.

Tolylene-di-urea $C_6H_5N_2O_2$ i.e.

[1:2:4] $C_6H_5Me(NH.CO.NH_2)_2$. [220°]. Formed from tolylene-*m*-diamine sulphate and $KCyO$ (Strauss, *A.* 148, 157). Formed also from tolylene cyanate and ammonia (Lussy, *B.* 8, 291). Scales, sl. sol. alcohol and hot water. — B'^2HCl .

TOLYLENE-VIOLET v. TOLYLENE BLUE.

s-DI-TOLYL-ETHANE

$C_6H_5Me.CH_2.CH_2.C_6H_5Me$. (296°). Formed from

$C_6H_5Me.CH_2Cl$ and sodium (Vollrath, *Z.* 1866, 489). Oil.

u-Di-*p*-tolyl-ethane $CH_3.CH(C_6H_5Me)_2$. (295°). S.G. $\frac{4}{4}$ 974. Formed by shaking paraldehyde with toluene and H_2SO_4 at 0° (O. Fischer, *B.* 7, 1191). Formed also by heating di-*a*-tolyl-propionic acid with lime (Haiss, *B.* 15, 1476) and by the action of ethyldiene chloride and $AlCl_3$ on toluene (Anschtütz, *B.* 18, 664; *A.* 235, 315). Oil. Yields tolyl-benzoic acid and di-tolyl ketone on oxidation.

s-*mp*-Di-tolyl-ethane $C_6H_4(C_6H_5)_2$. (297°–300°). Formed from ethylene bromide, toluene, and $AlCl_3$ (Friedel a. Balsohn, *Bl.* [2] 35, 52; *A. Ch.* [6] 1, 487). Yields isophthalic and terephthalic acids on oxidation.

References.—AMIDO-, CHLORO-, TRI-CHLORO-, DI-NITRO-, and OXY-TOLYL-, ETHANES.

TOLYL ETHER v. DI-TOLYL OXIDE.

o-TOLYL-ETHYL ALCOHOL.

Hexa

hydride $CH_2 \left\langle \begin{smallmatrix} CH_2.CHMe \\ CH_2.CH_2 \end{smallmatrix} \right\rangle CH.CHMe.OH$.

(195°–200°). Formed, together with the tetrahydride $CH_2 \left\langle \begin{smallmatrix} CH_2.CMe \\ CH_2.CH_2 \end{smallmatrix} \right\rangle C.CHMe.OH$ (142° at 50 mm.) by reducing $C_6H_5Me.CO.CH_3$ in moist ethereal solution by sodium (Kipping a. Perkin, jun., *C. J.* 57, 22). Oil. Yields an acetyl derivative (204°–208°).

p-TOLYL-ETHYL-*m*-AMIDO-PHENOL.

Ethyl derivative $C_6H_4.NEt.C_6H_4.OEt$. Formed from $C_6H_5.NH.C_6H_4.OH$, potash, and EtI (Hatschek a. Zega, *J. pr.* [2] 33, 217). Oil.

p-Tolyl-ethyl-*p*-amido-phenol. Ethyl derivative $C_6H_4.NO$ i.e. $C_6H_4.NEt.C_6H_4.OEt$. (c. 340°). From $C_6H_5.NH.C_6H_4.OH$, potash, and EtI (H. a. Z.). Oil.

TOLYL-ETHYL-AMINE v. ETHYL-TOLUIDINE.

Di-tolyl-ethyl-amine $(C_6H_5Me)_2.NEt$. (255°–260° at 20 mm.). Formed by heating di-*p*-tolyl-amine with $EtOH$ and HCl at 250°–280° (Girard, *Bl.* [2] 24, 120). Oil.

o-TOLYL ETHYL CARBONATE $C_{10}H_{12}O_2$ i.e.

[1:2] $C_6H_5Me.O.CO.OEt$. (236°). Formed from sodium *o*-cresol and $ClCO_2Et$ (Bender, *B.* 13, 700). Oil.

m-Tolyl ethyl carbonate. (246°). Formed in like manner from *m*-cresol. Oil.

p-Tolyl ethyl carbonate. (245°). Oil. By long heating at 300° it yields di-*p*-tolyl carbonate and di-ethyl carbonate (Bender, *B.* 19, 2268).

DI-*p*-TOLYL-ETHYLENE $C_{10}H_{12}$ i.e.

$C_6H_5Me.CH:CH.C_6H_5Me$. Di-methyl-stilbene. [179°]. (above 300°). Formed by distilling $(C_6H_5Me).CH.CCl_3$ with zinc-dust (Goldschmiedt a. Hepp, *B.* 6, 1504; Elbs a. Förster, *J. pr.* [2] 39, 300), and by heating di-*p*-tolyl fumarate, CO_2 being evolved (Anschtütz, *B.* 18, 1948). Plates, v. sol. $CHCl_3$. Yields a dibromide [204°].

u-Di-tolyl-ethylene $CH_2:C(C_6H_5Me)_2$. (305°). Formed by the action of alcoholic potash on $CH_2Cl.CH(C_6H_5)_2$ (Hepp, *B.* 7, 1418). Oil. Yields di-tolyl-ketone [94°] on oxidation.

Tetra-tolyl-ethylene $C_{24}H_{20}$ i.e.

$(C_6H_5)_2C:C(C_6H_5)_2$. [215°]. A product of the action of chloroform and $AlCl_3$ on toluene (Schwarz, *B.* 14, 1529). Plates, with greenish-yellow fluorescence, sol. benzene.

References.—Bromo- and Di-CHLORO-TOLYL-ETHYLENE.

o-TOLYL-ETHYLENE-DIAMINE

$C_6H_4NH_2CH_2CH_2NH_2$. (c. 267°). Formed from *o*-tolylamido-ethyl-phthalimide and HCl (Newman, *B.* 24, 2194). Sol. water and alcohol.— $B''2HCl$. [168°–173°].— $B''2C_6H_5N_3O_2$. [148°]. Green needles.

Di-benzoyl derivative [164.5°]. Needles.

p-Tolyl-ethylene-diamine. Formed in like manner (N.). Liquid.— $B''2HCl$. [218°].— $B''H_2PtCl_6$. Yellowish plates.

Di-acetyl derivative [107°]. Needles.

Di-benzoyl derivative [161°]. Cubes.

Di-o-tolyl-ethylene-diamine $C_{18}H_{20}N_2$ i.e. $C_6H_4NH_2CH_2CH_2NHC_6H_4$. [71°]. S. 3 at 100°. S. (cold alcohol) 9. S. (ether) 14. Formed by the action of *o*-toluidine on ethylene bromide in presence of Na_2CO_3 (Bischoff, *B.* 23, 1982, 2031; 25, 3257; cf. Mauthner a. Suida, *M.* 7, 230; Colson, *Bl.* [2] 48, 799). Plates (from ligroin), v. sol. alcohol. Yields indole on heating with zinc-dust. $CH_3Cl.OO.H$ and $NaOAc$ from di-tolyl-pyrazine hexahydride [154°].— $B''2HCl$.— $B''H_2PtCl_6$.— $B''H_2SO_4$ (dried at 100°).— $B''2HBr$. [222°]. S. 3 at 100°.

Acetyl derivative $C_2H_5(NAc.C_6H_4)_2$. [153°].

Bromo-acetyl derivative $C_6H_4(NC_2H_4.CO.CH_2Br)_2$. [205°]. Sl. sol. cold $HOAc$ and ligroin.

Bromo-propionyl derivative $C_{22}H_{26}N_2Br_2O_2$. [181°].

Bromo-n-butyryl derivative $(C_2H_5)_3NBr.O_2C.C_6H_4$ (from benzene). [190°].

Bromo-isobutyryl derivatives $C_6H_4NH_2CH_2NC_2H_4.CO.CBrMe_2$ [137°] and $C_{21}H_{30}N_2Br_2O_2$. [173°].

Di-p-tolyl-ethylene-diamine [97.5°]. Formed by heating *p*-toluidine with ethylene bromide at 150° (Gretillat, *M.* S. [3] 3, 383; Bischoff, *B.* 25, 3260). Crystals, v. e. sol. alcohol.—Hydrobromide [255°].

Acetyl derivative $C_2H_5(NAc.C_6H_4)_2$. [139°].

Bromo-acetyl derivative $C_{20}H_{22}N_2Br_2O_2$. [196°].

Bromo-propionyl derivative. [182°].

Bromo-n-butyryl derivative $C_{24}H_{30}N_2Br_2O_2$. [125°].

Bromo-isobutyryl derivative $C_{24}H_{30}N_2Br_2O_2$. [175°].

Di-o-tolyl-di-ethylene-diamine $C_{18}H_{22}N_2$. [171°]. Formed, together with di-*o*-tolyl-ethylene-diamine, by heating *o*-toluidine with $C_2H_4Br_2$ (M. a. S.). Needles, sl. sol. alcohol. Forms indole when distilled with zinc-dust.

Di-p-tolyl-di-ethylene-diamine [190°]. (360°). Formed by heating $C_2H_4Cl.OH$ with *p*-toluidine at 220° (Wurtz, *A. Suppl.* 7, 94; Demole, *A.* 173, 138). Prisms, v. sl. sol. alcohol.— $B''H_2PtCl_6$.

Tri-p-tolyl-tri-ethylene-triamine

$N_3(C_6H_4)_3$. [186°]. Formed by heating *p*-toluidine with $C_2H_4Br_2$ (G.). Needles, v. sl. sol. alcohol. Is perhaps identical with the preceding body. Its hydrochloride melts at 189°.

Reference.—NITRO-DI-TOLYL-ETHYLENE-DIAMINE.

p-TOLYL ETHYLENE ETHYL DIOXIDE

$C_6H_4Me.O.CH_2CH_2.OEt$. (244°). Formed from $C_6H_4O.C_2H_5Br$ and alcoholic potash (Schreiber, *B.* 24, 195).

DI-p-TOLYL ETHYLENE DIKETONE

$C_6H_4O_2$ i.e. $C_2H_4(CO.C_6H_4Me)_2$. *Di-tolyl-ethane*. [159°]. Formed by the action of succinyl chloride and $AlCl_3$ on toluene (Hollemann, *R. T. C.* 6, 70; Claus, *B.* 20, 1377). Needles, v. sl. sol. cold alcohol, insol. alkalis. $AcCl$ converts it into di-*p*-tolyl-furfuran $C_{18}H_{16}O$ [164°]. Ammonium acetate and $HOAc$ on boiling form di-*p*-tolyl-pyrrole [197°]. P_2S_5 forms di-*p*-tolyl-thiophene [171°].

DI-p-TOLYL-ETHYLENE-DI-METHYL-DIAMINE $C_{18}H_{22}N_2$ i.e. $C_2H_4(NMe.C_6H_4Me)_2$. [80°]. Formed by boiling its di-methyl-di-bromide with NH_3Aq (Hübner, *A.* 224, 337). Tables or prisms (from alcohol), v. sl. sol. water.— $B''H_2HgCl_2$. [190°].— $B''H_2PtCl_6$. Orange-yellow powder.

Methyl-iodide $B''MeI$. Needles. Decomposed at 100°. M. sol. hot water.

Methyl-bromide $B''2MeBr$. Formed by heating di-methyl-*p*-toluidine with $C_2H_4Br_2$ at 105° for some days. Yields $B''Me_2HgCl_2$ [159°–162°], $B''Me_2SnCl_4$, $B''Me_2PtCl_6$, and $B''2C_6H_5MeN_2O_2$, [197°], which crystallises from alcohol.

TOLYL ETHYLENE OXIDE o. ETHYLENE

ETHER OF CRESOL.

DI-p-TOLYL ETHYLENE DISULPHONE

$(C_6H_4SO_2)_2C_2H_4$. [201°]. Made by boiling sodium toluene *p*-sulphinate with $C_2H_4Br_2$ and alcohol (Otto, *J. pr.* [2] 30, 354; 40, 534). Got also by boiling the same salt with $CH_3.CCl_2.CO_2Na$. Needles or plates. Dilute $KOHAq$ converts it into toluene sulphinic acid and $C_6H_4SO_2.C_6H_4OH$ [55°], which yields $C_6H_4SO_2.C_6H_4O_2$ [79°], $C_6H_4SO_2.C_6H_4I$ [100°], $C_6H_4SO_2.C_6H_4OBz$ [176°] and $(C_6H_4SO_2.C_6H_4)_2S$ [150°–160°]. Ammonia forms $(C_6H_4SO_2.C_6H_4)_2NH$, which yields a hydrochloride [201°].

DI-p-TOLYL-ETHYLENE-UREA

$CH_2N(C_6H_4)_2CO$. [223°]. Formed from di-*p*-tolyl-ethylene-diamine and $COCl_2$ (Michler a. Keller, *B.* 14, 2184). Needles.

p-TOLYL-DI-ETHYL-PHOSPHINE

$C_6H_4.PEt_2$. (240°). Formed from $C_6H_4.PCl_2$ and $ZnEt_2$ (Czimatiss, *B.* 15, 2016). Liquid.— $B''MeI$. [137°].— $B''Me_2PtCl_6$. Yellow plates.

p-TOLYL ETHYL SULPHONE

$C_6H_4.SO_2.C_2H_5$. [56°]. Formed by oxidation of $C_6H_4.SEt$ and by the action of $EtBr$ on sodium toluene *p*-sulphinate (Otto, *B.* 13, 1276; 18, 161). Formed also by warming the acid $C_6H_4.SO_2.CHMe.CO_2H$ with $KOHAq$. Trimetric plates; $a:b:c = .526:1: .721$. Sol. alcohol and ether.

p-TOLYL ETHYL SULPHONE a-CARB-OXYLIC ACID $C_6H_4.SO_2.CHMe.CO_2H$. *Tolyl-sulphono-propionic acid*. [37°]. Formed by heating $C_6H_4SO_2Na$ with $CH_3.CHBr.CO_2Et$ and alcohols at 150° and saponifying the product (Otto, *J. pr.* [2] 40, 555). Crystals (from alcohol), converted by Cl into $CH_3.CHCl.SO_2.C_6H_4$.

TOLYL ETHYL DISULPHOXIDE v. Ethyl ether of Toluene thiosulphonic acid.

TOLYL ETHYL THIOBIURET $C_{11}H_{13}N_3S$. [134°]. Formed from tolyl-thiobiuret, alcohol, aqueous NH_3 , and EtI (Tursini, *B.* 17, 585). Needles (from alcohol).

o-TOLYL-ETHYL-THIOSEMICARBAZIDE

$C_6H_4NH.NH.CS.NH.Et$. [180°]. Formed *o*-tolyl-

hydrazine and an alcoholic solution of ethylthiocarbimide (Dixon, *C. J.* 57, 262). Needles, v. sl. sol. cold water. CuSO_4 colours its alcoholic solution deep blue.

TOLYL ETHYL DI-THIO-CARBONATES

$\text{CS}(\text{OEt})_2 \cdot \text{S} \cdot \text{C}_6\text{H}_4\text{Me}$. The *o*-, *m*-, and *p*-compounds formed by the action of potassium xanthate on cold solutions of *o*-, *m*-, and *p*-diazotoluene chloride are oils (Leuckart, *J. pr.* [2] 41, 188). They are converted into tolyl mercaptans by boiling with alcoholic potash.

o-TOLYL-ETHYL-THIO-UREA

$\text{CS}(\text{NHEt})_2 \cdot \text{NHC}_6\text{H}_4\text{Me}$. [84°]. Formed from *o*-tolylthiocarbimide and ethylamine (Staats, *B.* 13, 136). Prisms, insol. water, sol. alcohol and ether.

p-Tolyl-ethyl-thio-urea [96°]. Formed in like manner (Weith, *B.* 8, 1530). Tables, v. sol. hot water.

o-Tolyl-di-ethyl-thio-urea $\text{CS}(\text{NEt}_2)_2 \cdot \text{NHC}_6\text{H}_4$. [102°]. Formed from *o*-tolylthiocarbimide and NHEt_2 (Gebhardt, *B.* 17, 3038). Needles or prisms.

p-TOLYL-ETHYL-TOLUTRIAZINE DIHY-

DRIDE $\text{C}_{11}\text{H}_{11}\text{N}_3$, i.e. $\text{C}_6\text{H}_4\text{Me} \cdot \text{N} \cdot \text{CHEt} \cdot \text{N} \cdot \text{N} \cdot \text{C}_6\text{H}_4\text{Me}$. [168°]. Formed by heating toluene-azo-toluidine with propionic aldehyde at 140° (Goldschmidt a. Poltzer, *B.* 24, 1009). Needles (from hot benzene). — B^1HCl . [96°]. — Platinochloride [221°]. Small yellow needles.

p-TOLYL-ETHYL-UREA

$\text{C}_{10}\text{H}_{11}\text{N}_2\text{O}$ i.e. $\text{NHC}_6\text{H}_4\text{CO} \cdot \text{NHEt}$. Formed from *p*-toluidine and ethyl cyanate (Sell, *A.* 126, 162). Crystals, insol. water, v. e. sol. alcohol.

DI-*o*-TOLYL-FORMAMIDINE

$\text{C}_{11}\text{H}_{11}\text{N}_2$ i.e. $\text{NHC}_6\text{H}_4\text{CH} \cdot \text{NC}_6\text{H}_4$. [151°]. Formed by boiling the formyl derivative of *o*-toluidine for a long time, or by heating it with *o*-toluidine and PCl_5 (Ladenburg, *B.* 10, 1260). Formed also by distilling the thioformyl derivative of *o*-toluidine *in vacuo* (Senier, *C. J.* 47, 762). Prisms (from alcohol), insol. dilute NaOHaq . Yields crystalline $\text{C}_{11}\text{C}_6\text{H}_4\text{N}_2\text{Br}_2$. — $\text{B}^1\text{H}_2\text{PtCl}_6$.

Di-*m*-tolyl-formamidine

$\text{NHC}_6\text{H}_4\text{CH} \cdot \text{NC}_6\text{H}_4$. [123°]. Formed by boiling *m*-toluidine with formic acid (Niemetowski, *B.* 20, 1893). Needles or plates, insol. water. Br in CS_2 yields crystalline $\text{NHC}_6\text{H}_4\text{CHBr} \cdot \text{NBrC}_6\text{H}_4$. — B^1HCl . [214°]. — $\text{B}^1\text{H}_2\text{PtCl}_6$. — $\text{B}^1\text{C}_6\text{H}_4\text{N}_2\text{O}_7$. Yellow needles.

Di-*p*-tolyl-formamidine

[141°]. Formed by distilling $\text{C}_6\text{H}_5\text{NH} \cdot \text{CHS}$ *in vacuo* (Senier, *C. J.* 47, 767; *B.* 18, 2296). Prisms. — $\text{B}^1\text{H}_2\text{PtCl}_6$.

DI-*p*-TOLYL-FURFURANE

$\text{C}_{16}\text{H}_{11}\text{O}$ i.e. $\text{CH} \cdot \text{C}(\text{C}_6\text{H}_4) > \text{O}$. [164°]. Formed by the action of $\text{CH} \cdot \text{C}(\text{C}_6\text{H}_4) > \text{O}$. [164°]. Formed by the action of AcCl on $\text{C}_6\text{H}_5(\text{CO} \cdot \text{C}_6\text{H}_4)_2$ (Holleman, *R. T. C.* 6, 72). Small plates, converted by P_2S_5 into di-tolylthiophene, and by ammonium acetate into di-tolyl-pyrrole.

p-TOLYL-GLYOXAL

$\text{C}_6\text{H}_4\text{Me} \cdot \text{CO} \cdot \text{CHO}$. [102°]. Formed from the oxim by dissolving in aqueous NaHSO_3 , stirring the crystalline mass with alcohol and a little HOAc , filtering, and boiling with dilute H_2SO_4 (Müller a. Pechmann, *B.* 22, 2556). Needles (from hot water), v. sol. alcohol. Reduces cold ammoniacal AgNO_3 , but not Fehling's solution. When shaken with benzene (containing thiophene) and H_2SO_4 , it colours the benzene green. Yields *p*-tolylglyoxylic acid and *p*-toluic acid on oxidation.

Phenyl hydrazide

$\text{C}_6\text{H}_5 \cdot \text{C}(\text{N} \cdot \text{HPh}) \cdot \text{CH}(\text{N} \cdot \text{HPh})$. [145°]. Yellow needles (from dilute alcohol).

Oxim $\text{C}_6\text{H}_5 \cdot \text{CO} \cdot \text{CH} \cdot \text{NOH}$. Tollyl nitroso-methyl ketone. [100°]. Formed from tolyl methyl ketone, amyl nitrite and NaOEt . Needles (from benzene).

Acetyl derivative of the syn-oxim

$\text{C}_6\text{H}_5 \cdot \text{CO} \cdot \text{CH} \cdot \text{NOAc}$ [68°]. From the oxim and Ac_2O (Söderbaum, *B.* 25, 3461). Tables (from MeOH). Cold NaOHaq splits it up into NaCy and *p*-toluic acid. Conc. H_2SO_4 acts in like manner. Ac_2O at 100° forms $\text{C}_6\text{H}_5 \cdot \text{CO} \cdot \text{CN}$ [52°], whence boiling NaOHaq forms *p*-toluic acid.

Acetyl derivative of the anti-oxim

$\text{C}_6\text{H}_5 \cdot \text{C}(\text{OH})_2 \cdot \text{CH} \cdot \text{NOAc}$. [148°]. From the oxim and AcCl at 0°, followed by water. Cold NaOHaq forms $\text{C}_6\text{H}_5 \cdot \text{CH}(\text{OH}) \cdot \text{CO} \cdot \text{H}$ [146°], v. sol. ether. Conc. H_2SO_4 converts this acetyl anti-oxim into the oxim. Converted by KCy dissolved in dilute alcohol into *p*-tolyl-formoin $\text{C}_6\text{H}_5 \cdot \text{CO} \cdot \text{CH}(\text{OH}) \cdot \text{CO} \cdot \text{CO} \cdot \text{C}_6\text{H}_5$ [161°] (Söderbaum, *B.* 25, 3473).

p-TOLYL-GLYOXALINE

$\text{C}_{10}\text{H}_9\text{N}_3$ i.e. $\text{C}_6\text{H}_4\text{N} < \text{CH} \cdot \text{CH} > \text{CH} \cdot \text{N}$. (285°). Got by warming

$\text{C}_6\text{H}_4\text{N} < \text{CH} = \text{CH} > \text{CH} > \text{N}$ with dilute HNO_3 (Marckwald, *B.* 25, 2365). Pale-yellow crystals, sl. sol. water. Smells like mushrooms. — $\text{B}^1\text{H}_2\text{PtCl}_6$. — B^1AgNO_3 . — Picrate. [179°]. Golden needles.

p-TOLYL-GLYOXALYL MERCAPTAN

$\text{C}_6\text{H}_4\text{N} < \text{CH} = \text{CH} > \text{N}$. [205°]. Got by action of boiling HClaq on the product of the action of amido-acetal on *p*-tolylthiocarbimide (Marckwald, *B.* 25, 2363). Silvery leaflets, m. sol. hot water. Yields $(\text{C}_{10}\text{H}_9\text{N}_2\text{S})_2 \cdot \text{PtCl}_6$. Mel in alcohol forms $(\text{C}_{10}\text{H}_9\text{MeN}_2\text{S})\text{HI}$ [95°], which yields the base $\text{C}_6\text{H}_4\text{N} < \text{CH} = \text{CH} > \text{N}(\text{SMe})$ [90°], which forms a picrate [140°].

p-TOLYL-GLYOXYLIC ACID

$\text{C}_6\text{H}_4\text{Me} \cdot \text{CO} \cdot \text{CO}_2\text{H}$. [97°]. Formed by the action of AlCl_3 on a mixture of toluene and $\text{Cl} \cdot \text{CO} \cdot \text{CO}_2\text{C}_6\text{H}_5$ (Roser, *B.* 14, 1760). Formed also by oxidising *p*-tolyl methyl ketone with cold alkaline K_2FeCy_6 (Buchka a. Irish, *B.* 20, 1762, 2213). Needles (from ligroin), sl. sol. hot water, v. sol. alcohol and ether. Yields *p*-toluic and terephthalic acids on oxidation. Benzene (containing thiophene) when shaken with tolyl-glyoxylic acid and H_2SO_4 , is turned red, and finally bluish-violet.

Salts. — KA' . — $\text{NaA}' \frac{1}{2}\text{aq}$ (Claus a. Krosenberg, *B.* 20, 2048). — BaA'_2 . — $\text{BaA}'_2 \cdot 8\text{aq}$. — $\text{CaA}'_2 \cdot \text{aq}$. — AgA' . Needles, v. sol. hot water.

Ethyl ether Eta'

[260°–270°].

Amide $\text{C}_6\text{H}_4\text{NO}_2$

[160°]. Prisms.

Phenyl hydrazide

DI-*o*-TOLYL-GUANIDINE $\text{C}_{11}\text{H}_{11}\text{N}_3$ i.e. $\text{C}(\text{NH})(\text{NHC}_6\text{H}_4)_2$. [179°]. Formed by the action of NH_3 , lead acetate, and KOHAq on di-*o*-tolylthio-urea (Berger, *B.* 12, 1855). Crystals, sol. ether. Cyanogen passed into its alcoholic solution forms the dicyanide $\text{C}_{11}\text{H}_{11}\text{N}_6$ [174°] which is converted by HCl into the oxaly derivative $\text{C}_{11}\text{H}_{11}\text{N}_6\text{O}_2$ [207°], whence boiling with alcoholic HCl forms $\text{CO} < \text{NC}_6\text{H}_4 \cdot \text{CO} > \text{NC}_6\text{H}_4 \cdot \text{CO}$ [214°]. The dicyanide is converted by boiling with ani-

line into $C_{10}H_7N_3$, which yields crystalline $B'HCl$ aq.— $B'_2H_2PtCl_6$: yellow pp.

Di-*p*-tolyl-guanidine $NH.C(NHC_6H_4)_2$. [168°]. Formed by passing cyanogen chloride into fused *p*-toluidine (W. Wilson, *C. J.* 3, 154; A. G. Perkin, *C. J.* 37, 696). Formed also by desulphuration of di-tolyl-thio-urea in presence of NH_3 (Hofmann, *B.* 7, 1739). Needles (from ligroin). Nitric acid (S.G. 1.5) gives a di-nitro-derivative [197°], which forms crystalline $B'HNO_3$. Alcohol and HNO_3 (S.G. 1.4) produce di-nitro-*p*-tolyl-urea. Cyanogen passed into its ethereal solution forms $C_{18}H_{11}N_5O_2$, crystallising from ether in prisms, converted by dilute HCl aq into $NH.C \begin{smallmatrix} N(C_6H_4).CO \\ N(C_6H_4).CO \end{smallmatrix}$ [188.5°] (Landgrebe, *B.* 10, 1587). The cyanide is converted by boiling in alcoholic solution with aniline hydrochloride into $C_{22}H_{21}N_5$ aq [110°–115°].—Salt $B'_2H_2PtCl_6$.

Tri-*o*-tolyl-guanidine $C_{22}H_{23}N_5$, i.e. $C(NC_6H_4)(NHC_6H_4)_2$. [181°]. Formed by the action of *o*-toluidine in alcoholic solution in presence of lead oxide on di-*o*-tolyl-thiourea (Berger, *B.* 12, 1857; cf. Girard, *B.* 6, 445). Formed also when di-*o*-tolyl-thiourea is boiled for a long time (Barr, *B.* 19, 1769). Minute prisms. Yields a dicyanide $C_{24}H_{23}N_7$ [141°], converted by conc. HCl aq in alcoholic solution into $C_{24}H_{21}N_5O_2$ [179°].— $B'_2H_2PtCl_6$: yellow prisms.

Tri-*p*-tolyl-guanidine $C_{22}H_{23}N_5$. [123°]. S. (alcohol) 7.4 at 0°. Formed by heating di-*p*-tolyl-thio-urea with copper (Merz a. Weith, *Z.* 1868, 610), or, in alcoholic solution, with *p*-toluidine and PbO (Hofmann, *B.* 2, 459). Got by heating *p*-toluidine with PCl_5 and *p*-tolyl cyanate (Weith, *B.* 9, 820). Formed also when di-*p*-tolyl-urea is boiled for a long time (Barr, *B.* 19, 1768), and likewise by the action of *p*-toluidine on the product of the action of chlorine on tolyl cyanate (Nef, *A.* 270, 322). Needles (from ligroin). Yields a dicyanide $C_{24}H_{23}N_7$ [184°], which forms $B'HCl$ 3aq and $B'_2H_2PtCl_6$, and is converted by boiling with alcoholic HCl into di-tolyl-parabanic acid.

Salts.— $B'HCl$ aq. S. 6 at 0°.— $B'_2H_2PtCl_6$. S. 0.45 at 0°.— $B'HNO_3$. S. 0.7 at 0°.— $B'_2H_2SO_4$. Plates (from hot water). Neutral in reaction.

***p*-TOLYL HEPTADECYL KETONE**

[1.4] $C_{27}H_{54}Me.CO.C_6H_4$. [67°]. (278° at 15 mm.). Formed from toluene, stearyl chloride, and $AlCl_3$ (Krafft, *B.* 21, 2268). Oxidised by HNO_3 (S.G. 1.12) to *p*-toluic acid.

***p*-TOLYL-HEXYL-TOLUTRIAZINE DIHYDRIDE** $C_{21}H_{29}N_3$, i.e.

$C_6H_5Me \begin{smallmatrix} N.CH.C_6H_4 \\ N.N.C_6H_4Me \end{smallmatrix}$. [165°]. Formed by heating *o*-naphthol with toluene-*o*-azo-toluidine at 175° (Goldschmidt a. Pöltzer, *B.* 24, 1010). Needles, sol. hot benzene.— $BHCl$. [96°].— $B'_2H_2PtCl_6$. [171°]. Yellow crystalline pp.

***o*-TOLYL-HYDANTOIN** $C_{10}H_7N_3O_2$. [176°]. Formed by heating *o*-tolyl-amido-acetic acid with urea at 180° (Ehrlich, *B.* 16, 742). Light-yellow plates, sol. alcohol and hot water. On boiling with baryta-water it gives *o*-tolyl-hydantoic acid, which, when set free from its salts, at once splits up into water and *o*-tolyl-hydantoin.

***p*-Tolyl-hydantoin** $C_{10}H_7N_3O_2$, i.e. $CO \begin{smallmatrix} NH—CO \\ N(C_6H_4).OH \end{smallmatrix}$. [210°].

Formed, together with *p*-tolyl-hydantoic acid $CO(NH_2).N(C_6H_4).CH_2.CO_2H$, by fusing *p*-tolyl-amido-acetic acid with urea (Schwebel, *B.* 11, 1128). Needles (from water), v. sol. alcohol. *p*-Tolyl-hydantoic acid is crystalline, sl. sol. hot alcohol and hot water.

Di-*o*-tolyl-hydantoin $CO \begin{smallmatrix} N(C_6H_4).CO \\ N(C_6H_4).CH_2 \end{smallmatrix}$. [275°]. Got from *o*-tolyl-amido-acetic toluide and $COCl_2$ (Bischoff, *B.* 25, 2275).

Di-*p*-tolyl-hydantoin $CO \begin{smallmatrix} N(C_6H_4).CO \\ N(C_6H_4).CH_2 \end{smallmatrix}$. [175°]. Formed from *p*-tolyl-amido-acetic toluide and $COCl_2$ (Bischoff, *B.* 25, 2280). Plates (from alcohol), sl. sol. ligroin.

TOLYL-HYDRAZIDO-METHYL-THIAZOLE

DIHYDRIDE $CHMe.S \begin{smallmatrix} CH_2—N \\ CH_2—N \end{smallmatrix} > C.NH.NHC_6H_4$. Formed by heating tolyl-allyl-thio-semicarbazide with conc. HCl aq at 100° (Avenarius, *B.* 24, 270). The *p*-compound melts at 133°. Both the *o*- and the *p*-compounds form crystalline hydrochlorides.

***o*-TOLYL-HYDRAZIDO-PROPIONIC ACID** $C_6H_5Me.NH.NH.CHMe.CO_2H$. [143°]. Formed by the action of sodium-amalgam on the *o*-tolyl-hydrazide of pyruvic acid (Japp a. Klingemann, *C. J.* 53, 519). Small needles (from MeOH).

***o*-TOLYL-HYDRAZINE** $C_6H_5NH.NH$. [53°] (P.); [56°] (F.); [59°] (Gallinek a. Richter, *B.* 18, 8175). Prepared from *o*-toluidine in the same manner as phenyl-hydrazine is obtained from aniline (Fischer a. Böslér, *A.* 212, 838; Preund, *B.* 24, 4200). Glittering plates, slowly oxidised by air, forming a brown oil.— $B'HCl$ aq: needles.— $B'HNO_3$: plates. With $SOCl_2$ and ether it forms $C_6H_5NH.N:SO$, a yellow oil smelling like geraniums (Michaelis, *A.* 270, 119). Glucose yields *o*-tolyl-glucosazone $C_{20}H_{23}N_3O_4$ [201°] (Raschen, *A.* 239, 229). Di-methyl diketone forms $CH_3.C(N_2HC_6H_4).C(N_2HC_6H_4).CH_3$ [198°] (Japp a. Klingemann, *A.* 247, 224).

Formyl derivative $C_6H_5Me.NH.NHCHO$. [121°]. Formed from *o*-tolyl hydrazine and formamide. Needles (Gattermann, *B.* 25, 1078).

Acetyl derivative $C_6H_5NH.NHAc$. [104°]. Formed from *o*-tolyl-hydrazine and Ac_2O (G.).

Propionyl derivative $C_6H_5NH.NH.C_2H_5O$. [84°]. Formed from *o*-tolyl-hydrazine and propionic acid (G.). Colourless tables.

Benzoyl derivative $C_6H_5NH.NHBz$. [180°]. Got from the hydrazine and $BzCl$ in Et_2O (G.). Needles. Gives off all its nitrogen in the free state on boiling with Fehling's solution (Strache a. Iritzer, *M.* 14, 38).

***m*-Tolyl-hydrazine** $C_6H_5NH.NH$. [242°] (Buchka a. Schachtebek, *B.* 22, 841; cf. V. Meyer a. Lecco, *B.* 16, 2976). Oil.— $B'HCl$. Needles, v. sol. water and alcohol.

***p*-Tolyl-hydrazine** $C_6H_5NH.NH$. [61°]. [242°]. Obtained from *p*-toluidine (Fischer, *B.* 8, 539; 9, 890). White plates (from ether), sl. sol. water.

Reactions.—1. With $SOCl_2$ and ether it forms $C_6H_5NH.N:SO$ [112°], crystallising in yellow needles (Michaelis a. Ruhl, *A.* 270, 118).—2. $C_6H_5POCl_2$ forms $C_6H_5NH.N:PCl_2$ [162°], crystallising in prisms.—3. $POCl_3$ forms $(C_6H_5NH.NH).PO$ [189°].—4. **Acetone** forms $OMe_2(N_2HC_6H_4)$ [52°].—5. **Acetoacetic ether**

forms $C_{11}H_{11}N_2O_2$ [93°] (Knorr, B. 17, 550).—6. *Oxalic ether* forms $NHC_2H_4NH.CO.CO.Et$ [133°] (Preund, B. 24, 4198).—7. *Di-methyl diketone* yields $CH_3.C(NHC_2H_4).C(NHC_2H_4).CH_3$ [230°], and $CH_3.C(NHC_2H_4).Ac$ [161°] (Japp, C. J. 53, 544).

Salt.— $B'C_6H_4PH_2O_2$. [148°] (Michaelis, A. 270, 134).

Toluene-p-phosphinate $B'C_6H_4PH_2O_2$. [161°].

Formyl derivative

$C_6H_4Me.NH.NH.CHO$. [164°]. Formed by heating the alcoholic solution of *p*-tolyl-hydrazine with chloroform and potash. Formed also by heating *p*-tolyl-hydrazine with formamide at 180° (Ruhemann, C. J. 55, 248). Plates (from water), v. sol. alcohol.

Acetyl derivative $C_6H_4Me.NH.NH.Ac$. [121°]. Formed from *p*-tolyl-hydrazine and $AcOH$ (Gattermann, B. 25, 1080). Plates.

Propionyl derivative [170°]. Needles.

Dibenzoyl derivative [188°] (Fischer).

Di-o-tolyl-hydrazine.

Formyl derivative $(C_6H_4)_2N.NH.CHO$. [139°]. Formed from $C_6H_4NH.NH.CHO$ and $CuSO_4$ (Gattermann, B. 25, 1078). Plates.

Acetyl derivative $(C_6H_4)_2N.NH.Ac$. [191°]. Formed in like manner from acetyl-o-tolyl-hydrazine and $CuSO_4$. Needles.

Propionyl derivative [167°]. Needles.

Benzoyl derivative [209°]. Needles.

u-Di-p-tolyl-hydrazine $(C_6H_4)_2N.NH_2$. [172°]. Formed by reduction of di-tolyl-nitrosamine with zinc-dust and $HOAc$ (Lehne, B. 13, 1546). Plates, v. sol. alcohol and benzene.— $B'HCl$.

Formyl derivative $(C_6H_4)_2N.NH.CHO$. [146°]. Formed from formyl-*p*-tolyl-hydrazine and $CuSO_4$ (Gattermann, B. 25, 1079). Plates.

Acetyl derivative. [176°]. Needles.

Propionyl derivative [171.5°]. Needles.

Benzoyl derivative. [187°]. Needles.

s-Di-o-tolyl-hydrazine $C_6H_4NH.NHC_6H_3$. *o-Hydrazo-toluene*. [165°] (P.); [146°] (S.). Formed by reduction of *o*-toluene-azo-toluene by sodium-amalgam (Petrieff, B. 6, 557; Schultz, B. 17, 467). Converted into di-amido-ditolyl [3:4:1] $C_6H_4Me(NH_2).C_6H_4Me(NH_2)$ [1:3:4] [128°] by heating with HCl . The di-amido-derivative $C_6H_4(NH_2).NH.NH.C_6H_4(NH_2)$ [180°] is a product of the action of sodium-amalgam on nitro-*p*-toluidine (Buckney, B. 11, 1453).

s-Di-m-tolyl-hydrazine $C_6H_4NH.NHC_6H_3$. Formed by reducing *m*-toluene-*m*-azo-toluene by alcoholic ammonium sulphide (Goldschmidt, B. 11, 1626; Barsilowsky, A. 207, 118). Liquid, converted by H_2SO_4 into a di-amido-ditolyl.

s-Di-p-tolyl-hydrazine $C_6H_4NH.NHC_6H_3$. [126°]. Formed in like manner from *p*-toluene-*p*-azo-toluene (Melms, B. 8, 553) and by the action of zinc-dust and $NaOHAq$ on *p*-nitro-toluene (Janovsky, M. 9, 829). Tables or needles, v. e. sol. alcohol. In alcoholic solution it is readily oxidised by air to $C_6H_4.N_2.C_6H_3$. Dilute H_2SO_4 converts it into toluidine and toluene-azo-toluene. On treatment in alcoholic solution with hydrochloric acid it changes to tolylene-tolyl-diamine. The di-amido-derivative [1:2:4] $C_6H_4Me(NH_2).NH.NH.C_6H_4Me(NH_2)$ [4:1:2] obtained from $C_6H_4Me(NH_2).N_2.C_6H_4Me(NH_2)$ by reducing with sodium-amalgam, is crystalline

and yields $B''H_2SO_4$, $B''2HCl$, $B''2HBr$, and $B''H_2PtCl_6$ (Graeff, A. 229, 352).

Reference.—OXY-TOLYL-HYDRAZINE.

o-TOLYL-HYDRAZINE SULPHONIC ACID

$C_6H_4Me(NH_2).SO_3H$ [1:2:4]. Formed by adding *o*-diazotoluene *p*-sulphonic acid to a cold solution of $SnCl_2$ (Limpricht, B. 18, 2193). Colourless needles, v. sol. hot water, nearly insol. alcohol.— KA' 2aq: orange-red prisms.— BaA' 2aq: yellow crystalline powder.

o-Tolyl-hydrazine sulphonic acid

$C_6H_4Me(NH_2).SO_3H$ [1:2:2]. Formed by heating *o*-tolyl-hydrazine (1 pt.) with conc. H_2SO_4 (5 pts.) at 100° (Gallinek a. Richter, B. 18, 8175). Thin needles (containing 3aq). By boiling with aqueous $CuSO_4$ it is quantitatively decomposed into a toluene sulphonic acid and nitrogen.— NaA' 3½aq.— BaA' 4aq.— ZnA' 3½aq.— PbA' 6aq.— $PbA'_2(OH)_4$. Sparingly soluble needles.

p-Tolyl-hydrazine-o-sulphonic acid

$C_6H_4Me(NH_2).SO_3H$ [1:4:2]. [274°]. Formed by reducing *p*-diazotoluene *o*-sulphonic acid with Na_2SO_3 (Brackett a. Hayes, Am. 9, 401) or HCl and $SnCl_2$ (Pasche, B. 21, 3416). Tables, sl. sol. cold water. Decomposed by fusion. Not attacked by warm H_2SO_4 .

p-Tolyl-hydrazine m-sulphonic acid

$C_6H_4Me(NH_2).SO_3H$ [1:3:4]. Obtained by reducing *p*-diazotoluene *m*-sulphonic acid by cooled $SnCl_2$ (Limpricht, B. 18, 2193). Slender prisms, sol. hot water. $FeCl_3$ evolves nitrogen in the cold. Conc. H_2SO_4 at 80° forms a red amorphous substance (Schneider, Am. 8, 271).

p-Tolyl-hydrazine disulphonic acid

$C_6H_4Me(NH_2)(SO_3H)_2$. Formed by adding *p*-diazotoluene disulphonic acid to a cold solution of $SnCl_2$ (Limpricht, B. 18, 2193). Nodules, v. sol. water.— BaH_2A' 2½aq: tables.

Di-tolyl-hydrazine disulphonic acid

$C_6H_4Me(SO_3H).NH.NH.C_6H_4Me(SO_3H)$. A product of the reduction of the corresponding azo-compound by $SnCl_2$ (Neale, A. 203, 72). Crystalline powder (containing 2½aq), sl. sol. water.— BaA' 5aq.— CaA' 3½aq: monoclinic efflorescent prisms.

Reference.—NITRO-TOLYL-HYDRAZINE SULPHONIC ACID.

o-TOLYL-IMIDO-DIACETIC ACID

[1:2] $C_6H_4Me.N(CH_2.CO_2H)_2$. [c. 160°]. Formed by heating *o*-tolyl-amido-acetic acid (1 mol.) with chloro-acetic acid (1 mol.), Na_2CO_3 (1½ mols.) and a little water at 140° (Bischoff, B. 23, 1994; 25, 2270). White crystals, insol. ligroin, sl. sol. ether, m. sol. alcohol.— NH_4A' . [160°]. V. sol. Aq.

Amide $C_6H_4N(CH_2.CO.NH_2)_2$. [164°]. Plates.

Di-o-toluide $C_6H_4N(CH_2.CO.NHC_6H_3)_2$. [150°].

Imide $C_6H_4N<\frac{CH_2.CO}{CH_2.CO}>NH$. [146°].

Prisms (from alcohol), sl. sol. water.

o-Tolylamic acid

$C_6H_4N(CH_2.CO_2H).CH_2.CO.NHC_6H_3$. [148°]. Crystals (from alcohol).

p-Tolylimido-diacetic acid

[1:4] $C_6H_4Me.N(CH_2.CO_2H)_2$. *Dihydrocotylamic acid*. [c. 140°]. Formed by the action of $CH_3Cl.CO_2H$ on *p*-tolyl-glycocoll (Meyer, B. 14, 1323; Bischoff, B. 23, 2000). Needles (from water). Very unstable.— CuA' 2aq: green needles.— Ag_2A' (NO_3): needles.—*p*-Toluidine

salt $(C_6H_5NH_2)HA'$. [119°]. Crystals, sol. hot water.

Mono-amide. [222°]. A product of the action of Ac_2O on the compound [168°] got from chloro-acetic acid and *p*-toluidine (Bischoff, *B.* 25, 2280).

Di-amide $C_6H_5N(CH_2CO.NH_2)_2$. [250°].

Di-*p*-toluide $C_6H_5N(CH_2CO.NHC_6H_4)_2$. [251°]. Long needles (from alcohol).

Amide *p*-toluide

$C_6H_5N(CH_2CO.NH_2)CH_2CO.NHC_6H_4$. [210°].

***p*-Tolylamic acid**

$C_6H_5N(CH_2CO_2H)CH_2CONHC_6H_4$. [222°].

Needles, insol. water, sol. hot alcohol.

***p*-TOLYL-IMIDO-DIACRYLIC ETHER**

$C_6H_5MeN(CH:CH.CO_2Et)_2$. [73°]. Formed from *p*-toluidine and formyl-acetic ether (Von Pechmann, *B.* 25, 1053). Yellow needles (from dilute alcohol).

***o*-TOLYL- β -IMIDO-BENZYL-MALONIC**

ETHER $C_6H_5NO_2$, *i.e.*

$C_6H_5C(NC_6H_5)CH(CO_2Et)_2$. [95°]. Formed by the action of α -chloro-benzylidene-*o*-toluidine upon sodium-malonic ether (Just, *B.* 19, 985). Crystals, v. sol. ether. Split up by dilute $HClAq$ at 120° into acetophenone and *o*-toluidine. The *p*-isomeride is liquid.

***o*-TOLYL- β -IMIDO-BUTYRIC ACID**

$C_6H_5MeN:OMe.CH_2CO_2H$. [112°]. Formed by heating acetoacetic ether with *o*-toluidine at 150° (Knorr, *B.* 17, 542; Pawlewski, *B.* 22, 2203). Needles (from hot water), converted by conc. H_2SO_4 into (*Py.* 1)-oxy-(*B.* 4, *Py.* 3)-dimethyl-quinoline.

***p*-Tolyl- β -imido-butyric acid.** Formed in like manner from *p*-toluidine. Crystals. Converted by H_2SO_4 into (*Py.* 1)-oxy-(*B.* 2, *Py.* 3)-di-methyl-quinoline.

***p*-TOLYL IODO-ETHYL SULPHONE**

$C_6H_5SO_2CH_2CH_2I$. [100°]. Formed from tolyl oxy-ethyl sulphone and $HIAq$ at 160° (Otto, *J. pr.* [2] 30, 357). Crystals, v. sol. hot alcohol.

TOLYL IODO-METHYL SULPHONE

$C_6H_5SO_2CH_2I$. [126°]. Formed by heating sodium toluene sulphinate with CH_3I and alcohol (Otto, *B.* 21, 655). Small needles, v. e. sol. hot alcohol.

DI-*p*-TOLYL KETONE $CO(C_6H_5Me)_2$. [92°].

(333°) at 725 mm. Formed by oxidation of di-tolyl-methane (Weiler, *B.* 7, 1183), of *u*-di-tolyl-ethane (O. Fischer, *B.* 7, 1195), and of *u*-di-tolyl-ethylene (Hepp, *B.* 7, 1414) by chromic acid mixture.

Preparation.—50 g. $AlCl_3$, 65 c.c. toluene, 50 c.c. CS_2 , and 11 c.c. of a solution of $COCl_2$ in CS_2 , saturated at 0° are put into a corked half-litre flask and gently warmed. After 20 minutes HCl is allowed to escape and a second 11 c.c. of CS_2 , saturated with phosgene is added. The operation is repeated 2 or 3 times; the yield is 50 p.c. of the calculated (Elbs, *J. pr.* [2] 35, 467; cf. Ador a. Crafts, *B.* 10, 2174).

Properties.—Crystals (from alcohol). Converted by HNO_3 at 250° into benzoyl-terephthalic acid. Reduced by HI and P to di-tolyl-methane (Ador a. Rilliet, *B.* 12, 2303).

Oxim $(C_6H_5)_2C:NOH$. [163°]. Prisms (Goldschmidt, *B.* 23, 2746). Decomposes on keeping with sudden evolution of nitrous fumes. Conc.

H_2SO_4 at 100° forms the *p*-toluide of *p*-toluic acid.

Di-*p*-tolyl diketone $C_6H_5CO.CO.C_6H_5$, *p*-Toli. [105°]. Formed by boiling toluoin (1 pt.) with HNO_3 (2 pts.) (Stierlin, *B.* 22, 381). Yellow plates (from warm alcohol). Gives a violet colour when boiled with alcoholic potash.

(a)-*Oxim* $C_6H_5C(NO_2)C(NO_2)C_6H_5$. [217°]. Plates or needles, sl. sol. alcohol. Yields a diacetyl derivative [134°].

(β)-*Oxim* [225°]. Formed, together with the (α)-*oxim*, by the action of hydroxylamine hydrochloride on the ketone. Needles, v. sol. alcohol. Yields a di-acetyl derivative [144°].

Di-*p*-tolyl tetraketone

$C_6H_5CO.C(OH)_2CO.CO.C_6H_5$. [88°]. Formed by the action of nitric acid (S.G. 13) on $C_6H_5CO.CH(OH)CO.CO.C_6H_5$ (Söderbaum, *B.* 25, 3474). Prisms (containing $(C_6H_5O_2)_2CS_2$) (when crystallised from CS_2).

Di-*oxim*

$C_6H_5C(NO_2)CO.CO.C(NO_2)C_6H_5$. [181°]. Plates (containing $EtOH$) (from alcohol).

Di-*oxim*

$C_6H_5CO.C(NO_2)C(NO_2)CO.C_6H_5$. So called ' β)-nitro-cymene.' [125°]. Mol. w. 324 (by Raoult's method). Formed by the action of nitric acid on cymene and on *p*-tolyl methyl ketone (Holleman, *R. T. C.* 6, 60; cf. Landolph, *B.* 6, 937; Fittica, *A.* 172, 314). Needles, v. sol. warm alcohol. Converted by $NaOHAq$ into *p*-toluic acid. Zinc-dust and $HOAc$ reduce it to $C_6H_5CO.CH_2CH_2CO.C_6H_5$. [159°]. Alcoholic NH_3 forms *p*-toluic amide and $C_6H_5N_3O_2$. [162°]. Boiling Ac_2O forms $C_6H_5N_3O_4Ac_2O$. [167°].

Reference.—**OXY-DI-TOLYL KETONE.**

TOLYL-MALONAMIC ACID v. MALONIC ACID.

TOLYL-MELAMINE v. *Cyanuramide* in the article on CYANIC ACIDS.

***o*-TOLYL-MERCAPTAN** [1:2] $C_6H_5Me.SH$.

[15°]. (188°) (H.); (193°) (V.). Formed by reducing (4,1,2)-bromo-tolyl mercaptan (Hübner, *A.* 169, 30; Vallin, *B.* 19, 2953). Prepared by boiling *o*-tolyl ethyl dithiocarbonate with alcoholic potash, the yield being 70 p.c. of the theoretical amount (Leuckart, *J. pr.* [2] 41, 189). Plates.— $Pb(SC_6H_5)_2$. Brick-red pp., turning white in air.

***m*-Tolyl mercaptan** [1:3] $C_6H_5Me.SH$. [c. 200°]. Formed by reducing toluene *m*-sulphonic chloride with tin and HCl (Hübner, *A.* 169, 51) and by boiling *m*-tolyl ethyl xanthate with alcoholic potash (L.). Colourless liquid with intense odour of mercaptan. Volatile with steam. In ammoniacal alcoholic solution it is oxidised by air to *m*-tolyl disulphide.

***p*-Tolyl mercaptan** [1:4] $C_6H_5Me.SH$. [43°]. (188°) (J.); (191°) (Crafts, *B.* 19, 3180; Otto, *B.* 19, 3129); (194°) (Vallin, *B.* 19, 2953). Formed by reducing toluene *p*-sulphonic chloride with tin and HCl (Märcker, *A.* 186, 79; Javorsky, *Z.* 1865, 222). Formed also by heating *p*-tolyl ethyl xanthate with alcoholic potash (L.). Formed also from di-*p*-tolyl disulphide, alcohol, and H_2S (Otto a. Rössing, *B.* 19, 3180). Unctuous laminae (from ether), volatile with steam. Conc. H_2SO_4 forms a blue solution. Readily oxidised to di-*p*-tolyl disulphide [46°]. Chloro-acetone forms $C_6H_5S.CH_2.CO.CH_3$ (151° at 15 mm.); S.G. 1.0986 which yields a phenyl-hydrazide

[62°] (Dellale, *A.* 260, 268).— $\text{Hg}(\text{SC}_6\text{H}_4)_2$.— $\text{C}_6\text{H}_5\text{S.HgCl}$. Plates.

Ethyl ether $\text{C}_6\text{H}_5\text{SEt}$. (221°). S.G. 1.10016. Colourless oil (Otto, *B.* 13, 1277).

References.—AMIDO- and BROMO- TOLYL MERCAPTAN.

***o*-TOLYL-MESITYL-THIO-UREA**

$\text{C}_6\text{H}_4\text{.NH.CS.NHC}_6\text{H}_3\text{Me}_3$. [167°]. Formed from *o*-toluidine and mesityl thiocarbimide (Eisenberg, *B.* 15, 1014). Needles, insol. Aq.

DI-TOLYL-METHANE $\text{CH}_2(\text{C}_6\text{H}_4)_2$. [23°]. (286°).

Formation.—1. From formic aldehyde (or methylal), toluene, and H_2SO_4 (Weiler, *B.* 7, 1181).—2. By reducing di-tolyl ketone with HI and P (Ador a. Rilliet, *B.* 12, 2302).—3. A product of the action of AlCl_3 and toluene on CH_2Cl_2 , on CH_3Cl , or on CCl_3NO_2 (Friedel a. Crafts, *A. Ch.* [6] 11, 266; *Bl.* [2] 43, 50; Elbs a. Wittich, *B.* 18, 347).

Properties.—Prisms, v. sol. ether. Oxidised by chromic acid mixture to di-tolyl ketone, toluyl-benzoic acid, and $\text{CO}(\text{C}_6\text{H}_4\text{CO}_2\text{H})_2$. Yields a di-nitro-derivative [164°].

Tri-tolyl-methane $\text{CH}(\text{C}_6\text{H}_4)_3$. [73°]. (377°). Obtained from tri-amido-tri-tolyl-carbinol (Rosenstiehl a. Gerber, *A. Ch.* [6] 2, 353). Crystalline.

References.—DI-BROMO- and DI-CHLORO-, DI-TOLYL-METHANE.

***o*-TOLYL-METHYL-*p*-AMIDO-PHENOL**

Methyl derivative $\text{C}_6\text{H}_4\text{NMe.C}_6\text{H}_4\text{OMe}$. (336° cor.). From $\text{C}_6\text{H}_4\text{NH.C}_6\text{H}_4\text{OH.KOH}$, and MeI (Philip, *J. pr.* [2] 34, 59). Oil.

TOLYL-METHYL-AMINE v. METHYL-TOLUIDINE, METHYL-BENZYL-AMINE, and AMIDO-XYLENE.

Di-*p*-tolyl-methyl-amine $(\text{C}_6\text{H}_4)_2\text{NMe}$. (235°–240° at 20 mm.). Formed from ditolylamine, MeOH, and HCl at 250°–280° (Girard, *Bl.* [2] 24, 120). Does not combine with acids.

DI-TOLYL-DI-METHYL-DI-TRIAZYL

$\text{N}_2\text{N}(\text{C}_6\text{H}_4)_2\text{C} \begin{smallmatrix} \text{N}(\text{C}_6\text{H}_4)_2\text{N} \\ \text{C} \end{smallmatrix} \text{C} \begin{smallmatrix} \text{N}(\text{C}_6\text{H}_4)_2\text{N} \\ \text{C} \end{smallmatrix} \text{OMe}$. (259°–260°). Formed by boiling *p*-tolyl-hydrazine cyanide $(\text{C}_6\text{H}_4\text{NH.NH}_2)_2\text{Cy}_2$ with Ac_2O (Bladin, *B.* 22, 3114). Crystals (from alcohol), m. sol. alcohol.

***p*-TOLYL-METHYL-BENZYL KETONE**

$\text{C}_6\text{H}_4\text{Me.COCH}_2\text{C}_6\text{H}_4\text{Me}$. [102°]. Got by reducing *p*-toluoln with zinc and alcoholic HCl (Stierlin, *B.* 22, 383). Needles, insol. water, v. sol. benzene.

***o*-TOLYL-METHYLENE-AMINE**

$\text{C}_6\text{H}_4\text{N:CH}_2$ (?). Formed by adding *o*-toluidine to a solution of formic aldehyde (Wellington a. Tollens, *B.* 18, 3307). Colourless syrup.

***p*-Tolyl-methylene-amine** $\text{C}_6\text{H}_4\text{N:CH}_2$ (?). [c. 122°]. Formed, together with a polymeride sl. sol. benzene and alcohol, by adding *p*-toluidine to a solution of formic aldehyde (W. a. T.). Crystals, v. sol. benzene.

Di-*o*-tolyl-methylene-diamine $(\text{C}_6\text{H}_4\text{NH})_2\text{CH}_2$. (over 350°). Formed, together with the following solid isomeride, by heating *o*-toluidine with CH_2Cl_2 at 110°–115° (Grünhagen, *A.* 256, 305). Liquid, v. sol. ether and alcohol.— $\text{B}''\text{H}_2\text{PtCl}_6$: brown amorphous powder.

Isomeride [c. 135°]. Crystalline powder, sl. sol. cold alcohol.—Salts: $\text{B}''2\text{HCl}$.— $\text{B}''2\text{HBr}$.— $\text{B}''\text{H}_2\text{SO}_4$.— $\text{B}''2\text{H}_2\text{PO}_4$.— $\text{B}''3\text{H}_2\text{C}_2\text{O}_4$.— $\text{B}''2\text{H}_2\text{C}_2\text{O}_4$. Radiating aggregates.

Di-*p*-tolyl-methylene-diamine

$(\text{C}_6\text{H}_4\text{NH})_2\text{CH}_2$. (above 350°). Formed, together with the solid isomeride, by heating *p*-toluidine with CH_2Cl_2 (G.). Oil, v. sol. ether.— $\text{B}''\text{HCl}$.— $\text{B}''\text{H}_2\text{PtCl}_6$.— $\text{B}''\text{HAuCl}_4$.

Isomeride $\text{C}_6\text{H}_4\text{N}_2$ [c. 156°]. (over 350°). Amorphous, sl. sol. ether.— $\text{B}''2\text{HCl}$ (?).— $\text{B}''\text{H}_2\text{PtCl}_6$.— $\text{B}''2\text{HAuCl}_4$.— $\text{B}''2\text{H}_2\text{C}_2\text{O}_4$. Crystalline crusts.

Di-*p*-tolyl-di-methylene-diamine

$\text{C}_6\text{H}_4\text{N} \begin{smallmatrix} \text{CH}_2 \\ \text{CH}_2 \end{smallmatrix} \text{NC}_6\text{H}_4$. [90°]. A product of the action of CH_2Cl_2 on *p*-toluidine at 100° (Grünhagen, *A.* 256, 296). Granules, sol. hot alcohol. Converted by nitrous acid into a crystalline nitroso-derivative $(\text{C}_6\text{H}_4\text{N})_2\text{C}_2\text{H}_4(\text{NOH})$ (?)— $\text{B}''2\text{HCl}$.— $\text{B}''2\text{HAuCl}_4$.— $\text{B}''2\text{HBr}$.— $\text{B}''\text{H}_2\text{SO}_4$.

***o*-Tolyl-trimethylene-diamine**

$\text{C}_6\text{H}_4(\text{NH}_2)_3\text{NHC}_6\text{H}_7$. (281°). Formed by reducing *o*-tolyl-pyrazole dihydride in alcoholic solution by sodium (Balbiano, *G.* 18, 354). Oil.

***p*-Tolyl-trimethylene-diamine**

$\text{C}_6\text{H}_4(\text{NH}_2)_3\text{NHC}_6\text{H}_7$. [c. –15°]. (287°). A product of the action of Na on an alcoholic solution of *p*-tolyl-pyrazole (Balbiano). Liquid. Oxalate. [208°]. Spherical groups of minute needles.

***p*-TOLYL METHYLENE METHYL SULPHONE KETONE** $\text{C}_6\text{H}_4\text{SO}_2\text{CH}_2\text{CO.CH}_3$. [51°]. Formed from chloro-acetone and sodium toluene *p*-sulphinate (Otto, *J. pr.* [2] 36, 401). Silky needles. Yields a bromo-derivative [130°].

***m*-TOLYL-METHYLENE-PHTHALIDE**

$\text{C}_6\text{H}_4 \begin{smallmatrix} \text{C}(\text{CH}_2\text{C}_6\text{H}_4) \\ \text{CO} \end{smallmatrix} \text{O}$. [153°]. Formed by heating *m*-tolyl-acetic acid with phthalic anhydride and a little NaOAc (Heilmann, *B.* 23, 3157). Needles (from ligroin), sl. sol. ether.

***p*-Tolyl-methylene-phthalide** $\text{C}_6\text{H}_4\text{CH}_2\text{O}$

p-Xylal-phthalide. [151°]. Formed in like manner from *p*-tolyl-acetic acid (Ruhemann, *B.* 24, 3965). Yellow needles (from alcohol), sl. sol. ether. Nitrous acid passed into its solution in chloroform forms $\text{C}_6\text{H}_4 \begin{smallmatrix} \text{C}(\text{C}(\text{NO}_2)\text{C}_6\text{H}_4) \\ \text{CO} \end{smallmatrix} \text{O}$ [140°], which may be reduced to the compound $\text{C}_6\text{H}_4 \begin{smallmatrix} \text{CH}_2\text{C}_6\text{H}_4 \\ \text{CO.O} \end{smallmatrix}$. [116°].

Reference.—NITRO-TOLYL-METHYLENE-PHTHALIDE.

***m*-TOLYL-METHYLENE-PHTHALIMIDINE**

$\text{C}_6\text{H}_4 \begin{smallmatrix} \text{C}(\text{CH}_2\text{C}_6\text{H}_4) \\ \text{CO} \end{smallmatrix} \text{NH}$. [165°]. Formed by heating *m*-tolyl-methylene-phthalide with alcoholic ammonia (Heilmann, *B.* 23, 3161). Yellowish needles.

***p*-Tolyl-methylene-phthalimidine** $\text{C}_6\text{H}_4\text{NH}$. [204°]. Formed by heating *p*-tolyl-methylene-phthalide with alcoholic NH_3 , the compound $\text{NH}_2\text{CO.C}_6\text{H}_4\text{CO.CH}_2\text{C}_6\text{H}_4$ being first formed (Ruhemann, *B.* 24, 3968). Converted by passing nitrous acid through its solution in chloroform into $\text{C}_6\text{H}_4 \begin{smallmatrix} \text{C}(\text{C}(\text{NO}_2)\text{C}_6\text{H}_4) \\ \text{CO} \end{smallmatrix} \text{NH}$ [227°].

Isomeride $\text{C}_6\text{H}_4 \begin{smallmatrix} \text{CH:C}_6\text{H}_4 \\ \text{CO.NH} \end{smallmatrix}$. [228°]. Formed by heating $\text{C}_6\text{H}_4 \begin{smallmatrix} \text{CH:C}_6\text{H}_4 \\ \text{CO.O} \end{smallmatrix}$ with alcoholic ammonia (R.).

Reference.—NITRO-TOLYL-METHYLENE-PHTHALIMIDINE.

DI-*p*-TOLYL TRIMETHYLENE DISULPHONE $C_6H_4(SO_2C_6H_4)_2$. [125°]. Formed from trimethylene bromide and sodium toluene *p*-sulphinate (Otto, *B.* 24, 1834). Plates. Converted by alcoholic potash at 120° into the compound $O(CH_2CH_2CH_2SO_2C_6H_4)_2$. [80°].

TOLYL-METHYL-IMESATIN *v. Toluide* of *Methyl-isatin*.

***m*-TOLYL METHYL KETONE** $C_6H_4CO.CH_3$. *Methyl-acetophenone*. (219°). Formed by distilling calcium *m*-toluate with calcium formate (Buchka a. Irish, *B.* 20, 1766).

Tolyl methyl ketone. (225°). S.G. 22.9891. V.D. 4.58. Formed, together with the *p*-compound, by the action of $AlCl_3$ on toluene and $AlCl_3$ (Essner a. Gossin, *Bl.* [2] 42, 95). This is perhaps the *o*-compound.

***p*-Tolyl methyl ketone**. (217°) (M.); (230° cor.) (W.). Formed by the action of $AlCl_3$ on a mixture of toluene and Ac_2O or $AlCl_3$ (Michaelis, *B.* 15, 185; Claus, *B.* 19, 234). Formed also by heating toluene with $HOAc$, $ZnCl_2$, and $POCl_3$ (Frey, *J. pr.* [2] 43, 114) and as a by-product in the oxidation of (*u*)-nitro-cymene (Widman, *B.* 19, 587). Oil. Yields a dibromide $C_6H_4Br_2O$ [100°]. $KMnO_4$ forms terephthalic acid. Alkaline K_2FeCy_4 forms *p*-toluic and *p*-tolyl-glyoxylic acids (B. a. K.). HNO_3 forms $C_6H_4N_2O_4$ [125°], which is reduced by zinc-dust and $HOAc$ to $C_6H_4(CO.C_6H_4)_2$ (Holleman, *R. T. C.* 10, 211).

Oxim [88°]. Crystals (from ligroin).

Phenyl-hydrazide [97°]. Prisms.

Reference.—AMIDO-, IODO-, and OXY-, TOLYL METHYL KETONE.

***o*-TOLYL METHYL KETONE TETRAHYDRIDE** $CH_2<\begin{smallmatrix} CH_2.CMe \\ CH_2.CMe \end{smallmatrix}>C.CO.CH_3$. (206°).

Formed from *ω*-di-acetyl-pentane by treatment with conc. H_2SO_4 (Kipping a. Perkin, jun., *C. J.* 57, 18). Oil, smelling like peppermint. Does not combine with $NaHSO_4$. In moist ether it is reduced by Na to the hexahydride.

Oxim C_6H_4NO . Liquid.

Phenyl hydrazide $C_{15}H_{20}N_2$. Oil.

Tolyl methyl ketone hexahydride *v. METHYL-HEXAMETHYLENOL METHYL KETONE*.

***m*-TOLYL-METHYL-MALONIC ACID**

[1.3] $C_6H_4Me.CO_2CH(CO_2H)_2$. [133°]. Formed by saponification of the ether (Poppe, *B.* 23, 110). Rhombohedra, sl. sol. water.— K_2A'' : needles.

Methyl ether Me_2A' . (c. 300°).

Ethyl ether Et_2A'' . (320°). Formed from *ω*-bromo-*m*-xylene and sodium malonic ether. Oil. Converted by alcoholic NH_3 at 150° into $C_6H_4Me.CO_2CH(CO_2Et).CO.NH_2$ [186°], which on warming with water forms the ammonium salt $C_6H_4Me.CO_2CH(CO_2Et).CO_2NH_2$ [77°]. Et_2A'' is converted by methylamine into the methylamide $C_6H_4Me.CO_2CH(CO_2Et).CONHMe$ [120°], and by aniline into $C_6H_4Me.CO_2CH(CO_2NHPh)_2$ [188°].

Di-*m*-tolyl-di-methyl-malonic ether

$(C_6H_4Me.CO_2)_2C(CO_2Et)_2$. [122°]. A product of the action of *ω*-bromo-*m*-xylene on sodium malonic ether (Poppe, *B.* 23, 109).

***o*-TOLYL-METHYL-OXAZOLINE** $C_{11}H_9NO$ *i.e.* $CHMe.S>C.O.C_6H_4$. (258°). Formed by boiling $C_6H_4.CO.NH.CH_2.CHMeBr$ with alcoholic potash (Salomon, *B.* 26, 1823). Oil.— $B'C_6H_4N_2O$. [129°].— $B'H_2PtCl_6$.

VOL. IV.

***p*-Tolyl-methyl-oxazoline** $C_{11}H_9NO$. (265°). Formed from the bromopropyl-amide of *p*-toluic acid (Salomon, *B.* 26, 1826). Oil.—Picrate $B'C_6H_4N_2O$. [183°].— $B'H_2PtCl_6$. [184°].

***p*-TOLYL-DI-METHYL-PHOSPHINE** $C_6H_4PMe_2$. (210°). Formed from $C_6H_4POCl_2$ and $ZnMe_2$ (Czimis, *B.* 15, 2014). Oil, oxidised by HgO to $C_6H_4PMe_2O$. CS_2 forms $C_6H_4PMe_2CS_2$ [110°] crystallising in red plates.

Methylo-iodide $B'MeI$. [255°]. Needles. Yields $B'MeI$, and $B'Me_2PtCl_6$.

Benzylchloride. Yields $B'_2(C_6H_4)_2PtCl_6$ [226°], a yellow crystalline pp.

***p*-TOLYL-METHYL-PHTHALIMIDE** [4.2.1] $C_6H_4Me.CO.O.N.C_6H_4Me$. [180°]. Formed by distilling (4.2.1)-methyl-phthalic acid with *p*-toluidine (Niementskowski, *M.* 12, 630). Crystalline mass, *v. e.* sol. chloroform, insol. water.

***p*-TOLYL-METHYL-PHTHALIMIDINE** $C_6H_4<\begin{smallmatrix} CO \\ CH \end{smallmatrix}(CH_2.C_6H_4Me)>NH$. [149°]. Formed from *p*-tolyl-methylene-phthalimidine, HI and P (Ruhemann, *B.* 24, 3969). Needles.

DI-*p*-TOLYL-METHYL-PIPERAZINE $C_{18}H_{24}N_2$. [105°]. Formed from di-*p*-tolyl-propylene-diamine, ethylene bromide, and Na_2CO_3 . Needles (from alcohol) (Bischoff, *B.* 25, 3278).

***o*-TOLYL-METHYL-PROPYLENE-ψ-THIO-UREA** $CHMe.S>C.NMe.C_6H_4$. (c. 295°). Formed

from *o*-tolyl-propylene-ψ-thio-urea and MeI (Prager, *B.* 22, 2999). Yields (S)-methyl-taurine on oxidation.— $B'C_6H_4N_2O$. [138°].— $B'HI$. [166°].— $B'_2H_2PtCl_6$. Decomposes over 200°.

***p*-TOLYL-DI-METHYL-PYRROLE** $(C_6H_4)N<\begin{smallmatrix} CMe:CH \\ CMe:CH \end{smallmatrix}>$. (255°). Got by heating the di-carboxylic acid (Knorr, *B.* 18, 308). Crystals, volatile with steam.

Reference.—AMIDO-TOLYL-DI-METHYL-PYRROLE.

***p*-TOLYL-DI-METHYL-PYRROLE DICARB- OXYLIC ACID** $(C_6H_4)N<\begin{smallmatrix} CMe:C.CO_2H \\ CMe:C.CO_2H \end{smallmatrix}>$. Got by

saponifying its ether, which is formed by mixing acetic acid solutions of di-acetyl-succinic ether and *p*-toluidine (Knorr, *B.* 18, 304). Needles, decomposes at about 250°, with evolution of CO_2 .— K_2A'' .— $AgHA''$.

Ethyl ether Et_2A' . [67°]. Tables.

Reference.—AMIDO-TOLYL-DI-METHYL-PYRROLE DICARBOXYLIC ACID.

***p*-TOLYL-DI-METHYL-SULPHAMIDE** $SO_2(NMe_2).NH.C_6H_4$. [91°]. Formed from $NMe_2.SO_2Cl$ and *p*-toluidine (Behrend, *A.* 222, 129). Crystals, *v. sol.* alcohol and ether.

***p*-TOLYL METHYL SULPHONE** $C_6H_4.SO_2CH_3$. [87°]. Formed by the action of conc. KOH on *p*-tolyl-sulphono-acetic acid (Otto, *B.* 18, 161). Got also from $C_6H_4.SO_2Na$ and MeI (Otto). Needles (from very dilute alcohol), *v. sol.* hot water.

***o*-TOLYL-METHYL-THIAZOLINE**

$CHMe.S>C.C_6H_4$. (284°–295°). Formed by heating *o*-toluic bromo-propylamide with P_2S_5 at 150° (Salomon, *B.* 26, 1828). Oil.— $B'C_6H_4N_2O$. [186°].

***p*-Tolyl-methyl-thiazoline** $C_{11}H_9NS$. (295°). Oil.— $B'C_6H_4N_2O$. [141°].— $B'H_2PtCl_6$.

o-TOLYL-METHYL-THIOHYDANTOIN

$\text{HMe} \begin{smallmatrix} \text{CO} \cdot \text{N}(\text{C}_6\text{H}_5) \\ \text{NH} \cdot \text{CS} \end{smallmatrix}$ [198°]. Formed from *o*-tolyl-thiocarbimide and alanine (Marckwald, B. 24, 3281). Crystals.

p-Tolyl-methyl-thiohydantoin. [197°]. Formed in like manner from *p*-tolyl-thiocarbimide and alanine (Aschan, B. 17, 427). Minute prisms. On heating with alcoholic potash it is converted by hydrolysis into a salt of the oily $\text{NHC}_6\text{H}_4\text{CS.NH.CHMe.CO}_2\text{H}$, which slowly changes, in the free state, back into the hydantoin.

o-Tolyl-di-methyl-thiohydantoin

$\text{CMe}_2 \begin{smallmatrix} \text{CO} \cdot \text{N}(\text{C}_6\text{H}_5) \\ \text{NH} \cdot \text{CS} \end{smallmatrix}$ [175°]. Formed from *o*-tolyl-thiocarbimide and α -amido-isobutyric acid (Marckwald, B. 24, 3284). Needles, v. sol. hot alcohol.

p-Tolyl-di-methyl-thiohydantoin. [85°]. Formed in like manner from *p*-tolyl-thiocarbimide. Crystals, v. sol. most solvents.

o-TOLYL-METHYL-THIO-UREA

$\text{NHMe.CS.NHC}_6\text{H}_5$. [153°]. Formed from methyl-thiocarbimide and *o*-toluidine in alcohol (Dixon, C. J. 55, 622). Pearly crystals, m. sol. hot water, sol. alcohol.

p-Tolyl-methyl-thio-urea. [126°]. Formed in like manner from *p*-toluidine. Vitreous prisms, v. sol. hot water.

Reference.—TOLYL-THIO-UREA.

o-TOLYL-(α)-NAPHTHYLAMINE $\text{C}_{17}\text{H}_{15}\text{N}$ i.e. $\text{C}_6\text{H}_4\text{.NH.C}_6\text{H}_4\text{Me}$. [95°]. Formed by heating (α)-naphthol (1 mol.) with *o*-toluidine (2 mols.) and CaCl_2 (1 mol.) in sealed tubes at 290°, the yield being 37 p.c. of the theoretical amount (Friedländer, B. 16, 2084). Flat needles, v. sol. alcohol and ether.

o-Tolyl-(β)-naphthylamine $\text{C}_{16}\text{H}_{13}\text{NH.C}_6\text{H}_4\text{Me}$. [96°]. Formed by heating a mixture of (β)-naphthol with *o*-toluidine and CaCl_2 at 280°. Silvery plates (from ligroin), v. sol. alcohol.— $\text{B}^2\text{C}_6\text{H}_4\text{N}_2\text{O}$, [110°]. Reddish-brown needles.

Benzoyl derivative [118°]. Plates.

p-Tolyl-(α)-naphthylamine $\text{C}_{17}\text{H}_{15}\text{N}$. [79°]. (860° at 528 mm.). Formed by heating (α)-naphthol with *p*-toluidine and CaCl_2 at 280°, the yield being 50 p.c. Short prisms (from alcohol). Its solutions exhibit blue fluorescence.

p-Tolyl-(β)-naphthylamine. [104°]. Formed by heating *p*-toluidine hydrochloride with (β)-naphthol for 8 hours at 200° (Witt, B. 20, 578; cf. Friedländer, B. 16, 2078). Plates (from alcohol). Its solutions have violet-blue fluorescence. Dissolved in isozamyl alcohol it is reduced by Na to a hydride [44°] (Bamberger a. Müller, B. 22, 1809). With nitroso-dimethylaniline hydrochloride and HOAc it yields a safranin $\text{C}_{20}\text{H}_{19}\text{N}_3\text{O}(\text{C}_6\text{H}_5)\text{:O}_2\text{H.NMe}$ (Witt, B. 21, 724). *p*-Tolyl-naphthyl-amine (10 g.), heated with nitroso-dimethylaniline hydrochloride (4 g.), ZnCl_2 (10 g.), and HOAc (100 c.c.), forms $\text{C}_{20}\text{H}_{12}(\text{NH.C}_6\text{H}_4\text{Me})_2$ [225°], which yields an acetyl derivative [225°].

Acetyl derivative [85°]. Needles.**Benzoyl derivative** [189°]. Needles.**Reference.—TETRA-BROMO-TOLYL-NAPHTHYLAMINE.****DI-*p*-TOLYL-NAPHTHYLENE-DIAMINE**

$\text{C}_{16}\text{H}_{12}(\text{NHC}_6\text{H}_4)_2$. [287°]. Formed by heating di-*oxy*-naphthalene with *p*-toluidine and *p*-tolu-

idine hydrochloride (Annaheim, B. 20, 1878). Needles (from xylene). Gives a red colour on heating with solid ZnCl_2 .

o-TOLYL-(α)-NAPHTHYL-THIO-UREA

$\text{CS}(\text{NHC}_6\text{H}_5)(\text{NHC}_6\text{H}_4)$. [168°]. Formed by the action of *o*-tolyl thiocarbimide on (α)-naphthylamine or of (α)-naphthyl thiocarbimide on *o*-toluidine (Mainzer, B. 15, 1416). Short needles, sol. alcohol. Split up by conc. HClAq at 150° into *o*-toluidine, (α)-naphthylamine, *o*-tolyl-thiocarbimide, and (α)-naphthyl thiocarbimide.

o-Tolyl-(β)-naphthyl-thio-urea [194°]. Formed from *o*-tolyl thiocarbimide and (β)-naphthylamine (M.).

p-Tolyl-(α)-naphthyl-thio-urea [168°]. Formed from *p*-tolyl thiocarbimide and (α)-naphthylamine (M.). Slender white needles.

p-Tolyl-(β)-naphthyl-thio-urea [164°]. Formed from *p*-tolyl thiocarbimide and (β)-naphthylamine (M.). Decomposed by HClAq at 150° into *p*-toluidine, (β)-naphthylamine, *p*-tolyl thiocarbimide, and (β)-naphthyl thiocarbimide.

p-TOLYL p-NITRO-BENZYL OXIDE

$\text{C}_6\text{H}_4\text{Me.O.CH}_2\text{.C}_6\text{H}_4\text{.NO}_2$. [91°]. Formed from *p*-nitro-benzyl chloride and alcoholic $\text{C}_6\text{H}_5\text{ONa}$ (Frische, A. 224, 144). Yellowish plates, sol. ether.

TOLYL NITROSO-METHYL KETONE v.

Oxim of TOLYL-GLYOXAL.

TOLYL-OXAMIC ACID v. vol. iii. p. 654.**TOLYL-OXAMIDE v. OXALIC ACID.****o-TOLYL-OXAZOLINE** $\begin{smallmatrix} \text{CH}_2\text{.O} \\ \text{CH}_2\text{.N} \end{smallmatrix} > \text{C.C}_6\text{H}_4$.

(255°). Formed by dissolving *o*-toluic bromo-ethyl-amide in hot water and adding alkali (Salomon, B. 26, 1322). Oil. Evaporating with aqueous HCl (1 mol.) forms the compound $\text{C}_6\text{H}_4\text{.CO.O.CH}_2\text{.CH}_2\text{.NH}_2$, while excess of HCl gives $\text{C}_6\text{H}_4\text{.CO.NH.CH}_2\text{.CH}_2\text{Cl}$.— $\text{B}^1\text{C}_6\text{H}_4\text{N}_2\text{O}$, [145°].— $\text{B}^2\text{H}_2\text{PtCl}_6$, [189°].

p-Tolyl-oxazoline $\text{C}_6\text{H}_4\text{.NO}$. [66°]. (265°). Formed by decomposing $\text{C}_6\text{H}_4\text{.CO.NH.CH}_2\text{.CH}_2\text{Br}$ with alkali. Needles.— $\text{B}^1\text{C}_6\text{H}_4\text{N}_2\text{O}$, [188°].— $\text{B}^2\text{H}_2\text{PtCl}_6$, [186°].

DI-*o*-TOLYL OXIDE $(\text{C}_6\text{H}_4\text{Me})_2\text{O}$. *Cresyl ether*. (272°–278°). S.G. $^{24^\circ}$ 1.047. A product of the distillation of $\text{Al}(\text{OC}_6\text{H}_4\text{Me})_3$ (Gladstone a. Tribe, C. J. 49, 27). Oil, smelling like geranium leaves.

Di-*m*-tolyl oxide $(\text{C}_6\text{H}_4)_2\text{O}$. (284°–288°). μ , 1.5576 at 16°. V.D. 193.9. A product of distillation of aluminium thymol $\text{Al}(\text{OC}_6\text{H}_3)_3$ (Gladstone a. Tribe, C. J. 41, 18). Oil.

Di-*p*-tolyl oxide $(\text{C}_6\text{H}_4)_2\text{O}$. [50°]. (270°–300°). Formed by distilling aluminium *p*-cresol (G. a. T.). Prisms (from alcohol).

Isomeride [165°]. Formed by heating *p*-cresol with ZnCl_2 (Busch, B. 17, 2638). Crystals, volatile with steam.

DI-TOLYL-OXINDOLE $\text{C}_6\text{H}_4 \begin{smallmatrix} \text{O}(\text{C}_6\text{H}_5) \\ \text{NH} \end{smallmatrix} > \text{CO}$

Toluisatin. [200°]. Formed by adding toluene to a solution of isatin in H_2SO_4 (Baeyer a. Lazarus, B. 18, 2638). Needles, v. sol. alcohol and ether, sol. aqueous alkalis. Yields an acetyl derivative $\text{C}_{20}\text{H}_{15}\text{O}(\text{NAc})$ [148°] and an ethyl derivative $\text{C}_{20}\text{H}_{15}\text{O}(\text{NEt})$ [108°], both being crystalline.

TOLYL-OXY-ACETIC ACID *v.* **Tolyl derivative of GLYCOLLIC ACID and OXY-TOLYL-ACETIC ACID.**

***p*-TOLYL OXY-ETHYL SULPHONE**

$C_8H_7SO_2CH_2CH_2OH$. [55°]. Got from sodium toluene *p*-sulphinate and glycol chlorhydrin (Otto, *J. pr.* [2] 30, 355). Needles (from alcohol) with bitter taste. Heating with KOH aq gives $C_8H_7S_2O_4$. [84°].

Benzoyl derivative $C_8H_7SO_2C_2H_5OBz$. [176°]. Needles, sl. sol. hot alcohol.

DI-*o*-TOLYL-PARABANIC ACID $C_{17}H_{11}N_2O_4$

i.e. $CO \begin{smallmatrix} N(C_6H_4)CO \\ N(C_6H_4)CO \end{smallmatrix}$ [203°]. Formed by boiling an alcoholic solution of oxalyl-di-tolyl-guanidine with conc. HCl aq (Berger, *B.* 12, 1856). Small needles.

Di-*p*-tolyl-parabanic acid [144°]. Formed by boiling di- (or tri-) *p*-tolyl-guanidinedicyanide with alcohol and HCl (Landgrebe, *B.* 11, 978). Plates. Oxidised by potassium permanganate to $CO \begin{smallmatrix} N(C_6H_4CO_2H)CO \\ N(C_6H_4CO_2H)CO \end{smallmatrix}$ [159°?].

***p*-TOLYL PENTADECYL KETONE**

$C_{15}H_{31}CO_2C_6H_4Me$. [60°]. (262° at 15 mm.). Formed from palmityl chloride, toluene, and $AlCl_3$ (Kraft, *B.* 21, 2266). Needles (from alcohol). Yields *p*-toluic acid on oxidation.

***o*-TOLYL-PENTHAZOLINE** $C_{11}H_{13}NS$ *i.e.*

$C_6H_4CS-CH_2-NCH_2CH_2$. Got by heating trimethylene chlorobromide with thio-*o*-toluic amide (Pinkus, *B.* 26, 1081). Oil, volatile with steam. Its hydrochloride gives a white compound with $HgCl_2$.

***p*-Tolyl-pentiazoline** [53°].

***p*-TOLYL-PENTRIAZINE. Dihydride**

$C_6H_4 \begin{smallmatrix} N=N \\ CH_2NCH_2 \end{smallmatrix}$ [151°]. Formed by the action of HNO_2 on *o*-amido-benzyl-*p*-toluidine hydrochloride (Busch, *B.* 25, 450). Yellow plates (from alcohol).— $B'HCl-B'_2H_2PtCl_6$. [190°].— $B'C_6H_4N_3O$. [182°]. Dark-yellow needles.

***p*-TOLYL-PHENYL-ACETAMIDINE** $C_{15}H_{13}N_2$ *i.e.* $C_6H_5CH_2C(NC_6H_4Me)NH_2$. [119°]. Formed by heating phenyl-acetonitrile with *p*-toluidine hydrochloride (Bernthsen, *A.* 184, 342). Crystals (from alcohol).— $B'_2H_2PtCl_6$: yellow prisms.

DI-*p*-TOLYL-DIPHENYLACETYLENE-DIAMINE $C_{26}H_{21}N_2$ *i.e.* $C_6H_4N:CPH:CPh:NC_6H_4$. [161°]. Formed, together with $BzCPh:NC_6H_4$, [116°], by heating benzil (1 mol.) with *p*-toluidine (2 mols.) at 180° (Bandrowski, *M.* 9, 690). Triclinic plates.

DI-TOLYL-PHENYLENE-DIAMINE *v.* **PHENYLENE-DI-TOLYL-DIAMINE.**

TOLYL PHOSPHATES.

Tri-*o*-tolyl-phosphate $(C_6H_4O)PO$. Formed by heating *o*-resol with $POCl_3$, the yield being 95 p.c. (Heim, *B.* 16, 1767; Rapp, *A.* 224, 173). Oil, sol. alcohol and ether.

***p*-Tolyl phosphate** $PO(OC_6H_4)(OH)$. [116°]. Formed by the action of water on $PO(OC_6H_4)Cl_2$, which is a product of the action of $POCl_3$ on *p*-resol (Rapp, *A.* 224, 163). Plates, sol. alcohol, ether, and water.

Tri-*p*-tolyl phosphate $PO(OC_6H_4)_3$. [78°]. Formed by heating *p*-resol with $POCl_3$, the yield being 95 p.c. Colourless tables, insol. Aq.

***p*-TOLYL-PHOSPHINE** $C_6H_4NH_2$. [4°]. (178°). Formed by the action of $AlCl_3$ on a mixture of toluene and PCl_3 , the resulting

$C_6H_5PCl_2$ [20°] (245°), being converted by water into $C_6H_5P(OH)_2$, which splits up on heating into tolyl-phosphine and toluene phosphonic acid $C_6H_5PO_3H_2$ (Michaelis, *B.* 12, 1009; 13, 653; *A.* 212, 230). Oil with strong odour. Rapidly oxidised by air to $C_6H_5P(OH)_2$. HI forms $C_6H_5PH_2I$, crystallising in colourless needles.

***p*-TOLYL-PHTHALIDE** $C_{15}H_{11}O_2$ *i.e.*

$C_6H_4 \begin{smallmatrix} CO \\ CH(C_6H_4)O \end{smallmatrix}$. [129°]. Formed by reducing $C_6H_4CO_2C_6H_4CO_2H$ in alcoholic solution with Zn and HCl (Gresly, *A.* 234, 235). Needles, sol. hot alcohol, insol. NH_4Aq .

Di-*p*-tolyl-phthalide $C_{18}H_{13}O_2$ *i.e.*

$C_6H_4 \begin{smallmatrix} CO \\ C(C_6H_4)O \end{smallmatrix}$. [116°]. Formed by heating phthalyl chloride (100 g.) with toluene (450 g.) and $AlCl_3$ (Berchem, *B.* [2] 42, 168; cf. Friedel a. Crafts, *B.* [2] 35, 505). Prisms, sol. alcohol and ether.

TOLYL-PHTHALIMIDE *v.* **Tolylimide of PHTHALIC ACID.**

***m*-TOLYL-PROPIOLIC ACID** $C_8H_7C:CHCO_2H$. [109.5°]. Formed by boiling di-bromo-tolyl-propionic acid $C_8H_7CHBr.CHBr.CO_2H$ with alcoholic potash (Müller, *B.* 20, 1215). $AgNO_3$ gives an explosive white pp.

***o*-TOLYL-PROPIONIC ACID** $C_8H_7C_2H_3O_2$

Monoclinic prisms (Young, *B.* 25, 2102). ***m*-Tolyl-propionic acid** $C_8H_7CH_2CH_2CO_2H$. [43°]. Formed by reducing *m*-tolyl-acrylic acid with sodium-amalgam (Müller, *B.* 20, 1214; von Miller, *B.* 23, 1899). Needles (from ligroin), sol. water, alcohol, and ether. Volatile with steam.

***m*-Tolyl-propionic acid** [125°]. Formed by oxidation of *m*-isobutyl-toluene by HNO_3 (Effront, *B.* 17, 2330). Needles, sl. sol. hot water.— AgA' : crystals, sol. hot water.

***p*-Tolyl-propionic acid**. [116°] (Von Müller, *B.* 23, 1898); [120°] (Kröber, *B.* 23, 1033). Formed by reducing *p*-tolyl-acrylic acid. Condensed by hot H_2SO_4 to oxy-methyl-indonaphthene.

Di-*a*-tolyl-propionic acid $CH_3C(C_6H_4)_2CO_2H$. [152°]. Prepared by adding toluene to a solution of pyruvic acid in H_2SO_4 at -10° (Böttlinger, *B.* 14, 1596; 15, 1474). Monoclinic crystals, sol. hot alcohol. Give *u*-di-tolyl-ethane on distillation with lime. Oxidised by $KMnO_4$ to di-phenyl-ethane tri-carboxylic acid.— AgA' .

Ethyl ether EtA' . [145°]. Prisms.

References.—Bromo-, Nitro-, and Oxy-, TOLYL-PROPIONIC ACIDS.

***p*-TOLYL-PROPIONIC ALDEHYDE**

$C_8H_7CH_2CH_2CHO$. (228°). S.G. d_{20}^{20} 0.941. Formed by the action of water on the compound of CrO_2Cl_2 with the cymene got from camphor and P_2O_5 (Richter a. Schöthner, *B.* 17, 1981). Got also by distilling calcium *p*-tolyl-propionate with calcium formate (Miller, *B.* 23, 1082). Oil, smelling like peppermint. Volatile with steam. Yields *p*-toluic and terephthalic acids on oxidation.

DI-*o*-TOLYL-PROPYLENE-DIAMINE

$CHMe(NHC_6H_4)_2CH_2NHC_6H_4$. (280° at 120 mm.). Got by heating *o*-toluidine with propylene bromide (Bischoff, *B.* 25, 8276).

Acetyl derivative $C_{25}H_{19}N_2O_2$. [120°].

Di-*p*-tolyl-propylene-diamine

$C_8H_7(NHC_6H_4)_2$. (277° at 48 mm.) (Bischoff, *B.* 25, 8277). Got from *p*-toluidine and C_2H_5Br . Oil.

Acetyl derivative $C_{21}H_{22}N_2O_2$. [114°].

Benzoyl derivative $C_{23}H_{24}N_2O_2$. [152°].

o-TOLYL-PROPYLENE-ψ-THIO-UREA

$C_8H_9NH.C \begin{smallmatrix} \text{S} \\ \text{CHMe} \\ \text{N} \end{smallmatrix} \begin{smallmatrix} \text{CH}_2 \\ \text{CH}_2 \end{smallmatrix}$. [126°]. Formed from

s-o-tolyl-allyl-thio-urea and HCl (Prager, B. 22, 2999). Tables, sl. sol. hot water.— $B'_2H_2PtCl_6$. [178°]. Prisms.— $B'_2C_6H_5N_2O_2$. [176°]. Cubes.

DI-o-TOLYL-PROPYLENE UREA

$C_8H_9 \begin{smallmatrix} \text{NC}_6H_5 \\ \text{NC}_6H_5 \end{smallmatrix} > CO$. [93°]. Formed from di-o-tolyl-propylene-diamine and $COCl_2$ (Bischoff, B. 25, 3276). Prisms (from dilute alcohol).

Di-p-tolyl-propylene-urea. [130°].

d-TOLYL ISOPROPYL KETONE

$C_8H_9Me.CO.Pr$. (236°). Formed from toluene, isobutyl chloride and $AlCl_3$ (Claus, *J. pr.* [2] 46, 480). Oil, with bitter taste and aromatic odour. Yields *p*-toluic and terephthalic acids on oxidation. Yields an oxim [92°]. May be reduced to *p*-tolyl-isopropyl-carbinol; an oil boiling above 300°.

DI-o-TOLYL-PYRAZINE HEXAHYDRIDE

$C_8H_9Me.N \begin{smallmatrix} \text{CH}_2 \text{CH}_2 \\ \text{CH}_2 \text{CH}_2 \end{smallmatrix} > N.C_6H_5Me$. *Di-o*-tolyl-piperazine. [171°]. Formed from ethylene bromide, *o*-toluidine, and Na_2CO_3 at 160° (Bischoff, B. 22, 1781; 23, 1982; cf. Mauthner & Suida, *M.* 7, 233). Crystals (from ether).

Isomeride. [154°]. Formed by heating di-o-tolyl-ethylene-diamine with chloro-acetic acid and $NaOAc$ (Bischoff, B. 23, 2031). Thin needles (from alcohol).

Di-p-tolyl-pyrazine hexahydride

$C_8H_9.N \begin{smallmatrix} \text{CH}_2 \text{CH}_2 \\ \text{CH}_2 \text{CH}_2 \end{smallmatrix} > N.C_6H_5$. [188°]. Formed from *p*-toluidine and $C_2H_5Br_2$ in presence of $NaOAc$ or Na_2CO_3 . Prisms, sl. sol. alcohol. With $NaNO_2$ and $HOAc$ it yields a di-nitroso-derivative [167°].

o-TOLYL-PYRAZOLE $CH \begin{smallmatrix} \text{CH} \cdot N \cdot C_6H_5Me \\ \text{CH} \cdot N \end{smallmatrix}$

(246·5° cor.). S.G. $\frac{2}{3}$ 1·0868; $\frac{1}{3}$ 1·0753. Formed by boiling epichlorhydrin (1 mol.) with *o*-tolyl-hydrazine (2 mols.) and benzene, boiling off the benzene, and heating the residue at 150° (Balbiano, *G.* 18, 368). Not reduced by boiling with alcohol and Na .— $B'_2H_2PtCl_6$. [201°].— $B'EtI$. [100°]. Needles, v. e. sol. water.

Dihydrate $C_8H_9N_2C_6H_5$. (271°). S.G. $\frac{2}{3}$ 1·084. Formed from acrolein tolyl-hydrazide and dilute (2 p.c.) H_2SO_4 . Oil. Sol. fuming $HClAq$, but reppd. by water. $K_2Cr_2O_7$ and H_2SO_4 give an indigo-blue colour.

p-Tolyl-pyrazole. [33°]. (259° cor.). Formed, in like manner, from epichlorhydrin and *p*-tolyl-hydrazine. Yellowish plates, sl. sol. hot water.— $B'_2H_2PtCl_6$ 2aq: needles. [184°].— $B'EtI$. [105°]. Prisms, v. sol. water.

Dihydrate. [60·5°]. (282° i.v.). Formed from acrolein *p*-tolyl-hydrazide and dilute H_2SO_4 . Got also by reducing *p*-tolyl-pyrazole in alcoholic solution by Na . Iridescent plates, sl. sol. hot water. Its acidified solution is coloured violet-red by $K_2Cr_2O_7$.

p-TOLYL-PYRIDINE HEXAHYDRIDE

$C_8H_9Me.N.C_5H_5$. (262°). Formed by heating piperidine with *p*-bromo-toluene at 270° (Lellmann & Just, B. 24, 2099). V. sol. alcohol and benzene.

p-TOLYL-PYRROLE $C_{11}H_{11}N$ i.e.

$\begin{smallmatrix} \text{CH} \cdot \text{CH} \\ \text{CH} \cdot \text{CH} \end{smallmatrix} > NC_6H_5Me$. Got by dry distillation of *p*-toluidine mucate (Lichtenstein, B. 14, 933). Converted by $AcCl$ into crystalline $C_8H_9NC_6H_5Ac$.— B'_2HgCl_2 .

Di-p-tolyl-pyrrole $\begin{smallmatrix} \text{CH} \cdot \text{C}(\text{C}_6\text{H}_5) \\ \text{CH} \cdot \text{C}(\text{C}_6\text{H}_5) \end{smallmatrix} > NH$.

[197°]. Formed by treating di-*p*-tolyl-furfuran or $(C_6H_7.CO)_2C_6H_5$ with NH_4OAc (Holleman, *R. T. C.* 6, 73). Small plates with bluish lustre. Does not form a K derivative. Boiling $HClAq$ gives a red resin. With isatin, after several days, it gives an intense red colour.

o-TOLYL-QUINAZOLINE DIHYDRIDE

$C_{11}H_{11}N_2$ i.e. $C_8H_9 \begin{smallmatrix} \text{N} = \text{CH} \\ \text{CH}_2 \cdot \text{N} \cdot \text{C}_6H_5Me \end{smallmatrix}$. Formed by reducing the formyl derivative of *o*-nitro-benzyl-*o*-toluidine with tin and $HClAq$ (Paal & Busch, B. 22, 2701). Oil.— $B'HsSnCl_3$.— $B'HCl$: amorphous.— $B'_2H_2PtCl_6$. [210°]. Needles (from alcohol containing HCl).

p-Tolyl-quinazoline dihydride. [120°]. Formed in like manner. Plates, v. sol. alcohol.— $B'HsSnCl_3$. [165°].— $B'HCl$ 2aq. [85°].— $B'HCl$. [251°].— $B'_2H_2PtCl_6$. [216°]. Yellow needles.

Methylo-iodide $B'MeI$. [186°]. Needles.

p-Tolyl-quinazoline tetrahydride

$C_8H_9 \begin{smallmatrix} \text{NH} \cdot \text{CH}_2 \\ \text{CH}_2 \cdot \text{N} \cdot \text{C}_6H_5Me \end{smallmatrix}$. [127°]. Formed by reducing the dihydride in alcoholic solution by sodium. Needles, m. sol. alcohol. Yields a nitrosamine [100°]. Yields a crystalline hydrochloride.

Reference.—OXY-TOLYL-QUINAZOLINE.

(Py. 3)-o-TOLYL-QUINOLINE $C_{16}H_{11}N$ i.e.

$C_8H_9 \begin{smallmatrix} \text{CH} \cdot \text{CH} \\ \text{N} = \text{C} \cdot \text{O} \cdot \text{C}_6H_5Me \end{smallmatrix}$. [77°]. Formed by distilling oxy-tolyl-quinoline (pseudoflavenol) with zinc-dust (Weidel & Bamberger, M. 9, 108). Silky needles (from benzene).— $B'_2H_2PtCl_6$ (dried at 105°). Orange tables.

m-Tolyl-isoquinoline $C_8H_9 \begin{smallmatrix} \text{CH} \cdot \text{C} \cdot \text{C}_6H_5 \\ \text{CH} \cdot \text{N} \end{smallmatrix}$.

[52°]. Formed by heating (1)-chloro- (3)-*m*-tolyl-isoquinoline with HI and P for three hours at 170° (Heilmann, B. 23, 3168). Needles (from $MeOH$).

p-Tolyl-isoquinoline $C_8H_9 \begin{smallmatrix} \text{CH} \cdot \text{C} \cdot \text{C}_6H_5 \\ \text{CH} \cdot \text{N} \end{smallmatrix}$.

[78°]. Formed in like manner (Ruhemann, B. 24, 3975). Needles.— $B'HI$.— $B'H_2CrO_4$.— $B'_2H_2PtCl_6$.— $B'_2C_6H_5N_2O_7$. Yellow needles.

Reference.—OXY-TOLYL-QUINOLINE.

TETRA-m-TOLYL-SILICANE $Si(C_8H_9)_4$

[151°]. (above 550°). S.G. $\frac{20}{22}$ 1·1188. Formed from *m*-bromo-toluene, $SiCl_4$, and sodium (Polis, B. 19, 1021). Prisms (from ether), v. sol. benzene.

Tetra-p-tolyl-silicane $Si(C_8H_9)_4$. [228°]. (above 450°). S.G. $\frac{22}{22}$ 1·0793. Formed from $SiCl_4$, *p*-bromo-toluene, ether, Na , and a little $EtOAc$ (Polis, B. 18, 1542; 19, 1019). Monoclinic crystals (from chloroform). Decomposed by conc. HNO_3 , forming silica and di-*p*-nitro-toluene [72°].

TETRA-o-TOLYL SILICATE $Si(OC_8H_9)_4$ (c. 437°). Formed by heating *o*-cresol with $SiCl_4$, the yield being 90 p.c. of the theoretical quantity (Hertkorn, B. 18, 1886). Oil, v. sol.

alcohol. Decomposed by hot water into silica and *o*-cresol.

Tetra-*m*-tolyl silicate $\text{Si}(\text{OC}_6\text{H}_4)_4$. (445°) at 720 mm. Syrup (H.).

Tetra-*p*-tolyl silicate $\text{Si}(\text{OC}_6\text{H}_4)_4$. [70°]. (444°). Tables or prisms, v. sol. benzene (H.).

***p*-TOLYL SILICO-CHLORIDE** $\text{C}_6\text{H}_4\text{SiCl}_3$. (219°). Formed from $\text{Hg}(\text{C}_6\text{H}_5)_2$ and SiCl_4 at 310° (Ladenburg, A. 173, 165). Liquid, converted by dilute aqueous ammonia into $\text{C}_6\text{H}_4\text{SiO.OH}$ [c. 150°], which is converted at 200° into solid $(\text{C}_6\text{H}_4\text{SiO})_2\text{O}$.

TOLYL SULPHATES.

***o*-Tolyl sulphuric acid**

[1:2] $\text{C}_6\text{H}_4\text{Me.O.SO}_2\text{OH}$. Occurs in small quantity in the urine of horses (Preusse, H. 2, 355). Prepared from $\text{C}_6\text{H}_4\text{Me.OK}$ and $\text{K}_2\text{S}_2\text{O}_7$ (Baumann, B. 11, 1911). The K salt crystallises in plates, m. sol. water.

***m*-Tolyl sulphuric acid** $\text{C}_6\text{H}_4\text{Me.O.SO}_2\text{OH}$. Occurs in very small quantity in horses' urine (P.).

***p*-Tolyl sulphuric acid** $\text{C}_6\text{H}_4\text{Me.O.SO}_2\text{OH}$. Occurs in the urine of horses and cows (Baumann, R. 9, 1389, 1716; Städeler, A. 77, 18). Formed by boiling potassium *p*-cresol with $\text{K}_2\text{S}_2\text{O}_7$. The K salt is sl. sol. cold alcohol.

DI-*o*-TOLYL-SULPHAZIDE $\text{C}_6\text{H}_4\text{N}_2\text{SO}_2$ *i.e.* [2:1] $\text{C}_6\text{H}_4\text{Me.NH.NH.SO}_2\text{C}_6\text{H}_4\text{Me}$ [1:2]. *Tolyl-toluene-sulphazide*. [142°]. Obtained by the action of SO_2 upon *o*-diazotoluene in alcoholic solution. White glistening needles (Limpricht, B. 20, 1241). When boiled with baryta-water it decomposes into *o*-toluene-sulphinic acid, toluene, and nitrogen.

Di-*p*-tolyl-sulphazide $\text{C}_6\text{H}_4\text{N}_2\text{SO}_2$ *i.e.* [4:1] $\text{C}_6\text{H}_4\text{Me.NH.NH.SO}_2\text{C}_6\text{H}_4\text{Me}$ [1:4]. *Tolyl-toluene-sulphazide*. [140°]. Formed in like manner from *p*-diazotoluene (L.). Small needles. By boiling with baryta-water it is decomposed into *p*-toluene-sulphinic acid, toluene, and nitrogen.

Reference.—NITRO-DI-TOLYL-SULPHAZIDE.

DI-*p*-TOLYL SULPHIDE $\text{S}(\text{C}_6\text{H}_4\text{Me})_2$. [57°]. (above 300°). Formed by distillation of lead *p*-tolyl-mercaptide (Otto, B. 12, 1175). Small needles, insol. water, sol. alcohol. Yields di-*p*-tolyl sulphone on oxidation by KMnO_4 .

Di-*m*-tolyl disulphide $\text{C}_6\text{H}_4\text{S}_2$ *i.e.* $(\text{C}_6\text{H}_4\text{Me})_2\text{S}_2$. Formed from *m*-tolyl mercaptan by treatment with dilute HNO_3 (Hübner a. Post, A. 169, 51). Liquid at -22°. Decomposed on boiling or by atmospheric oxidation of its ammoniacal alcoholic solution (Leuckart, J. pr. [2] 41, 189).

Di-*p*-tolyl disulphide $(\text{C}_6\text{H}_4\text{Me})_2\text{S}_2$. [43°]. Formed from *p*-tolyl mercaptan by atmospheric oxidation (Märcker, A. 136, 88) or by the action of ClSO_3H (Beckurts a. Otto, B. 11, 2066), or by treatment with ICy (Thurnauer, B. 23, 769). Formed also by the action of H_2S on a warm dilute solution of toluene *p*-sulphinic acid in alcohol (Otto, J. pr. [2] 37, 211). Crystals, v. e. sol. ether. Begins to boil at 307° i.v. but decomposes, on distillation. Alcoholic K₂S forms *p*-tolyl mercaptan (Otto a. Rössing, B. 19, 3129).

Di-*p*-tolyl tetrasulphide $(\text{C}_6\text{H}_4\text{Me})_2\text{SO}_4$. [75°]. Formed by the action of H_2S on a conc. solution of toluene *p*-sulphinic acid (Otto, J. pr.

[2] 37, 211). Small plates, insol. water, v. sol. ether.

References.—DI-AMIDO-, DI-BROMO-, and OXY-DI-TOLYL-SULPHIDE.

***o*-TOLYL SULPHOCYANIDE** $\text{C}_6\text{H}_4\text{Me.S.CN}$. (c. 245°). Formed by adding cuprous sulphocyanide in KSCy to a solution of *o*-diazotoluene (Thurnauer, B. 23, 770). Yellowish-red oil with unpleasant odour.

***p*-Tolyl sulphocyanide**. (c. 248°). Formed in like manner, and also by passing CyCl through alcohol containing lead *p*-tolyl mercaptide. Liquid, solidifying below 0°.

DI-*p*-TOLYL SULPHONE $(\text{C}_6\text{H}_4\text{Me})_2\text{SO}_2$. [158°]. (405°) at 714 mm. Prepared by the action of AlCl_3 on a mixture of toluene and toluene *p*-sulphonic chloride (Beckurts a. Otto, B. 11, 2068; 12, 1177; cf. Michael, B. 10, 584). Formed by the action of fuming H_2SO_4 or SO_3 on toluene (Deville, A. 44, 306; Otto a. Grüber, A. 154, 193) and by the action of KMnO_4 and HOAc on di-*p*-tolyl sulphide. Prisms (from benzene), sl. sol. cold alcohol and ether. Potash-fusion yields *p*-cresol and diphenyl (Otto, B. 19, 2426).

DITOLYL DISULPHONIC ACID

[1:4:5] $\text{C}_6\text{H}_4\text{Me}(\text{SO}_3\text{H})_2\text{C}_6\text{H}_4\text{Me}(\text{SO}_3\text{H})_2$ [5:1:4]. Formed from di-amido-ditolyl disulphonic acid by diazotisation followed by boiling with alcohol (Halle, A. 270, 363). Crystals, v. e. sol. water, m. sol. alcohol, insol. ether.—K₂A''. Hexagonal plates.—KHA'': prisms.—BaA'' 5aq.

Chloride $\text{C}_6\text{H}_4\text{Me}_2\text{S}_2\text{O}_6\text{Cl}_2$. [229°].

Amide $\text{C}_6\text{H}_4\text{Me}_2\text{S}_2\text{O}_6(\text{NH}_2)_2$. Needles.

***p*-TOLYL-SULPHONO-ACETIC ACID**

$\text{C}_6\text{H}_4\text{Me.SO}_2\text{CH}_2\text{CO}_2\text{H}$. [118°]. Formed from sodium benzene sulphinate and chloro-acetic acid (Gabriel, B. 14, 834). Crystals (from benzene), sl. sol. hot water. Cl passed into its aqueous solution forms $\text{C}_6\text{H}_4\text{Me.SO}_2\text{CHCl}_2$ [114°]. Br forms $\text{C}_6\text{H}_4\text{Me.SO}_2\text{CHBr}_2$ and $\text{C}_6\text{H}_4\text{Me.SO}_2\text{CHBr}$ (Otto, J. pr. [2] 40, 542).—AgA': trimetric tables.

Ethyl ether EtA'. Converted by bromine (2 mols.) at 90° into $\text{C}_6\text{H}_4\text{Me.SO}_2\text{CBr}_2\text{CO}_2\text{Et}$ which on saponification by cold NaOHAq yields $\text{C}_6\text{H}_4\text{Me.SO}_2\text{CHBr}_2$ [117°].

***p*-TOLYL-SULPHONO-ACETONE**

$\text{CH}_3\text{CO.CH}_2\text{SO}_2\text{C}_6\text{H}_4\text{Me}$. [51°]. Formed by heating sodium toluene *p*-sulphinate with chloro-acetone in alcohol (Otto, J. pr. [2] 36, 425). Needles, v. sol. alcohol. Bromine forms $\text{CH}_2\text{Br.CO.CH}_2\text{SO}_2\text{C}_6\text{H}_4\text{Me}$ [130°], m. sol. alcohol.

Di-*p*-tolyl-di-sulphono-acetone

$\text{CO}(\text{CH}_2\text{SO}_2\text{C}_6\text{H}_4\text{Me})_2$. Formed by heating $\text{CH}_2\text{Br.CO.CH}_2\text{SO}_2\text{C}_6\text{H}_4\text{Me}$ with sodium toluene *p*-sulphinate in alcoholic solution. Plates, v. sol. hot HOAc and chloroform.

DI-TOLYL DI-SULPHONO-DI-ETHYL-AMINE $\text{NH}(\text{C}_6\text{H}_4\text{Me})_2\text{SO}_2\text{C}_2\text{H}_5$. Formed by heating di-tolyl ethylene disulphone with NH_4Aq (Otto, J. pr. [2] 30, 359).—B'HCl. [201°].—B'HAuCl₃: dark-yellow needles.

DI-TOLYL-DI-SULPHONO-DI-ETHYL OXIDE $\text{O}(\text{C}_6\text{H}_4\text{Me})_2\text{SO}_2\text{C}_2\text{H}_5$. [84°]. Formed by the action of conc. KOHAq on $\text{C}_6\text{H}_4(\text{SO}_2\text{C}_2\text{H}_5)_2$ and as a by-product in the preparation of $\text{C}_6\text{H}_4\text{Me.SO}_2\text{C}_2\text{H}_4\text{OH}$ [55°] by the action of dilute KOHAq on the same body (Otto a. Tröger, B. 26, 944; cf. J. pr. [2] 80, 171, 321).

TOLYL DISULPHOXIDE *v. Tolyl ether of Toluene thiosulphonic acid*.

Di-*p*-tolyl sulphoxide $\text{SO}(\text{C}_6\text{H}_4\text{Me})_2$. [92°]. Formed from toluene, SOCl_2 , and AlCl_3 (Parker, B. 23, 1844). Flat needles (from ligroin), v. e. sol. benzene. Reduced by sodium and alcohol to di-tolyl sulphide [56°]. KMnO_4 in HOAc forms di-tolyl sulphone [158°].

DI-*o*-TOLYL-TETRAZINE $\text{C}_6\text{H}_4\text{N}_4$, i.e.

$\text{C}_6\text{H}_4\text{N} \begin{smallmatrix} \text{N:CH} \\ \text{CH:N} \end{smallmatrix} \text{NC}_6\text{H}_4$. [141°]. Formed from *o*-tolyl-hydrazine, chloroform, and alcoholic potash (Buhemann, C. J. 57, 52). Crystals. Yields crystalline $\text{C}_6\text{H}_4(\text{SO}_3\text{H})\text{N}_4$ and $\text{C}_6\text{H}_4(\text{NO}_2)_2\text{N}_4$ [207°].— $\text{B}'\text{HCl}$: needles.

Methylo-iodide B'MeI . [198°]. Nodules.

Di-*p*-tolyl-tetrazine $\text{C}_6\text{H}_4\text{N}_4$. Formed in like manner. B'HCl : very unstable white needles.

Methylo-iodide B'MeI . [242°]. Needles.

***o*-TOLYL-THIAZOLE DIHYDRIDE**

$\text{C}_6\text{H}_4\text{Me.C} \begin{smallmatrix} \text{N.CH}_2 \\ \text{S.CH}_2 \end{smallmatrix}$ (282°). Formed from thio-*o*-toluic amide and ethylene bromide (Gabriel a. Heymann, B. 24, 786). Got also by heating *o*-toluic bromo-ethyl-amide with P_2S_5 (Salomon, B. 26, 1329). Converted by bromine-water into taurine and *o*-toluic acid.— $\text{B}'_2\text{H}_2\text{PtCl}_4$. [199°].— $\text{B}'\text{C}_6\text{H}_4\text{N}_4\text{O}_2$. [182°].

***p*-Tolyl-thiazole dihydride**. [81°]. Prepared in like manner. Tables.

***p*-TOLYL-THIOBIURET** $\text{C}_6\text{H}_4\text{N}_4\text{S}_2$. [158°]. Formed by fusing *p*-toluidine (2 pts.) with persulphocyanic acid (1 pt.) (Tursini, B. 17, 584). Minute needles, sol. NaOHAq . Yields $\text{C}_6\text{H}_4\text{N}_4\text{S}_2\text{Et}$ [184°], crystallising from alcohol in needles, and $\text{C}_6\text{H}_4\text{AcN}_4\text{S}_2$ [166°], crystallising in needles.

***o*-TOLYL- β -THIOCARBAMIC ACID**

[1:2] $\text{C}_6\text{H}_4\text{Me.NH.CS.OH}$. **Ethyl ether** $\text{C}_6\text{H}_4\text{N:C}(\text{SH}).\text{OEt}$. **Tolyl-thio-urethane**. Formed by heating *o*-tolyl-thiocarbimide with alcohol at 130° (Liebermann a. Natanson, B. 13, 1576; A. 207, 161). Oil, sol. alkalis.— $\text{C}_6\text{H}_4\text{AgNSO}$: white pp. insol. NH_4Aq . Converted by MeI into $\text{C}_6\text{H}_4\text{N}(\text{OEt})\text{SMe}$, and by EtI into $\text{C}_6\text{H}_4\text{N}(\text{OEt})\text{SEt}$, both being oils boiling above 250°.

***m*-Tolyl- β -thiocarbamic acid**

[1:3] $\text{C}_6\text{H}_4\text{Me.NH.CS.OH}$. **Ethyl ether** $\text{C}_6\text{H}_4\text{N:C}(\text{SH}).\text{OEt}$. [68°]. Formed in like manner (L. a. N.). Yields $\text{C}_6\text{H}_4\text{AgNSO}$ and oily $\text{C}_6\text{H}_4\text{EtNSO}$.

***p*-Tolyl- β -thiocarbamic acid**. **Ethyl ether** $\text{C}_6\text{H}_4\text{NC}(\text{SH}).\text{OEt}$. [87°]. Formed in the same way (L. a. N.). Triclinic crystals. Ammoniacal AgNO_3 added to its alcoholic solution ppts. $\text{C}_6\text{H}_4\text{NC}(\text{OEt})\text{SAg}$, which is converted by MeI into $\text{C}_6\text{H}_4\text{NC}(\text{OEt})\text{SMe}$, and by EtI into $\text{C}_6\text{H}_4\text{NC}(\text{OEt})\text{SEt}$, both being oils boiling above 250°. $\text{C}_6\text{H}_4\text{NC}(\text{OEt})\text{SEt}$ is decomposed by dilute H_2SO_4 at 180° into *p*-toluidine and thiocarbonic ether.

***o*-Tolyl- α -thiocarbamic acid** $\text{C}_6\text{H}_4\text{NH.CO.SH}$.

Methyl ether MeA' . [70°]. Formed by heating $\text{C}_6\text{H}_4\text{NH.C}(\text{NC}_6\text{H}_4)\text{SMe}$ with dilute H_2SO_4 at 140° (Will a. Bielschowski, B. 15, 1317). Plates.

Ethyl ether EtA' . [60°]. Tables.

***p*-Tolyl- α -thiocarbamic acid** $\text{NH}_2\text{C}_6\text{H}_4\text{CO.SH}$.

Methyl ether MeA' . [107°]. Formed by heating $\text{C}_6\text{H}_4\text{NH.C}(\text{NC}_6\text{H}_4)\text{SMe}$ with dilute H_2SO_4 at 170°. Needles, v. sol. alcohol and ether.

Ethyl ether EtA' . [79°]. Formed from

p-toluidine and Cl.CO.SET . Needles. Yields EtSH and tolyl cyanate on distillation.

Ethylene derivative

$\text{CO} \begin{smallmatrix} \text{N}(\text{C}_6\text{H}_4) \\ \text{S} \end{smallmatrix} \text{C}_6\text{H}_4$. [88°]. Long slender needles.

***o*-Tolyl-di-thio-carbamic acid**

$\text{C}_6\text{H}_4\text{NH.CS.SH} \cdot \text{NiA'}$. Brown needles, insol. water.— BaA' . Plates (Losanitsch, B. 24, 3027). Forms di-*o*-tolyl-thio-urea on heating.

Methyl ether MeA' . [132°]. Formed from the Ba salt and MeI . White needles.

Ethyl ether EtA' . [72°]. Formed by heating $\text{C}_6\text{H}_4\text{NH.C}(\text{NC}_6\text{H}_4)\text{SEt}$ with CS_2 at 160° (Will a. Bielschowski, B. 15, 1317). Prisms.

Ethylene derivative $\text{C}_6\text{H}_4\text{NS}_2$, i.e.

$\text{CS} \begin{smallmatrix} \text{N}(\text{C}_6\text{H}_4) \\ \text{S} \end{smallmatrix} \text{C}_6\text{H}_4$. [129°]. Formed by heating

$\text{C}_6\text{H}_4\text{N.C} \begin{smallmatrix} \text{S} \\ \text{NC}_6\text{H}_4 \end{smallmatrix} \text{C}_6\text{H}_4$ with CS_2 at 200°. Yields

$\text{C}_6\text{H}_4\text{NS}_2\text{MeI}$, crystallising in prisms [151°].

***m*-Tolyl-di-thio-carbamic acid**

$\text{C}_6\text{H}_4\text{NH.CS.SH}$.

Salts.— BaA' . Formed from *m*-toluidine, CS_2 , and $\text{Ba}(\text{OH})_2$ in alcohol (Losanitsch, B. 24, 3027). Needles, sol. water, insol. cold alcohol.— NiA' . Yellowish-brown plates.

Methyl ether MeA' . [89°]. Needles.

***p*-Tolyl-di-thio-carbamic acid** $\text{C}_6\text{H}_4\text{NH.CS.SH}$.

Salts.— $\text{NH}_4\text{A'}$. Formed from *p*-toluidine, CS_2 , alcohol, and NH_4Aq (Losanitsch, B. 24, 3026). Yellowish prisms, sol. water, insol. alcohol.— BaA' . Needles.— NiA' . Formed from *p*-toluidine, CS_2 , ammoniacal NiSO_4 , and alcohol. Brown needles, sol. alcohol, insol. water.

Methyl ether MeA' . [84°]. Prisms.

Ethyl ether EtA' . [74°]. Formed by heating $\text{NH}_2\text{C}_6\text{H}_4\text{C}(\text{NC}_6\text{H}_4)\text{SEt}$ with CS_2 at 160° (W. a. B.). Needles, split up by heat into *p*-tolyl thiocarbimide and EtSH .

Ethylene ether $\text{CS} \begin{smallmatrix} \text{N}(\text{C}_6\text{H}_4) \\ \text{S} \end{smallmatrix} \text{C}_6\text{H}_4$.

[126°]. Crystals. Yields a methylo-iodide [107°], which is converted by aniline into $\text{C}_6\text{H}_4\text{N}_4\text{S}$ [128°], and by *o*-toluidine into $\text{C}_{12}\text{H}_{16}\text{N}_4\text{S}$ [82°].

Reference.—NITRO-TOLYL-THIOCARBAMIC ETHER.

***o*-TOLYL-THIOCARBAZIC ACID** *o*-Tolyl hydrazide $\text{C}_6\text{H}_4\text{NH.NH.CS.SNH.NHC}_6\text{H}_4$. Formed from *o*-tolyl-hydrazine, ether, and CS_2 (Preund, B. 24, 4200). Prismatic tables, insol. ether, decomposed by water and alcohol. The *p*-isomeride melts at 109°.

DI-*o*-TOLYL-THIOCARBAZIDE $\text{C}_6\text{H}_4\text{N}_4\text{S}$, i.e. $\text{CS}(\text{NH.NHC}_6\text{H}_4\text{Me})_2$. [130°]. Formed from *o*-tolyl-thiocarbamic acid and *o*-tolyl-hydrazine at 90° (Preund, B. 24, 4201). Needles, sol. alcohol, insol. Aq .

DI-*p*-tolyl-thiocarbazide. [121°]. Formed in like manner at 110° (Preund, B. 24, 4194). Plates, v. sol. hot alcohol.

DI-*o*-tolyl-thiosemicarbazide $\text{C}_6\text{H}_4\text{N}_4\text{S}$, i.e. $\text{NHC}_6\text{H}_4\text{CS.NH.NHC}_6\text{H}_4$. [149°]. Formed by heating *o*-tolyl-thiocarbimide (1 mol.) with *o*-tolyl-hydrazine (1 mol.) in alcohol (Dixon, C. J. 61, 1017). Octahedra, m. sol. hot alcohol, insol. Aq .

DI-*p*-tolyl-thiosemicarbazide. [154°]. Formed in like manner (D.). Prisms, v. e. sol. hot alcohol.

op-Di-tolyl-thiosemicarbaside

[4:1] $C_6H_5Me.NH.CS.NH.NHC_6H_5Me$ [1:2]. [142°]. Formed from *p*-tolyl-thiocarbamide and *o*-tolyl-hydrazine (D.). Prisms, sl. sol. hot alcohol.

Isomeride

[2:1] $C_6H_5Me.NH.CS.NH.NHC_6H_5Me$ [1:4]. [163°]. Formed from *o*-tolyl-thiocarbamide and *p*-tolyl-hydrazine (Dixon, *C. J.* 61, 1015). Prisms, m. sol. hot alcohol.

DI-*o*-TOLYL-THIOCARBAZONE $C_{11}H_{10}N_2S$ *i.e.* $C_6H_5N:N.CS.NH.NHC_6H_5$. [168°]. Formed from di-*o*-tolyl-thiocarbazine and alcoholic potash (Preund, *B.* 24, 4201). Blue-black needles, v. sol. chloroform, sl. sol. alcohol. Conc. H_2SO_4 forms a bluish-green solution.

Di-*p*-tolyl-thiocarbazine. [105°]. Formed in like manner. Dark-blue amorphous flakes.

***o*-TOLYL-THIOCARBIMIDE** $C_6H_5N.S$ *i.e.* [1:2] $C_6H_5Me.N:CS$. (239°). Formed from di-*o*-tolyl-thio-urea by distilling with P_2O_5 (Staats, *B.* 13, 136), by heating with aqueous H_3PO_4 (Hofmann, *B.* 15, 986; Mainzer, *B.* 16, 2017), or by boiling with fuming $HClAq$ (Girard, *B.* 6, 445). Oil.

Reactions.—1. Chlorine forms $C_6H_5.NCl.CSCl$ (218°), which is converted by alcohol into a mixture of di-*o*-tolyl-urea and *o*-tolyl-carbamic ether (Lachmann, *B.* 12, 1349).—2. Chloro-acetic acid and alcohol at 150° form $C_6H_5.N:C<\begin{smallmatrix} S.CH_2 \\ O.CO \end{smallmatrix}$

crystallising in needles [120°], decomposed by boiling baryta-water into *o*-toluidine, CO_2 , and thioglycollic acid (Völtzkoff, *B.* 13, 1580).—3. $PhOMe$ and $AlCl_3$ on warming form $C_6H_5NH.CS.C_6H_5OMe$ [95°] (Tust a. Gattermann, *B.* 25, 3528). $PhOEt$ and $AlCl_3$ give $C_6H_5N.SO$ [116°].

***m*-Tolyl-thiocarbimide** $C_6H_5.N:CS$. (244°) at 732 mm. Formed by boiling di-*m*-tolyl-urea with conc. $HClAq$ (Weith a. Landolt, *B.* 8, 719). Heavy oil. Converted by copper-powder at 220° into *m*-toluic nitrile.

***p*-Tolyl-thiocarbimide** [1:4] $C_6H_5Me.N:CS$. [265°]. (237°). Formed by heating di-*p*-tolyl-thio-urea with P_2O_5 or aqueous H_3PO_4 of S.G. 1.7 (Hofmann, *B.* 1, 173; 15, 986; Staats, *B.* 13, 135). Formed also, together with phenyl-thiocarbimide, by heating $PhN:C:NC_6H_5$ with CS_2 at 190° (Huhn, *B.* 19, 2409). Needles (from ether), v. sol. alcohol.

Reactions.—1. Ammonia forms tolyl-thio-urea, and other bases act in like manner.—2. Bromine forms $C_6H_5.NBr.OSBr$, which readily gives off Br, leaving $(C_6H_5NCS)_2Br_2$ crystallising in plates decomposing at 210° (Helmers, *B.* 20, 790).—2. Chlorine forms $(C_6H_5NCS)_2Cl_2$, whence dilute alcohol gives $(C_6H_5NCS)_2O$ [189°] crystallising in needles.—3. $CH_2Cl.CO_2H$ and alcohol at 150° form $C_6H_5.N:C<\begin{smallmatrix} S.CH_2 \\ O.CO \end{smallmatrix}$ [162°] (Völtzkoff, *B.* 13, 1579).—4. Warmed with toluene and $AlCl_3$ it gives $C_6H_5NH.CS.C_6H_5$ [166°].—5. Heated with $AlCl_3$ it yields $(C_6H_5NCS)_2S$ [176°] (Friedmann a. Gattermann, *B.* 25, 3525).—6. C_6H_5OMe and $AlCl_3$ react, with formation of $C_6H_5NH.CS.C_6H_5OMe$ [157°].—7. C_6H_5OEt and $AlCl_3$ give $C_6H_5.NOS$ [151°], which may be oxidised to $C_6H_5.NOS$ [170°].

DI-*p*-TOLYL DI-THIO-CARBONATE

$CO(SC_6H_5Me)_2$. [91°]. Formed from *p*-tolyl mercaptan and $COCl_2$. It is also a by-product

in the action of *p*-diazo-toluene chloride on potassium xanthate (Leuckart, *J. pr.* [2] 41, 190). Needles (from alcohol).

TRI-TOLYL TRI-THIOCYANURATE

$(C_6H_5Me.SCy)_3$. [114°]. Formed from sodium *p*-tolyl mercaptan and cyanuric chloride (Klason, *J. pr.* [2] 83, 120). Crystals (from $HOAc$).

***o*-TOLYL-THIOHYDANTOIN** $C_6H_5.NSO$ *i.e.* $CS<\begin{smallmatrix} N(C_6H_5Me) \\ NH.CH_2 \end{smallmatrix}>CO$. [136°]. Formed from *o*-tolyl-thiocarbimide and amido-acetic acid (Marckwald, *B.* 24, 3281). Plates, v. sol. alcohol, sl. sol. ligroin.

***p*-Tolyl-thiohydantoïn** [210°] (M.). Formed as above (M.; cf. Aschan, *B.* 17, 426). Flat prisms, sol. alkalis.

Isomeride [183°]. Formed by fusing $CH_2Cl.CO.NHC_6H_5$ with thio-urea (P. Meyer, *B.* 10, 1966). Small crystals.

***p*-Tolyl- ψ -thiohydantoic acid** $C_6H_5N:C(NH_2).S.CH_2.CO_2H$. [176° - 182°]. Formed by boiling chloro-acetic acid with ammonium sulphocyanide, *p*-toluidine, and alcohol (Jäger, *J. pr.* [2] 16, 21). Prisms, not attacked by Ac_2O and Br.

DI-*p*-TOLYL-THIOPHENE $C_{11}H_8S$ *i.e.* $CH:C(C_6H_5Me)>S$. [171°]. Formed by heating di-*p*-tolyl-furfurane with P_2S_5 (Holle-mann, *R. T. C.* 6, 74). Small plates (from alcohol). Gives an intense dark-green colour with isatin and H_2SO_4 .

***o*-TOLYL-THIO-UREA** $NH_2.CS.NHC_6H_5Me$. [155°]. Formed from *o*-tolyl thiocarbimide and NH_3Aq (Staats, *B.* 13, 136). V. sol. hot water and alcohol, sl. sol. ether.

Acetyl derivative $NHAc.CS.NHC_6H_5Me$. [184°]. Formed from acetyl thiocarbimide and *o*-toluidine in alcohol (Dixon, *C. J.* 55, 304). Pale lemon-yellow prisms, insol. water, sol. alcohol.

Benzoyl derivative $NHBz.CS.NHC_6H_5Me$. [119°]. Formed in like manner (Dixon, *C. J.* 55, 623). Pale-yellow prisms, blackened by $AgNO_3$.

Di-*o*-tolyl-thio-urea $CS(NH.C_6H_5Me)_2$. [158°]. Formed from *o*-toluidine and CS_2 (Girard, *B.* 4, 985; Berger, *B.* 12, 1854; Ador a. Rilliet, *B.* 12, 2301). Long needles, v. sol. hot alcohol. Converted by heating with MeI into the hydroiodide of di-tolyl-methyl-thiourea $C_{12}H_{10}N_2S$, which may be represented as 'methyl di-*o*-tolylimido-thiocarbamate' $C_6H_5N:C(SMe).NHC_6H_5$. This body melts at 60°, while the corresponding ethyl derivative melts at 51°. The ethylene derivative [91°] may be represented by the formula $C_6H_5N:C<\begin{smallmatrix} N(C_6H_5) \\ S \end{smallmatrix}>C_6H_5$ (Will a. Bielschowski, *B.* 15, 1316). The isomeric compound [1:2] $C_6H_5Me.N:C<\begin{smallmatrix} N(C_6H_5Me) \\ S \end{smallmatrix}>$ [82°] is got by boiling the methyl-iodide of the ethylene derivative of *p*-tolyl-di-thio-carbamic acid with *o*-toluidine.

***m*-Tolyl-thio-urea** $NHC_6H_5.CS.NH_2$. [103°]. Formed from *m*-tolyl thiocarbimide and ammonia (Weith a. Landolt, *B.* 8, 719). Prisms, m. sol. hot water, v. sol. alcohol and ether.

Di-*m*-tolyl-thio-urea $CS(NHC_6H_5)_2$. [122°]. Formed from *m*-toluidine, CS_2 , and alcohol (W.

a. L.). Needles, v. sol. alcohol, nearly insol. hot water.

p-Tolyl-thio-urea $\text{NHC}_6\text{H}_4\text{CS.NH}_2$. [188°]. (C. a. W.); [182°] (S.). Formed by heating *p*-toluidine hydrochloride with ammonium sulphocyanide (De Clermont a. Wehrin, *C. R.* 83, 347). Formed also from *p*-tolyl-thiocarbimide ammonia (Staats, *B.* 13, 186). Plates (from alcohol) with bitter taste, sl. sol. cold water, m. sol. alcohol.

Acetyl derivative $\text{NHC}_6\text{H}_4\text{CS.NHAc}$. [176°]. Formed from acetyl sulphocyanide and *p*-toluidine (Miguel, *Bl.* [2] 28, 103). Needles, v. e. sol. hot alcohol, v. sol. ether.

Di-p-tolyl-thio-urea $\text{OS(NHC}_6\text{H}_4\text{Me)}_2$. [176°]. Formed by boiling *p*-toluidine with CS_2 and alcohol (Sell, *A.* 126, 160). It is also a product of the action of allyl-thiocarbimide on an alcoholic solution of *p*-toluidine (Maly, *Z.* [2] 5, 258). Trimetric prisms (Levin, *J.* 1882, 884), insol. water, nearly insol. cold alcohol. In alcoholic solution it is converted by HgO into *di-p*-tolyl-urea. In benzene solution COCl_2 forms $\text{C}_{16}\text{H}_{11}\text{N}_2\text{SO}$ [116°] (Will, *B.* 14, 1487). CSCl_2 forms $\text{C}_{16}\text{H}_{11}\text{N}_2\text{S}_2$ [109°] (Freund a. Wolf, *B.* 25, 1465). MeI forms $\text{C}_8\text{H}_7\text{N:C(NHC}_6\text{H}_4\text{)}_2\text{SMe}$ [128°], crystallising in needles, split up by heat into $\text{C(NC}_6\text{H}_4)_2$ [60°] and HSMe , converted by heating with acids or alkalis into *di-o*-tolyl-urea and MeSH , and forming the salts B'HCl [173°] and $\text{B'H}_2\text{SO}_4$ [156°]. EtI forms the corresponding $\text{C}_{11}\text{H}_{20}\text{N}_2\text{S}$ [87°], while ethylene bromide gives $\text{C}_8\text{H}_7\text{N:C(NHC}_6\text{H}_4)_2\text{S}$ [112°], which yields $\text{B'H}_2\text{SO}_4$ [194°] and a hydrochloride [192°] (Will a. Bielschowski, *B.* 14, 1492; 15, 1309).

References.—NITRO- and OXY- TOLYL-THIO-UREA.

p-TOLYL-TOLUTRIAZINE DIHYDRIDE

$\text{C}_{15}\text{H}_{11}\text{N}_3$, *i.e.* CH:CH.C.N.CH_2
 $\text{CMe:CH.C.N.CN.C}_6\text{H}_4\text{Me}$. [178°]. Formed by heating *o*-amido-azo-toluene with formic paraldehyde and alcohol at 140° (Goldschmidt a. Poltzer, *B.* 24, 1008). Prisms, v. sol. hot alcohol.— B'HCl . [220°].— $\text{B}'_2\text{H}_2\text{PtCl}_6$. [216°]. Yellow crystalline pp.

o-TOLYL-URAZOLE $\text{C}_8\text{H}_5\text{N}_2\text{O}_2$ *i.e.*

$\text{C}_8\text{H}_7\text{N}<\begin{smallmatrix} \text{NH.CO} \\ \text{CO.NH} \end{smallmatrix}>$ [170°]. Got by heating *o*-tolyl-hydrazine hydrochloride with urea (Pinner, *B.* 21, 1219). White leaflets, v. sol. hot water.

p-Tolyl-urazole. [274°]. Yellowish needles, v. sl. sol. hot water.

o-TOLYL-UREA $\text{C}_8\text{H}_7\text{N}_2\text{O}$ *i.e.*

$\text{NH}_2\text{.CO.NH.C}_6\text{H}_4\text{Me}$ [1:2]. [185°]. Formed from *o*-toluidine hydrochloride and potassium cyanate (Cosack, *B.* 13, 1089). Plates, sol. alcohol, ether, and hot water.

Benzoyl derivative $\text{CO(NHBz).NHC}_6\text{H}_4$. [210°]. Formed from *o*-tolyl cyanate and benzamide at 125° (Gattermann a. Cantzler, *B.* 25, 1088). Needles.

m-Tolyl-urea $\text{NH}_2\text{.CO.NHC}_6\text{H}_4\text{Me}$ [1:3]. [142°]. Formed from *m*-toluidine hydrochloride and potassium cyanate (Cosack, *B.* 12, 1450; 13, 1089). Needles or tables (from alcohol) or plates (from water).

p-Tolyl-urea $\text{NH}_2\text{.CO.NHC}_6\text{H}_4\text{Me}$ [1:4]. [172°] (C.); [180°] (St.; P.). Formed in like manner (C.; cf. Sell, *C. J.* 16, 190). Formed also by the action of *p*-toluidine on mercuric

fulminate (Steiner, *B.* 8, 519), and also from *p*-toluamidoxim, benzene sulphonic acid, NaOH , and CHCl_3 (Pinnow, *B.* 24, 4167). Needles, sol. hot water, v. sl. sol. ligroin.

Di-o-tolyl-urea $\text{CO(NHC}_6\text{H}_4)_2$. [246°] (B.); [254°] (W.); [256°] (Barr, *B.* 19, 1769).

Formation.—1. By the action of alcohol or water at 100° on the dichloride of *o*-toluic nitrile (Lachmann, *B.* 12, 1849).—2. From *o*-toluidine hydrochloride and cyanamide (Berger, *B.* 12, 1859).—3. From tolyl cyanate and water (Neville a. Winther, *B.* 12, 2325).—4. From *o*-toluidine and COCl_2 (Girard, *B.* 6, 444).—5. By heating *o*-toluidine with urea (G.).—6. A product of the distillation of *o*-tolyl-amido-acetic acid (Widman, *J. pr.* [2] 38, 803).—7. By the action of Ac_2O and benzene on the *o*-toluide of *o*-tolyl-imido-diacetic acid (Bischoff, *B.* 23, 1995).

Properties.—Needles (from HOAc), insol. ether, sl. sol. alcohol. Not volatile with steam.

Di-m-tolyl-urea $\text{CO(NH.C}_6\text{H}_4\text{Me)}_2$. [203°] (G. a. C.); [217°] (C.). Formed from *m*-tolyl cyanate and *m*-toluidine (Gattermann a. Cantzler, 25, 1089), by the action of ClCO.Et on *m*-toluidine, by heating *m*-tolyl-carbamic ether with water, and by heating *m*-tolyl-urea with *m*-toluidine at 160° (Cosack, *B.* 12, 1450; 13, 1090). Needles (from alcohol), insol. water.

Di-p-tolyl-urea $\text{CO(NH.C}_6\text{H}_4\text{Me)}_2$. [255°].

Formation.—1. By boiling an alcoholic solution of *di-p*-tolyl-thio-urea with HgO as long as HgS is formed (Sell, *C. J.* 16, 190; *A.* 126, 161).—2. By passing COCl_2 into *p*-toluidine dissolved in chloroform (Miehler, *B.* 9, 710; Kühn, a. Henschel, *B.* 21, 505).—3. By heating tolyl-urea with *p*-toluidine at 160° (Weith, *B.* 9, 821).—4. From *p*-tolyl-cyanate and *p*-toluidine (Gattermann a. Cantzler, *B.* 25, 1089).

Properties.—Needles, insol. water, sl. sol. cold alcohol.

Tri-p-tolyl-urea $\text{C}_{22}\text{H}_{22}\text{N}_3\text{O}$. [189°]. Got from $\text{(C}_6\text{H}_4)_2\text{N.COCl}$ and *p*-toluidine (Hammerich, *B.* 25, 1822). Needles, sol. warm benzene, insol. ether. Gives a benzoyl derivative [187°].

Tetra-p-tolyl-urea $\text{C}_{26}\text{H}_{26}\text{N}_4\text{O}$. [80°]. Got from $\text{(C}_6\text{H}_4)_2\text{N.COCl}$ and *di-p*-tolyl-amine. Needles, v. e. sol. alcohol.

References.—AMIDO-, NITRO-, and OXY-TOLYL-UREA.

TOLYL-XYLIDINE $\text{C}_{15}\text{H}_{11}\text{N}$ *i.e.*

$\text{C}_6\text{H}_4\text{Me.NH.C}_6\text{H}_4\text{Me}_2$. [70°]. (c. 300° at 487 mm.). Silky needles (from alcohol) (Girard a. Vogt, *Bl.* [2] 18, 69).

o-TOLYL-*m*-XYLYL KETONE $\text{C}_{15}\text{H}_{11}\text{O}$ *i.e.* [1:2] $\text{C}_6\text{H}_4\text{Me.CO.C}_6\text{H}_4\text{Me}_2$ [1:2:3]. (380°) at 728 mm. Formed from *o*-toluic chloride and *m*-xylene (Smith, *B.* 24, 4050). Oil. Converted by hydroxylamine at 120° into a mixture of anilides.

TONKA BEANS, the fruit of *Dipteris odorata*, contains coumarin (*g. v.*) (Boullay a. Boudron-Charlard, *J. Ph.* 11, 426; [3] 7, 160).

TRAGACANTH GUM. Exudes from *Astragalus verus*, a tree growing in Armenia and the north of Persia. It swells up in water, about one-half of it dissolving. It contains arabin, bassorin, starch, and water.

TRANSPIRATION. Graham, in 1846 and 1849, applied the term 'transpiration' to the passage of gases through capillary tubes into a

vacuum (*v. T.* 1846. 573; 1849. 849). The rates of transpiration of different gases bear constant relations to each other; but these rates have not been connected in any definite ways with the compositions of the gases. M. M. P. M.

TREE GUM *v. XYLAN*.

TREHALOSE *v. SUGAR*.

TREHALUM $C_{24}H_{42}O_{21}$. S. $\cdot 06$ at 17° ; $1\cdot 8$ at 100° . $[\alpha]_D = +179^\circ$. Occurs in *Trehala manna* (Scheibler & Mittelmeier, *B.* 26, 1331). Tasteless, minute prisms. Very hygroscopic. Does not reduce Fehling's solution. Does not react with phenyl-hydrazine. Boiling dilute H_2SO_4 forms glucose. At 180° it slowly forms trehalin, which is *v. sol.* water and *ppd.* by alcohol. Trehalin dissolves in phenyl-hydrazine. Iodine colours trehalum and trehalin violet. Diastase, yeast, and invertin have no action. Ac_2O and $NaOAc$ yield an acetyl derivative [above 240°].

TRI- In the alphabetical arrangement of this dictionary the prefix 'tri,' when indicating the presence of three radicles, is treated as if it did not form part of a name, except where the entire name is numerical, as in 'tridecane.'

TRIANOSPERMIN. A crystalline substance occurring in *Trianosperma ficifolia*, a climbing plant of Brazil (Peckholt, *Ar. Ph.* [2] 113, 104; Parodi, *Ph.* [3] 10, 667). It has a pungent taste, is alkaline in reaction, *sol.* water, alcohol, and ether, and is *ppd.* by $Pb(OAc)_2$ and $PtCl_4$.

TRIAZOLE $N \begin{smallmatrix} \text{CH:N} \\ \text{CH.NH} \end{smallmatrix}$. *Pyrroldiazole*. [$120\cdot 5^\circ$]. (260°). V.D. 2.39 (calc. 2.49). Formed by heating its carboxylic acid alone or with boiling water (Andreocci, *B.* 25, 229; Bladin, *B.* 25, 745). Needles (from ether), *v. sol.* water and alcohol, may be sublimed. The di-oxy-derivatives of alkyl-triazoles $N \begin{smallmatrix} \text{C(OH):N} \\ \text{C(OH).NR} \end{smallmatrix}$, named by Pinner 'urazoles,' are obtained by heating hydrazines with urea (Pinner, *B.* 20, 2358).

TRIAZOLE CARBOXYLIC ACID

$N \begin{smallmatrix} \text{CH} \text{---} \text{N} \\ \text{C(CO}_2\text{H).NH} \end{smallmatrix}$ [137°]. Obtained by oxidising methyl-triazole (Andreocci, *B.* 25, 229) or amido-phenyl-triazole carboxylic acid and alkaline $KMnO_4$ (Bladin, *B.* 25, 744). Amorphous powder.— CuA' , aq. Green crystalline powder.

TRICARBALLYLIC ACID *v. vol. i.* p. 679.

TRICOSANE *v. TRI-ICOSANE*.

TRIDECANE $C_{13}H_{28}$. [-6°]. (234°). S.G. $\frac{4}{5}$ 771; $\frac{5}{4}$ 761. Formed by reduction of methyl dodecyl ketone or of tridecoic acid by HI and P (Krafft, *B.* 15, 1699). Formed also by distilling barium myristate with $NaOMe$ (Mai, *B.* 22, 2134).

TRIDECOIC ACID $C_{12}H_{25}.CO_2H$. [41°]. (236° at 100 mm.). Formed by oxidation of methyl tridecyl ketone (Krafft, *B.* 12, 1669). Crystals.— AgA' .

Amide $C_{12}H_{25}.CO.NH_2$. [$98\cdot 5^\circ$]. Formed by digesting the nitrile with conc. H_2SO_4 and pouring into water (Lutz, *B.* 19, 1439). Plates (from alcohol).

Nitrile $C_{12}H_{23}.CN$. (275°). Formed from tridecylamine; Br_2 and $NaOH$. Oil, *v. sol.* alcohol and ether.

TRIDECYL ALCOHOL ($C_{13}H_{27}$). CH_2OH . [42°]. Formed by reducing di-hexyl ketone (Kipping, *C. J.* 57, 536). Plates (from dilute alcohol),

insol. water. May be distilled. HBr forms ($C_{13}H_{27}$). $CHBr$ [39°].

TRIDECYLAMINE $C_{13}H_{27}.NH_2$. [37°]. (265°). Formed by boiling myristyl-tridecyl-urea with $KOHAq$ (Lutz, *B.* 19, 1437). Unctuous mass, *v. sol.* alcohol and ether. Absorbs water and CO_2 from the air.— $B'HCl$: needles, decomposing at 100° .— $B'_2H_2PtCl_6$.— $B'_2H_2SO_4$: needles, *insol.* cold water.

TRIDECYLENE $C_{13}H_{26}$. (233° cor.). S.G. $\frac{2}{4}$ 8445. Occurs in petroleum from Burmah (Warren & Storer, *Z.* 1868, 232).

TRIDECYL-UREA. *Myristyl derivative* $C_{13}H_{27}.N_2O_3$, *i.e.* $C_{13}H_{27}.NH.CO.NHC.H_2O$. [103°]. Formed by the action of Br and $KOHAq$ on the amide of myristic acid (Reimer & Will, *B.* 18, 2016). Crystals (from alcohol), almost *insol.* cold water, *sol.* ether.

TRIGENIC ACID *v. ETHYLIDENE-BIURET*.

TRIGONELLIN $C_8H_9NO_3$, *i.e.*

$CH \begin{smallmatrix} \text{CH} \text{---} \text{O} \text{---} \text{CO} \\ \text{CH:NMe} \text{---} \text{O} \end{smallmatrix}$. Occurs in the seeds of

Trigonella Fenum-graecum (Jahns, *B.* 18, 2518; 20, 2840). It is also produced by saponification of the product of the reaction of MeI on potassium pyridine (β)-carboxylate (Hantzsch, *B.* 19, 31). Colourless prisms (containing aq), converted by $HClAq$ at 265° into pyridine (β)-carboxylic acid (*q. v.*, Reaction 4).— $B'HCl$.— $B'_2H_2PtCl_6$.— $B'HAuCl_4$ [198°].— B'_2HAuCl_4 [186°]. Slender needles.

n-TRI-ICOSANE $C_{23}H_{48}$. [48°]. (234° at 15 mm.). S.G. $\frac{4}{5}$ 7785; $\frac{5}{4}$ 7570. Formed from laurone ($C_{11}H_{23}$). CO by treatment with PCl_5 and reduction of the resulting ($C_{11}H_{23}$). CCl_2 with HI and P at 240° (Krafft, *B.* 15, 1712). Obtained also by fractional distillation of paraffin oil from brown coal (Krafft, *B.* 21, 2263). Glittering plates (from ether-alcohol), *sl. sol.* alcohol.

TRI-ICOSANE DICARBOXYLIC ACID

$C_{22}H_{44}(CO_2H)_2$. [$102\cdot 5^\circ$]. Formed by heating di-oxy-penta-icosylene with soda-lime (Stärke, *A.* 223, 300). Flocculent pp. (from ligroin-ether).— PbA' .

TRI-ICOSYL ALCOHOL ($C_{11}H_{23}$). CH_2OH .

[76°]. Formed by reducing laurone with Na and water (Kipping, *C. J.* 57, 983). Plates (from ether), *insol.* water. Yields an acetyl derivative ($C_{11}H_{23}$). CH_2OH [35°].

TRI-ICOSYL ALCOHOL $C_{22}H_{44}.OH$. [82°]. A wax-like body extracted by hot alcohol from flax fibres (Cross & Bevan, *C. N.* 69, 135). Yields an acetyl derivative [65°].

TRIMELLITIC ACID *v. vol. iii.* p. 201.

TRIMESIC ACID *v. vol. iii.* p. 230.

TRIMESITIC ACID *v. PYRIDINE TRICARBOXYLIC ACID*.

TRIMETHYLENE *v. vol. iii.* p. 304.

TRITICIN $C_{12}H_{22}O_{11}$. [$a_D = -43\cdot 6^\circ$ (Reide-meister, *J. Th.* 1881, 69). Extracted by dilute alcohol from the root of couch-grass (*Triticum repens*) (H. Müller, *Ar. Ph.* [3] 2, 500; 3, 1). Tasteless hygroscopic powder, *v. sol.* water, *insol.* alcohol and ether. Lævorotatory. On boiling with water, especially in presence of acids, it changes into lævulose. Its solutions are not *ppd.* by metallic salts, nor coloured by iodine.

TROPEOLINES *v. Azo-compounds*.

TROPEINES. A name given by Ladenburg to alkyl derivatives of tropine (*q. v.*).

TROPIC ACID *v.* OXY-PHENYL-PROPIONIC ACID.**TROPIDINE** *v.* METHYL-ETHYLENE PYRIDINE TETRAHYDRIDE.

(*a*). Methyl-tropidine $C_9H_{11}N$ *i.e.*
 $CH_3 \cdot CH \cdot CH \cdot CH \cdot CH \cdot CH \cdot CH \cdot NMe_2$ (Ladenburg)
 or $CH \begin{smallmatrix} CH \cdot CH \\ CH \cdot CH \end{smallmatrix} > CH \cdot CH \cdot NMe_2$ (Merling).

Formed by distilling tropidine methylo-hydroxide with water (Roth, *B.* 17, 157; Merling, *B.* 24, 8118). Oil. HClAq forms 'hydrochloro-(*a*)-methyl-tropidine' which gradually changes into the isomeric tropidine methylo-chloride. — $B_2H_2PtCl_6$. [174°]. — $B'HAuCl_4$: golden-yellow pp. *Methylo-iodide* $B'MeI$. [162°]. Needles.

(*β*). Methyl-tropidine $C_9H_{11}N$. (205°). S.G. 1.922. Formed by heating (*a*)-methyl-tropidine at 150°–200°. Oil. Converted by HCl into tropilene.

TROPIGENIN $C_9H_{11}NO$. [161°]. Got by oxidation of tropine by alkaline $KMnO_4$ (Merling, *B.* 15, 287). Got also by boiling 'homohydro-apotropine' with baryta-water (Pesci, *G.* 12, 329). Needles, sol. water and alcohol. Reconverted by MeI into tropine. Oxidised by chromic acid mixture to ecgonic acid and a small quantity of tropic acid (Liebermann, *B.* 24, 615). — $B'HI$. — $B'CO_2$: crystalline pp. — $B'_2H_2PtCl_6$ aq. — $B'HAuCl_4$: golden-yellow plates, sol. alcohol.

TROPILENE C_9H_{10} *i.e.*

$CH \begin{smallmatrix} CH \cdot CH \\ CH \cdot CH \end{smallmatrix} > CH \cdot CHO$ (?) (Merling) (182°) (*L.*); (187°) (*M.*). S.G. 1.0091. V.D. 102.3 (calc. 110). Formed by distilling tropidine methylo-iodide with KOH (Ladenburg, *B.* 14, 2403; 15, 1028; *A.* 217, 138). Formed also from (*β*)-methyl-tropidine and cold HClAq (Merling, *B.* 24, 8123). Oil, smelling like oil of bitter almonds and acetone, sol. dilute HClAq, *v.* sol. alcohol and ether. Reduces warm ammoniacal $AgNO_3$, forming a mirror. Reduces Fehling's solution and $KMnO_4$ in the cold. Not attacked by $AcCl$. Combines with $NaHSO_4$ (*M.*). Nitric acid forms an adipic acid $C_9H_{10}O_4$. Slowly combines with methylamine, forming (*β*)-methyl-tropine.

TROPILIDENE C_9H_8 *i.e.*

$CH \begin{smallmatrix} CH \cdot CH \\ CH \cdot CH \end{smallmatrix} > C \cdot CH_2$. (114°). S.G. 0.9129.

Formed by distilling methyl-tropine methylo-iodide with KOH (Ladenburg, *A.* 217, 133; *B.* 14, 2403; 26, 1067). Formed also, together with methylamine, by distilling tropine with soda-lime. Oil, smelling somewhat like toluene, but combining readily with bromine, forming $C_9H_8Br_2$. Gives no pp. with ammoniacal $CuCl_2$. Oxidised by CrO_3 to benzoic aldehyde and acid (Merling, *B.* 24, 8122).

TROPINE C_9H_9NO *i.e.*

$CH \cdot CH_2 \cdot CH \cdot CH_2 \cdot CH_2 \cdot OH$ (Ladenburg) or $CH \cdot CH_2 \cdot NMe$

$CH \cdot CH \begin{smallmatrix} CH \cdot CH \\ CH \cdot CH \end{smallmatrix} > CH_2 \cdot OH$ (Merling). *Methyl-oxy-*

ethyl-pyridine tetrahydride. [62°] (229°). Formed, together with tropic acid, by hydrolysis of atropine or hyoscyamine by baryta or HClAq (Kraut, *A.* 128, 281; 183, 87; Ladenburg, *A.* 206, 292; 217, 115; *B.* 18, 608; 20, 1653; 23, 1780; 26, 1067). Hygroscopic tables (from ether), *v.* *s.* sol. water and alcohol. Does not absorb CO_2 from the air. Its aqueous solu-

tion ppts. metallic oxides from their salts. Not attacked by nitrous acid. Not volatile with steam. According to Eykman (*B.* 26, 1400) the refractive index agrees best with Merling's formula.

Reactions.—1. Decomposed by distilling with soda-lime into tropilidene, methylamine, and H_2O .—2. Loses H_2O , being converted into tropidine by heating with fuming HCl and $HOAc$ at 180° or by heating with H_2SO_4 (1 pt.) and water (1½ pts.) at 230°.—3. Conc. HIAq and red P at 150° form tropidine and tropidine periodide, but at 140° they form 'tropine iodide' $C_9H_{11}NI_2$, which crystallises from water in prisms [115°], whence silver chloride followed by $PtCl_4$ give $(C_9H_{11}NI_2)PtCl_4$, crystallising in red octahedra. By treatment with Ag_2O followed by HCl and $PtCl_4$, very soluble $(C_9H_{11}NCl_2)PtCl_4$ is got.—4. Alkaline $KMnO_4$ forms tropigenin anu., finally, oxalic acid and NH_3 (Merling, *A.* 216, 341).—5. CrO_3 forms tropinic acid $C_9H_{11}N(CO_2H)_2$.—6. Aqueous $HOCl$ yields prisms [111°], whence alcohol produces $C_9H_{11}NCl_4 \cdot CH_3OH$ [108°], which forms a hydrochloride [162°] crystallising in plates (Einhorn & Fischer, *B.* 25, 1391).

Salts. — $B'HCl$. — $B'_2H_2PtCl_6$. Orange-red monoclinic crystals. [200°] (Schmidt, *A.* 208, 214). — $B'HAuCl_4$. [212°]. — $B'HCl_6HgCl_2$. [246°] (Ladenburg, *B.* 24, 1631). — $B'_2C_9H_9N_2O_7$.

Nitroxy derivative $C_9H_{11}(ONO_2)N$. *Nitro-tropine*. Formed by warming tropine (2 g.) with HNO_3 (12 g. of S.G. 1.25) at 100° (Ladenburg, *B.* 15, 1025). Alkaline liquid, sol. water, alcohol, and ether. Yields KNO_3 on boiling with KOH . — $B'_2H_2PtCl_6$. Needles. — $B'HI$. Prisms.

Benzoyl derivative $C_9H_{11}(OBz)N$. *Benzoyl-tropine*. Formed by heating tropine hydrochloride with benzoic acid and dilute HCl (Ladenburg, *B.* 13, 1083; *A.* 217, 96). Crystallises as $C_9H_{11}NO_2 \cdot 2aq$ [58°], $C_9H_{11}NO_2 \cdot aq$ [37°], or anhydrous [42°]. Sl. sol. water, *v.* sol. alcohol and ether. — $B'HNO_3$. — $B'_2H_2PtCl_6 \cdot 2aq$. — $B'_2C_9H_9N_2O_7$.

o-Oxy-benzoyl derivative $C_9H_{11}(O.CO.C_6H_4.OH)N$.

Salicyl-tropine. Formed in like manner, using salicylic acid (Gaebe & Caro, *B.* 13, 106; *L.*). Silky plates. Feeble poison, 0.25 g. killing a frog in a few hours. Has no apparent effect on the pupil. — $B'HCl$. — $B'_2H_2PtCl_6$. — $B'HAuCl_4$: yellow plates.

m-Oxy-benzoyl derivative $C_9H_{11}NO_2$. [226°]. Small plates, *v.* sl. sol. water. Acts slightly on the pupil of the eye. — $B'HCl$. — $B'_2H_2SO_4 \cdot 4aq$. — $B'_2H_2PtCl_6$: orange plates.

p-Oxy-benzoyl derivative $C_9H_{11}NO_2$. [227°]. Trimetric plates (containing 2aq). — $B'HNO_3$. — $B'_2H_2PtCl_6 \cdot 2aq$. Orange plates.

Phenyl-acetyl derivative $C_9H_{11}NO_2$ *i.e.* $C_9H_{11}N(O.CO.CH_2Ph)$. *Phenylacetotropine*. Aromatic oil. — $B'HBr$. — $B'_2H_2PtCl_6$. — $B'HAuCl_4$. — $B'_2H_2SO_4$. Soluble tables.

Mandelyl derivative $C_9H_{11}NO_2$ *i.e.* $C_9H_{11}N(O.CO.CHPh.OH)$. *Homatropine*. Formed by heating tropine with mandelic acid, HCl (1 pt.), and water (40 pts.), the yield being 50 p.c. of the theoretical amount (Ladenburg, *C. R.* 90, 921; *A.* 217, 82). Deliquescent prisms (from ether), sl. sol. water. A solution of its hydrochloride is ppd. by potassio-mercuric iodide, but not by tannin. It enlarges the pupil of the eye almost as energetically as atropine, but the enlargement passes off much more rapidly (Völkers,

A. 217, 86; Bertheau, *Berl. Klin. Wochenschrift*, 1880, No. 41; Tweedy & Ringer, *Lancet*, 1880, No. 21).—B'HBr. Trimetric crystals; $a:b:c = 414:1:472$.— $B_2O_3.H_2N_2O_7$. Yellow plates.— $B'HAuCl_4$.— $B_2H_2SO_4$. Needles.

Cinnamoyl derivative $C_{11}H_{11}NO_7$. [70°]. Small plates (from dilute alcohol). Gives pps. with tannin, picric acid, potassio-mercuric iodide, and I in KI. Strong poison, .03 g. killing a frog in three minutes. Has little action on the pupil.— $B'HCl$.— $B_2H_2PtCl_4$.— $B'HAuCl_4$. Needles.

Atropyl derivative $C_{11}H_{11}NO_7$. **Atrop-tropine**. Oil.— $B'HAuCl_4$. Small needles.

Atrolactyl derivative $C_{11}H_{11}NO_7$. **Pseudo-atropine**. [120°]. Formed from atrolactic acid, tropine, and dilute HCl (1:400) by repeated evaporation (Ladenburg, A. 217, 87). Needles (from water). Resembles atropine in physiological action, two drops of a 1 p.c. solution expanding the pupil and paralyzing accommodation for a week.— $B'HAuCl_4$. [114°].

Phthalyl derivative $C_{12}H_{12}N_2O_7$. [70°]. Formed, in very small quantity, by evaporating phthalic acid with tropine and dilute HCl. Mass of silky needles.— $B'H_2PtCl_4$.

Methylo-iodide $C_8H_9NO.MeI$. Small crystals, nearly insol. alcohol. Yields $B'MeOH$ and $B_2Me_2PtCl_4$ (Merling, B. 14, 1829; Ladenburg, A. 217, 131).

Ethyl-iodide $B'EtI$. Crystalline. Yields $B_2Et_2PtCl_4$, a yellow crystalline powder.

(a)-Methyl-tropine C_8H_9MeNO . (243°). Formed by distilling tropine methylo-iodide. Liquid, v. sol. water and alcohol. Strongly alkaline. Its hydrochloride, distilled with solid KOH, yields dimethylamine.— $B'HAuCl_4$. Very unstable.

Methylo-iodide (C_8H_9MeNO) MeI . Deliquescent needles, decomposed by distilling with solid KOH into tropilidene and trimethylamine.— $(C_8H_9MeNO)_2Me_2PtCl_4$. Orange crystals.

(b)-Methyl-tropine C_8H_9NO . (198°–205°). Formed by shaking tropilene with an aqueous solution of dimethylamine (Ladenburg, B. 14, 2404). Liquid, split up by gaseous HCl into tropilene and NMe_2H .— $B'HAuCl_4$. Prisms.

(γ)-Methyl-tropine C_8H_9NO . Formed in small quantity by distilling the methylo-hydroxide of (a)-methyl-tropine (Merling, B. 15, 288). V. sl. sol. Aq.— $B_2H_2PtCl_4$. V. sl. sol. Aq.

Metatropine C_8H_9NO . (238°). Formed by shaking tropine iodide with water and Ag_2O . Not solid at -80° .— $B'HCl$: tables.

Hydrotropidine C_8H_9N . (168°). S.G. 2.937; 15.926. Formed by reducing tropine iodide $C_8H_9NI_2$ with zinc-dust and HClAq (Ladenburg, B. 16, 1408). Liquid, m. sol. water.— $B'HCl$: deliquescent crystals.— $B_2H_2PtCl_4$. Tables.

Norhydrotropidine C_8H_9N . [60°]. (161°). Formed by distilling hydrotropidine hydrochloride in a current of HCl (Ladenburg, B. 20, 1649). Crystalline.— $B'HCl$. [281°].— $B_2H_2PtCl_4$.— $B'HHgCl_2$.— $B_2C_2H_2N_2O_7$. Needles.

Nitrosamine $C_8H_9N_2O$. [117°]. Cubes.

Paratropine C_8H_9NO . (202°). Formed from hydrotropine and K_2FeCy , (Ladenburg, B. 24, 1626).— $B_2H_2PtCl_4$. [197°].— $B'HAuCl_4$. [182°].— $B'HCl_6HgCl_2$. [225°]. V. sol. water.

ψ-Tropine C_8H_9NO . [108°]. (242°). Formed, together with tropic acid, by warming hyoscyne with baryta-water (Ladenburg, B. 18, 1551; 17,

151; Liebermann, 24, 2587). Formed also by dissolving its benzoyl derivative in hot conc. HClAq (Hesse, A. 271, 210). Hygroscopic prisms (from chloroform), v. s. sol. water. Yields tropine and eegonic acids on oxidation.— $B_2H_2SO_4$. Hygroscopic crystals.— $B'HAuCl_4$. [198°] (Ladenburg); [202°] (H.); [225°] (Liebermann).— $B_2H_2PtCl_4$ 4aq. [206°, anhydrous]. Trimetric prisms; $a:b:c = 702:1:879$.

Methylo-iodide $B'MeI$. [270°]. Rhombohedra. Yields $B'MeCl$ and $B_2Me_2PtCl_4$. [216°] crystallising from water.

Benzoyl derivative $C_{15}H_{15}NO_7$. [48°]. Occurs in the leaves of Java coca (Liebermann, B. 24, 2336; Hesse, A. 271, 208). Colourless plates (from ether).— $B'HCl$. [270°].— $B_2H_2PtCl_4$. Pale-yellow needles.— $B'MeI$.— $B'MeCl$.— $B_2Me_2PtCl_4$ 2aq.

Mandetyl derivative $C_8H_9NO(CO.CH(OH).C_6H_5)$. **ψ-Homatropine**. Formed by heating ψ-tropine with mandelic anhydride at 200° (Liebermann & Limpach, B. 25, 931).— $B'HCl$.— $B_2H_2PtCl_4$.— $B'HAuCl_4$.

Tropyl derivative $C_8H_9NO(C_6H_5O)$. Isomeride of hyoscyne. [88°]. $[α]_D = -4.9^\circ$. Nodules, insol. water, sol. alcohol.— $B'HCl$. [183°].— $B_2H_2PtCl_4$.— $B'HAuCl_4$. [135°].

Atropyl derivative. [129°]. Formed from tropide and ψ-tropine at 200°. Crystals, sol. water. Split up by HClAq into atropic acid and ψ-tropine.

Oxy-tropine carboxylic acid
 $CH_2.CH_2.CH(OH).CH(OH).CO_2H$. **Dioxyan-CH.CH_2.NMe**

hydroecgonine. Formed by oxidising hydroecgonine with $KMnO_4$ and aqueous Na_2CO_3 at 1° (Einhorn & Rassoff, B. 25, 1395). Decomposes at 280°. V. s. sol. water and $MeOH$, insol. $EtOH$.— $B'HCl$. [251°].— $B_2C_2H_2N_2O_7$.— KA' .

Methyl ether MeA' . [139°]. Tables, v. s. sol. $CHCl_3$. Yields $B_2H_2PtCl_4$. [210°].

Benzoyl derivative of the methyl ether $C_8H_9MeN.CH(OH).CH(OBz).CO_2H$. [108°]. Needles.— $B'HNO_3$. [216°].— $B'HCl$. [203°].— $B'HAuCl_4$. [173°].— $B_2H_2PtCl_4$. [208°].

Di-benzoyl derivative of the methyl ether $C_8H_9MeN.CH(OBz).CH(OBz).CO_2H$. Needles.— $B'HNO_3$. [190°].— $B'HCl$. [280°].— $B_2H_2PtCl_4$. [205°].— $B'HAuCl_4$. [208°].

Reference.—OXYTROPINE.

TROPINE DIHYDRIDE C_8H_9NO i.e.
 $CH_2.CH_2.CH(OH).CH_2.CH_2OH$. **Hydrotropine.**
 $CH_2.CH_2.NMe$

Methyloxyethylpyridine hexahydrate. (233°). Formed from oxy-ethyl-piperidine and $KMeSO_4$ (Ladenburg, B. 24, 1622). V. sol. water and alcohol.— $B'HCl_5HgCl_2$. [214°].— $B'HAuCl_4$. [170°]. Crystals.

TROPINIC ACID $C_8H_9NO_7$. [253°] (L.); [220°] (M.). A product of oxidation of tropine and of ecgonine by chromic acid mixture (Merling, A. 216, 348; Liebermann, B. 28, 2519). Needles, v. sol. water, al. sol. alcohol, insol. benzene. Gives off CO_2 when heated. Forms salts with acids and bases.— BAA' . Very hygroscopic.— CaA' .— AgA' . Readily reduced.— $(HA')_2PtCl_4$.— $HA'HAuCl_4$. Golden prisms.— $HA'HCl$ aq.

TROPYLENE v. **TROPILENE**.

TRUXENE (C_8H_8). Formed by heating truxone with red P and HIAq (S.G. 1.7) at 180°

(Liebermann a. Bergami, *B.* 22, 786; 23, 817). Formed also by heating hydrindone with conc. HClAq , and by heating phenyl-propionic acid with P_2O_5 (Hausmann; Kipping, *O. J.* 65, 269). Needles or plates, melting above 860° , insol. CHCl_3 . Oxidised by boiling HOAc and CrO_3 to crystalline 'tri-benzoylene-benzene,' which is not melted at 860° . HNO_3 forms (4,2,1)-nitro-phthalic acid.

(a)-TRUXILLIC ACID $\text{C}_{15}\text{H}_{10}\text{O}_4$ *is.*

$\text{CHPh.CH.CO}_2\text{H}$ (?) (γ)-Isotropic acid.
 $\text{CO}_2\text{H.CH—CHPh}$

[274°]. Formed, together with (β)-truxillic acid, by the action of boiling HClAq on isotropylcocaine, which is a by-product in the preparation of cocaine (Liebermann, *B.* 21, 2342; 22, 124, 783, 2242). Small needles (from alcohol), sol. hot HOAc . Yields cinnamic acid on distillation. Nitric acid (S.G. 1.52) forms two di-nitro-derivatives, [229°] and [290°]. Yields two isomeric sulphonic acids.— $\text{Na}_2\text{A}''$ 10aq (Drory, *B.* 22, 2256).— BaA'' 8½aq. Crystalline, v. sol. water.— CaA'' aq.— $\text{Ag}_2\text{A}''$. Flocculent pp., sol. NH_4Aq .

Methyl ether $\text{Me}_2\text{A}''$. [174°]. (c. 300°).

Ethyl ether $\text{Et}_2\text{A}''$. [146°]. H.C.p. 2,720,990 (Liebermann, *B.* 25, 92). Yields $\text{C}_{15}\text{H}_{12}(\text{NO}_2)_2\text{Et}_2\text{O}_4$ [138°] (Homans, *B.* 24, 2590).

Isoamyl ether $(\text{C}_5\text{H}_{11})_2\text{A}''$. [83°]. Prisms. Ac_2O at 160° forms (α)-truxillic anhydride, while at 170° the product is (γ)-truxillic anhydride.

Di-amide $\text{C}_{15}\text{H}_{10}\text{O}_2(\text{NH}_2)_2$. [265°]. Needles, v. sl. sol. hot water, sl. sol. alcohol (Drory, *B.* 22, 2261).

Di-piperidine $\text{C}_{15}\text{H}_{14}(\text{CO.NC}_5\text{H}_{10})_2$. [259°]. Got from the chloride and piperidine (Herstein, *B.* 22, 2264). Crystalline powder, sol. alcohol.

Mono-piperidine

$\text{C}_{15}\text{H}_{14}(\text{CO}_2\text{H})(\text{CO.NC}_5\text{H}_{10})$. [250°]. Yields MeA' [151°] crystallising from ether in needles.

Anhydride $(\text{C}_{15}\text{H}_{10}\text{O}_4)_n$. [191°]. Mol. w. 1712 (1703 obs. by Raoult's method). Formed by heating the acid with Ac_2O and NaOAc at 100° . Needles (from benzene-ligroin). Gives no fluorescein. When heated for an hour at 200° it changes to (γ)-truxillic anhydride.

(β)-Truxillic acid $\text{C}_{15}\text{H}_{10}\text{O}_4$ *is.*

$\text{CHPh.CH.CO}_2\text{H}$ (?)
 $\text{CHPh.CH.C'O}_2\text{H}$ (?)

(β)-Isotropic acid. [206°]. Formed at the same time as the (α)-acid (Liebermann, *B.* 21, 2342; 22, 783, 2243; 25, 90; 26, 837). More sol. water than the (α)-isomeride. Yields benzil on oxidation. Nitric acid (S.G. 1.52) forms a di-nitro-derivative [216°] (Homans, *B.* 24, 2590). Forms cinnamic acid on distillation.— $\text{Na}_2\text{A}''$ 2aq.— BaA'' 2aq. Sl. sol. water.— CaA'' 3aq.— $\text{Ag}_2\text{A}''$.

Methyl ether $\text{Me}_2\text{A}''$. [76°]. Mol. w. 309 (by Raoult's method; calc. 324. H.C.p. 2,422,900. Monoclinic prisms; $a:b:c = 826:1:2.019$; $\beta = 89^\circ 22'$.

Ethyl ether $\text{Et}_2\text{A}''$. [47°].

Chloride $\text{C}_{15}\text{H}_{10}\text{O}_4\text{Cl}_2$. [96°]. Tabular prisms, v. sol. ether (Drory, *B.* 22, 2260).

Monopiperidine $\text{C}_{15}\text{H}_{14}(\text{CO}_2\text{H})(\text{CONC}_5\text{H}_{10})$. [224°]. Formed from (β)-truxillic anhydride and piperidine (Herstein, *B.* 22, 2264). Needles, sl. sol. cold alcohol.

Dipiperidine $\text{C}_{15}\text{H}_{14}(\text{CO.NC}_5\text{H}_{10})_2$. [180°]. Formed from the chloride and piperidine. Prisms, v. sol. alcohol.

Phenylimide $\text{C}_{15}\text{H}_{11}\langle\text{CO}\rangle\text{NPh}$. [180°].

Mol. w. 351 (obs.). Got by heating the anhydride with aniline. Colourless needles (from alcohol). Cold alcoholic potash forms the compound $\text{CO}_2\text{H.C}_{15}\text{H}_{11}\text{CO.NHPh}$ [197°].

Phenyl hydrazide $\text{C}_{15}\text{H}_{11}\langle\text{CO.NH}\rangle\text{CO.NHPh}$ [218°]. Formed from the acid, phenyl-hydrazine, and HOAc on warming. Crystals (from HOAc).

Fluorescein $\text{C}_{15}\text{H}_{11}\langle\text{C}(\text{C}_6\text{H}_4(\text{OH})_2)_2\rangle\text{O}$.

Formed by heating the acid or its anhydride with resorcin at 240° . Amorphous brownish-red powder, sol. alkalis forming fluorescent solutions, v. sol. alcohol, insol. benzene.

Anhydride $\text{C}_{15}\text{H}_{10}\text{O}_4$. [116°]. Mol. w. 278 calc., 289 obs. by Raoult's method. Does not change to an isomeride when heated.

(γ)-Truxillic acid $\text{C}_{15}\text{H}_{10}\text{O}_4$. ϵ -Isotropic acid. [228°]. Formed by heating the anhydride of the (α)-isomeride with HCl at 160° . Needles (from dilute alcohol), v. sl. sol. hot water, v. sol. ether. Yields cinnamic acid on distillation. Gives the same anhydride as the (α)-isomeride (Ladenburg, *B.* 22, 124). Heated with HClAq at 260° it is changed to (α)-truxillic acid. HNO_3 (S.G. 1.52) forms a di-nitro-derivative [293°].

Salts.— BaA'' 11aq.— CaA'' 3½aq.— CaA'' 6¾aq.— $\text{Ag}_2\text{A}''$: crystalline pp.

Methyl ether $\text{Me}_2\text{A}''$. [126°]. Needles. Mol. w. 332 (calc. 324).

Mono-ethyl ether $\text{C}_{15}\text{H}_{14}(\text{CO}_2\text{H})(\text{CO}_2\text{H})\text{Et}$. [172°]. Formed, together with the di-ethyl ether, by saturating an alcoholic solution of the acid with HCl (Liebermann, *B.* 22, 2240). Needles, yielding AgA' . At 320° it is converted into a mixture of (α)-truxillic acid and (α)-truxillic ether.

Di-ethylether $\text{Et}_2\text{A}''$. [98°]. Needles, v. sol. alcohol (Drory, *B.* 22, 2260).

Mono-piperidine

$\text{C}_{15}\text{H}_{14}(\text{CO.NC}_5\text{H}_{10})(\text{CO}_2\text{H})$. [261°]. Plates (from water or dilute alcohol). Yields MeA' [201°] and a piperidine salt $(\text{C}_5\text{H}_{11}\text{N})\text{HA}'$ 3aq [218°], which crystallises (with 3aq) from alcohol (Herstein, *B.* 22, 2262).

Di-piperidine $\text{C}_{15}\text{H}_{14}(\text{CO.NC}_5\text{H}_{10})_2$. [248°]. Needles, insol. water, sol. alcohol.

Mono-anilide $\text{C}_{15}\text{H}_{11}(\text{CO.NHPh})(\text{CO}_2\text{H})$. [220°]. Formed by heating the acid with aniline (Liebermann, *B.* 26, 838). Needles (from dilute alcohol).

Aniline $\text{C}_{15}\text{H}_{11}(\text{CO.NHPh})_2$. [255°].

Anhydride $\text{C}_{15}\text{H}_{10}\text{O}_4$. Mol. w. 282 (calc. 278). Gives no fluorescein.

(δ)-Truxillic acid $\text{C}_{15}\text{H}_{10}\text{O}_4$. [174°]. Formed by fusing (β)-truxillic acid with potash. Needles (from water), v. sol. alcohol (Liebermann, *B.* 22, 2250; Hesse, *A.* 271, 205). Yields a di-nitro-derivative [226°]. Yields cinnamic acid on distillation.— CaA'' : rosettes of needles.— BaA'' 4aq: prisms, sl. sol. Aq.— CuA'' 2aq.— $\text{Ag}_2\text{A}''$.

Methyl ether $\text{Me}_2\text{A}''$. [77°]. Needles.

Reference.—OXY-TRUXILLIC ACID.

TRUXONE $(\text{C}_6\text{H}_5\text{O})_2\text{C} = 2$ or 3. [289°]. Formed from (α)-truxillic acid and fuming H_2SO_4 (S.G. 1.96) at 15° (Liebermann a. Bergami, *B.* 22, 784; 23, 320). Plates (by sublimation), insol. water, acids, and bases. Not attacked by HNO_3 . Yields $(\text{C}_6\text{H}_5\text{O})_2$ [178°]. Aniline and HOAc on

boiling form the anilide $(C_6H_5 \cdot NPh)_x$ crystallising in needles, $[270^\circ]$, decomposed by fusion.

Phenyl-hydrasine $(C_6H_5 \cdot N_2HPh)_x$. $[c. 270^\circ]$. Needles, v. sl. sol. alcohol.

Oxim $(C_6H_5 \cdot NOH)_x$. Very unstable, easily changing to an anhydride. Boiling Ac_2O yields $(B_6H_5 \cdot NOAc)_x$ $[261^\circ]$, m. sol. HOAc.

TULUCUNIN $C_{20}H_{14}O_4$. Occurs in the bark of *Tarapa Tulucuna* (Caventou, *J. Ph.* [3] 35, 189). Light-yellow amorphous resin, with very bitter taste, sl. sol. water, v. sol. alcohol, insol. ether. Turned blue by cold H_2SO_4 .

TUNGSTATES, and derivatives of; v. TUNGSTEN OXYACIDS, SALTS, AND DERIVATIVES OF, p. 802; also TUNGSTEN TRIO-ACIDS, AND SALTS OF, p. 810.

TUNGSTEN. W. (*Wolfram*.) At. w. 183.6. Mol. w. is unknown. S.G. 18.77 (Waddell, *Am.* 8, 280); 18.77 (Moissan, *C. R.* 116, 1225); 19.13 at 4° (Roscoe, *C. J.* [2] 10, 286); for other determinations v. Bernoulli (*P.* 111, 576), Zettnow (*P.* 111, 16). S.H. (6° to 15°) .035 (De la Rive a. Marcet, *A. Ch.* [2] 75, 113). S.V.S. c. 9.7.

Historical.—In 1785 a new acid was prepared by J. and F. d'Elhujar from the mineral *wolframite*, and shown to be identical with an acid obtained three years before from *tungstein* by Scheele (*Opusc.* 2, 119). The metal of the new acid was isolated by J. and F. d'E. For many years the new metal was known as *wolfram* or *tungsten* (from Swedish = heavy stone); the latter name has gradually driven out the former in England and France, but the metal is generally called wolfram in Germany; the symbol W is universally employed.

Occurrence.—Never uncombined. *Wolframite* (tungstate of Fe and Mn) is found in considerable quantities in Cornwall, Saxony, Bohemia, &c.; *tungstenite*, or *scheelite* (tungstate of Ca), *scheelite* (tungstate of Pb), and some other tungstates occur in various localities; *wolframine* or *wolfram-ochre*, WO_3 , is also found. Some tin ores contain compounds of W, and W is therefore not infrequently found in specimens of tin.

Formation.—1. By reducing WO_3 by heating to redness in H (Berzelius, *P.* 4, 147; Wöhler, *A.* 77, 262; Zettnow, *P.* 111, 16; Roscoe, *C. N.* 25, 61, 78).—2. By heating WO_3 with Na and NaCl (*Z.*, *l.c.*).—3. By reducing WO_3 by mixing with 10 p.c. charcoal and 2 p.c. resin, and heating in a closed crucible for some hours to a white heat (Filsinger, *S. C. I.* 1878. 229).—4. By passing vapour of oxychloride of W and H through a red-hot tube (von Uslar, *A.* 94, 255). 5. By heating WCl_5 in H, in a zinc bath (Roscoe, *l.c.*).—6. By strongly heating the salt $(NH_4)_2WO_4$ in a carbon crucible (Bucholz, *P.* 111, 576).—7. By strongly heating the nitride (*q. v.*, p. 800) in H (Wöhler, *A.* 73, 190).

Preparation.—1. Pure WO_3 is heated to bright redness, in a Pt tube, in a stream of pure dry H (*v. Formation*, No. 1).—2. A mixture of pure WO_3 and dry lampblack is heated in an electric furnace (Moissan, *C. R.* 116, 1225).

WO_3 is prepared from *wolframite* by heating the very finely powdered mineral with conc. $HClAq$, pouring off the solution from time to time and adding more $HClAq$, and after some time adding a little HNO_3Aq until most of the brown solid is changed to yellow $WO_3 \cdot xH_2O$, washing the residue thoroughly by decantation,

adding a considerable quantity of NH_3Aq and warming, filtering from quartz, unchanged *wolframite*, &c., evaporating the solution until small lustrous crystals of an acid ammonium tungstate separate, boiling these crystals for a long time with HNO_3Aq , washing, and heating the residue (Scheibler, *J. pr.* 83, 239; cf. Bernoulli, *P.* 111, 590).

Properties.—A steel-grey, hard, brittle, crystalline powder (Riche, *A. Ch.* [3] 50, 5). By reducing the nitride in H, Wöhler (*A.* 73, 190) obtained W as a black powder. By reducing WO_3 by C in an electric furnace, Moissan (*C. R.* 116, 1228) obtained a lustrous, very hard, greyish white solid. As produced by passing the vapour of WO_3Cl_2 mixed with H through a red-hot tube, W forms a shining, dark steel-grey, mirror-like deposit, which can be detached from the tube in hard, brittle crusts (von Uslar, *A.* 94, 255). W can be melted in the O-H flame, part of it burning to WO_3 (Riche, *l.c.*); or by using a current from 600 Bunsen cells, in an atmosphere of N (Desprez, *C. R.* 29, 549). Considerable masses may be melted by employing the current from a dynamo (*v. Huntington*, *C. N.* 46, 163). W was regarded by Faraday as diamagnetic (*T.* 1846. 49). The emission spectrum is described by Thalén (*A. Ch.* [4] 18, 202). W is unchanged in air, but when the pulverulent metal is heated it burns to WO_3 ; compact W burns in air only at very high temperatures; as obtained by reducing WCl_5 by H, W is said to be pyrophoric. Water is decomposed by W at a red heat. The metal is scarcely acted on by $HClAq$ or H_2SO_4Aq ; it is oxidised by HNO_3Aq to $WO_3 \cdot xH_2O$; the pulverulent metal dissolves slowly in caustic alkali solutions. Finely divided W reduces and ppts. many metals from solutions of their salts. W combines directly with Br, Cl, I, or S. W is not acted on by heating in NH_3 , nor in CO (*v. Rideal*, *C. J.* 55, 45; Smith a. Oberholtzer, *Zeit. f. anorg. Chemie*, 5, 63).

The at. w. of W has been determined (1) by reducing WO_3 in H, and again oxidising W to WO_3 (Berzelius, *P.* 4, 151 [1825]; Schneider, *J. pr.* 50, 158, 161 [1850]; Marchand, *A.* 77, 263 [1850]; von Boroh, *J. pr.* 54, 254 [1851]; Riche, *A. Ch.* [3] 50, 10 [1856]; Dumas, *A. Ch.* [3] 55, 143 [1859]; Bernoulli, *P.* 111, 597 [1860]; Persoz, *A. Ch.* [4] 1, 93 [1864]; Roscoe, *C. N.* 25, 61, 73 [1872]; Waddell, *Am.* 8, 280 [1887]); (2) by determining H_2O in $BaWO_3 \cdot 9H_2O$ (Scheibler, *J. pr.* 83, 324 [1861]); (3) by reducing WO_3 in H and determining H_2O produced (Bernoulli, *P.* 111, 597 [1860]); (4) by analysing Ag_2WO_4 and $FeWO_4$ (Zettnow, *P.* 130, 16, 240 [1867]); (5) by analysing WCl_5 (Roscoe, *C. N.* 25, 61, 73 [1872]); (6) by determining S.H. of W (De la Rive a. Marcet, *A. Ch.* [2] 75, 113 [1840]); (7) by determining V.D. of WCl_5 , WCl_4 , and $WOCl_2$ (*v. these compounds*). The older determinations gave values for at. w. varying from 186 to 189; the most recent determination (by Waddell) gave 184.04; Roscoe's determinations, made by reducing WO_3 to W and oxidising W again to WO_3 , by finding the ratio of WCl_5 to $AgCl$ and to Ag , and by reducing WCl_5 in H, gave values varying from 183.25 to 183.77. The number 183.6 is probably correct to half a unit. The atom of W is pentavalent in the gaseous molecule WCl_5 , and hexavalent in the gaseous molecule WCl_6 .

W is the fourth member (the third is as yet unknown) of the even series, or chromium, family of Group VI. in the periodic arrangement of the elements. W is followed in its family by U, and it succeeds Mo and Cr. W very closely resembles Mo; like that element W is both metallic and non-metallic; the balance of these properties being, however, not quite so evenly maintained in W as in Mo. It is doubtful whether any definite salt has been isolated derived from an oxyacid by replacing H by W. The oxide WO_3 acts as a fairly acidic oxide; like MoO_3 , it is remarkable for the large number of compounds it forms, simultaneously, with oxides that are more basic and oxides that are less basic than itself. The chemical relations of W are discussed in the article CHROMIUM GROUP OF ELEMENTS, vol. ii. p. 168.

Reactions.—1. Heated in air burns to WO_3 ; finely divided W burns easily; compact W only at a very high temperature (v. Roscoe, *C. N.* 25, 61, 73).—2. Heated to redness in steam gives H and oxide ($? WO_3$).—3. Reacts with hot nitric acid, or aqua regia, to form $WO_3 \cdot xH_2O$; the same product is obtained by heating W with conc. sulphuric or hydrochloric acid, but oxides intermediate between WO_3 and WO_2 are formed at first (Riche, *A. Ch.* [3] 50, 15).—4. Pulverulent W dissolves in boiling conc. potash solution, giving H and a tungstate of K (Riche, *l.c.*). 5. Heated in carbonyl chloride to 150° – 200° $WOCl_4$ is produced, mixed with C (Smith a. Oberholtzer, *Zeit. f. anorg. Chemie*, 5, 63).—6. By heating to redness with sulphur chloride a red, crystalline thiochloride, probably $W_2S_2Cl_8$, is formed as a sublimate, unstable in air (S. a. *l.c.*).—7. Finely divided W reduces solutions of several metallic salts; $AgNO_3$ and $AuCl_3$ solutions are reduced to Ag and Au, $HgCl_2$ to $HgCl$, Cu, Pd, Pt and Rh are partially ppd. from solutions; Bi, Cd, and Pb are not ppd. (Smith, *Zeit. f. anorg. Chemie*, 1, 360).

Combinations.—1. Heated in oxygen, WO_3 is formed.—2. Combines with chlorine, to form WCl_4 , at c. 300° ; with bromine, to form WBr_3 , at a higher temperature; and with iodine, to form WI_3 , when strongly heated.—3. Heated with sulphur, forms WS_2 .—4. The compound W_5P_8 is said to be formed by strongly heating W in phosphorus vapour (Wöhler a. Wright, *A.* 79, 244).

Detection and Estimation.—Compounds of W form colourless beads with borax or microcosmic salt in the outer blowpipe flame. The borax bead is yellow in the inner flame if a considerable quantity of a compound of W is present. The microcosmic salt bead is blue in the inner flame in the absence of compounds that themselves form coloured beads; in presence of iron compounds the bead is blood-red, but addition of tin causes it to become blue. Soluble alkali tungstates are formed by fusion with alkali carbonate or nitrate; addition of excess of H_2SO_4 aq, HCl aq, H_3PO_4 aq, H_2UO_4 aq, or $HClO_4$ aq to an aqueous solution of a tungstate, followed by immersion of a piece of zinc in the liquid, produces a blue colour; addition of H_2S to an acidulated solution of a tungstate gives no pp., but a blue colour. According to Mallet (*C. J.* 28, 1228), the successive addition of small pieces of zinc to the solution obtained

by adding excess of conc. HCl aq to an alkaline tungstate produces various colours, the most marked of which is a brilliant magenta-red. By adding KCN aq and then small pieces of zinc to a solution of an alkaline tungstate in excess of conc. HCl aq, a deep green colour is produced; and an amethyst colour is noticed when KCN aq is added to the solution of an alkaline tungstate, the solution is then diluted, HCl aq is then added, and lastly zinc is placed in the liquid. Very minute quantities of W can be detected by adding SO_3 aq and Zn to solution of an alkaline tungstate, whereby a light-blue colour is obtained (M., *l.c.*, p. 1233). W is estimated as WO_3 , obtained by evaporation and strongly heating; for separation from other elements a *Manual of Analysis* must be consulted.

Tungsten, alloys of. By reducing mixtures of WO_3 with oxides of Sb, Bi, Co, Cu, Pb, Ni, or Zn, Bernoulli (*P.* 111, 573) obtained alloys of W with these metals, provided there was not more than 10 p.c. of the foreign metal present. An alloy with aluminium, approximately WAl_3 , was obtained by Wöhler a. Michel (*A.* 115, 102) by heating a mixture of WO_3 , Al, crovolite, and NaCl and KCl. W alloys with iron; v. Poleck a. Grützer (*B.* 26, 35) for an alloy approximately W_2Fe . An alloy of 9 or 10 p.c. W with steel is extremely hard (v. Bernoulli, *l.c.*; Philipp, *Hofmann's Ber. über chem. Industrien*, 745; Le Guen, *C. R.* 56, 593; 59, 786; 63, 967; 64, 619; 68, 592; Caron, *A. Ch.* [3] 68, 143; Osmond, *C. R.* 104, 985; Gruner, *C. R.* 96, 197).

Tungsten, amidonitrides of, v. TUNGSTEN NITRIDES, and ALLIED COMPOUNDS, p. 799.

Tungsten, bromides of. The elements combine when heated together to form WBr_3 , and by partial reduction in H this gives WBr_2 .

TUNGSTEN PENTABROMIDE WBr_5 . The formula is probably molecular, from the analogy of WCl_5 . Prepared by heating W in excess of Br vapour, taking care that every trace of water and O are excluded. Dark, violet-brown needles, resembling I; melts at 276° and boils at 833° , giving off a dark-brown vapour; decomposed on distillation, with separation of Br; moist air or water forms HBr aq and blue oxide of W; heated to 350° in a stream of H, WBr_3 is formed (Roscoe, *C. N.* 25, 73; cf. Borek, *J. pr.* 54, 254; Blomstrand, *J. pr.* 82, 408).

TUNGSTEN DIBROMIDE WBr_2 . Obtained, as a bluish-black, velvety solid, when WBr_3 is heated at c. 350° (in a bath of $ZnCl_2$) in a stream of dry H; WBr_3 , $WOBr_3$, and Br distil over, and WBr_2 remains. Heated above c. 400° in H gives W and HBr ; with HNO_3 aq gives WO_3 , HBr aq, and NH_4NO_3 aq (Roscoe, *l.c.*).

Tungsten, chlorides of. When W is heated in Cl the compound WCl_4 is formed, and by reduction in H or CO , this gives WCl_3 , WCl_2 , and WCl . Great confusion existed about the compositions of the chlorides of W until Roscoe's researches in 1872 established the formulæ.

TUNGSTEN HEXACHLORIDE WCl_6 . Mol. w. 895.82. Prepared by heating W in Cl (Roscoe, *C. N.* 25, 61). The materials must be perfectly dry, and every trace of air must be excluded, else $WOCl_4$ is formed; the WCl_6 sublimes on the cooler part of the tube, and is then distilled several times in a stream of dry Cl, and then in

a current of dry H (a small quantity of WCl_5 is formed, and distils off with the H). Teclu (*A.* 187, 255) obtained WCl_5 by heating W_3 and PCl_5 in a sealed tube at 170° . WCl_5 forms dark-violet crystals; crystallises from CS_2 in brown, six-sided tablets, from POCl_3 in steel-blue, metal-like, regular crystals (*T.*, *l.c.*). Melts, out of contact with air, at 275° , and boils at 346.7° at 760 mm. pressure (*R.*, *l.c.*). V.D. 190 at 350° (Debray, *C. R.* 60, 820; Roscoe, *l.c.*); V.D. 168.8 at 440° (*D.*, *l.c.*; *R.*, *l.c.*; Riebt, *B.* 3, 666). Dissolves readily in CS_2 , or POCl_3 (*T.*, *l.c.*). Distilled in CO_2 gives WCl_5 and Cl; this fact taken in connection with V.D. at 440° shows that at somewhat above b.p. WCl_5 probably dissociates to WCl_3 and Cl. WCl_5 is unchanged in air; but if a trace of WCl_3 is present, HClAq and WO are formed. Hot water produces WO_3 and HClAq . Heated in air, or in O, forms WOCl_4 (Roscoe, *l.c.*; Blomstrand, *J. pr.* 82, 417). WOCl_4 is also formed by heating WO_3 with WCl_5 . WCl_5 interacts with NH_3 , at the ordinary temperature, to form NH_4Cl and W_2N_8 (Rideal, *C. J.* 55, 44).

TUNGSTEN PENTACHLORIDE WCl_5 . Mol. w. 360.45. Prepared by repeatedly heating WCl_5 , somewhat above its b.p. (346.7°) in a stream of dry H, and when a solid residue has been formed removing the WCl_5 from less volatile lower chlorides by heating in CO_2 (Roscoe, *C. N.* 25, 61). Black, lustrous, needle-shaped crystals; very deliquescent; melts at 248° , and boils at 275.6° (*R.*, *l.c.*). V.D. 175.6 to 179.9 at 350° ; 185.7 to 186.4 at 440° (*R.*, *l.c.*). Slightly soluble in CS_2 forming a blue liquid; forms an olive-green solution in water, but is mostly decomposed to HClAq and blue oxide of W. Heated in O forms WOCl_4 and Cl (*R.*, *l.c.*; cf. Blomstrand, *J. pr.* 82, 425; 89, 230).

TUNGSTEN TETRACHLORIDE WCl_4 . This compound is present in the solid residue obtained by heating WCl_5 in H in the preparation of WCl_5 (*v. supra*); it is prepared by distilling this residue, in a bath of H_2SO_4 , in a stream of dry CO_2 , returning the distillate to the distilling vessel and heating again, and repeating these processes several times (Roscoe, *l.c.*). A soft, crystalline, greyish-brown powder; very hygroscopic; has not been fused or volatilised; heated strongly, it gives WCl_5 and WCl_3 . Heated in H to $c. 440^\circ$ pyrophoric W is produced. Decomposed by water to WO_3 and a greenish-brown solution (*R.*, *l.c.*).

TUNGSTEN DICHLORIDE WCl_2 . Prepared by heating WCl_5 in a bath of zinc, in a stream of dry CO_2 ; WCl_5 distils off and WCl_2 remains. A loose, grey, amorphous powder; water forms WO_3 and HClAq , with evolution of H; interacts with H which has been passed through HNO_3Aq to form WO_3 , HCl , and NH_4NO_3 (*R.*, *l.c.*).

Tungsten, cyanides of. No cyanides of W have been isolated; according to Wyruboff (*A. Ch.* [5] 8, 444; cf. Atterberg, *Bl.* [2] 24, 855), compounds containing W, K, and FeCy , are obtained by adding HClAq to a mixture of K tungstates and K ferrocyanide.

Tungsten, fluorides of. No fluoride of W has been isolated. According to Berzelius (*P.* 4, 147), when a solution of $\text{WO}_3\cdot\text{H}_2\text{O}$ in HFAq is evaporated and the residue is treated with water, a solid remains which is free from F after being

heated in NH_3 . According to Riche (*A. Ch.* [3] 50, 41), a solution of tungstic hydroxide in HFAq gives crystals of $\text{WO}_3\cdot\text{H}_2\text{O}$ on evaporation.

Tungstozoxyfluorides. (Fluotungstates.) By dissolving tungstates of the form M^xWO_4 in HFAq , Marignac obtained a series of compounds of the forms $2\text{M}^x\text{F}\cdot\text{WO}_3\cdot x\text{H}_2\text{O}$ and $\text{M}^x\text{F}_2\cdot\text{WO}_3\cdot x\text{H}_2\text{O}$, and also a few compounds of the form $\text{M}^x\text{F}\cdot\text{WO}_3\cdot x\text{H}_2\text{O}$ (*A. Ch.* [3] 69, 67). These compounds may be regarded as salts of the hypothetical acids $\text{H}_2\text{WO}_3\text{F}$ and HWO_3F_2 ; they are similar to some classes of the compounds described as *fluomolybdates* (this vol. p. 425).

The *tungstozoxyfluorides* etch glass even when dry; they react slowly with acids, giving $\text{WO}_3\cdot\text{H}_2\text{O}$. The salts of the forms $\text{M}^x\text{WO}_3\text{F}$ and $\text{M}^x\text{WO}_3\text{F}_2$ were prepared by dissolving M^xWO_4 and M^xWO_3 in HFAq and evaporating; in some cases also by dissolving $\text{WO}_3\cdot\text{H}_2\text{O}$ in HFAq , adding MOH , and evaporating. The salts of the form $\text{M}^x\text{WO}_3\text{F}_2$ were formed by dissolving acid tungstates in HFAq and evaporating. The following compounds were isolated: (1) $\text{M}^x\text{WO}_3\text{F}\cdot x\text{H}_2\text{O}$; $\text{M} = \text{NH}_4$, $x = 0$; $\text{M} = \text{K}$, $x = 1$; $\text{M} = \text{Na}$, $x = 0$; (2) $\text{M}^x\text{WO}_3\text{F}_2\cdot x\text{H}_2\text{O}$; $\text{M} = \text{Zn}$, $x = 10$; (3) $\text{MWO}_3\text{F}_2\cdot x\text{H}_2\text{O}$; $\text{M} = \text{NH}_4$, $x = 1$; $\text{M} = \text{K}$, $x = 1$. The salts $(\text{NH}_4)_2\text{WO}_3\text{F}_2\cdot(\text{NH}_4)_2\text{WO}_3$ and $\text{CuWO}_3\text{F}_2\cdot\text{NH}_3$ were also obtained.

By dissolving $\text{K}_2\text{WO}_4\cdot\text{H}_2\text{O}$ in 4 p.c. $\text{H}_2\text{O}_2\text{Aq}$, and crystallising from dilute $\text{H}_2\text{O}_2\text{Aq}$ containing a little HF, Piccini (*Zeit. f. anorg. Chemie*, 2, 21) obtained $\text{K}_2\text{WO}_3\text{F}_2\cdot\text{H}_2\text{O}$. P. calls this compound *fluoroxypertungstate*; it might also be named *pertungstozoxyfluoride*.

Tungsten, haloid compounds of. When W is heated in a stream of Cl the compound WCl_5 is formed, and this by reduction in H gives WCl_3 , WCl_4 , and WCl_2 . The compound WBr_3 is formed by heating W in Br vapour, and WBr_2 is obtained by partially reducing WCl_5 in H. Small quantities of WI_2 are obtained by heating W in vapour of I. No fluoride of W has been isolated. Oxychlorides and oxybromides of the forms WOX , and WO_2X_2 are obtained by heating W oxides in Cl or Br, and in other ways. The following compounds have been vaporised, and the simplest formulæ are molecular: WCl_3 , WCl_4 , WOCl_2 . The formulæ WBr_3 , WOBr_2 , WO_2Br_2 , and WO_2Br_3 are probably molecular; but if the analogy of the chlorides and bromides of Mo of the form Mo_2X_{2x} is to be followed (*v. vol.* iii. pp. 427, 428) it is probable that the molecular formulæ of the dichloride and dibromide of W are not less than W_2X_4 .

Tungsten, hydroxides of. v. TUNGSTEN OXIDES AND HYDRATED OXIDES (p. 800), also TUNGSTEN OXYACIDS (p. 802).

Tungsten, iodide of, WI_2 . This, the only iodide of W that has been isolated, is obtained, in very small quantities, by passing I vapour, mixed with CO_2 , over red-hot W. It forms a metal-like, greenish crust; heated in air it gives off I and leaves WO_3 ; it is not decomposed by water (Roscoe, *C. N.* 25, 73).

Tungsten, nitrides of; and allied compounds. Compounds of W with N, and probably also with N and H, are formed by heating WCl_5 or WOCl_4 in NH_3 ; the interaction of NH_3 and

WO_3 , probably produces a compound, or compounds, of W, N, H, and O; and a compound of W, N, and O is perhaps formed by heating WO_3 with NH_4Cl .

TUNGSTEN NITRIDES. By passing dry NH_3 over WCl_5 , and washing away the NH_4Cl produced, by water, Rideal (*C. J.* 55, 44) obtained a black lustrous powder, agreeing fairly with the composition W_2N_3 . This substance is insoluble in HNO_3 aq, dilute H_2SO_4 aq, or NaOH aq; hot conc. H_2SO_4 produces NH_3 and WO_3 ; fusion with NaOH forms Na tungstate; heating in air, or with *aqua regia*, oxidises it to WO_3 (*R., l.c.*).

By continued heating WCl_5 in NH_3 , to a temperature difficult to regulate, as slightly too high a temperature produces W, Uhrlaub obtained a black substance to which he gave the formula W_2N_3 (*Die Verbindungen einiger Metalle mit Stickstoff*, Göttingen, 1859).

TUNGSTEN AMIDONITRIDES. By the action of NH_3 on WCl_5 , Wöhler (*A.* 73, 198) obtained a black substance containing from 86.76 to 90.8 p.c. W, and 8.24 p.c. N; W. supposed this substance to be a mixture of two amidonitrides, $2\text{WN}_2 \cdot \text{W}(\text{NH}_2)_2$ and $2\text{WN} \cdot \text{W}(\text{NH}_2)_2$. W. obtained similar black substances, which he did not analyse, by heating chlorides of W with NH_4Cl (*A.* 105, 258).

Compounds of tungsten with N, H, and O. Wöhler (*A.* 73, 198) obtained a black substance by heating WO_3 to dull redness in dry NH_3 ; the percentage of W in this substance varied from 87.65 to 88.47, and it contained 7.15 p.c. N, and c. 2 p.c. H. To this substance W. gave the formula $\text{W}_8\text{N}_{10}\text{H}_4$ ($= 4\text{WN}_2 \cdot \text{W}_2(\text{NH}_2)_2 \cdot 2\text{WO}_2$). Rideal (*C. J.* 55, 44) passed dry NH_3 over WO_3 heated to a dull redness until the yellow WO_3 was changed to a black, amorphous powder; he allowed to cool, and removed excess of NH_3 by passing a current of dry air through the tube. The black substance thus obtained contained 85.26 p.c. W, and 7.4 p.c. N; assuming c. 3 p.c. H, the numbers agreed fairly with the formula $\text{W}_8\text{N}_{10}\text{H}_4$.

Compound of tungsten with N and O. Rideal (*l.c.*) obtained a black powder, agreeing in composition approximately with the formula $\text{WN}_2 \cdot \text{WO}_3$, by heating WO_3 with NH_4Cl until the weight became constant. According to Rideal (*l.c.*) finely divided W does not change when heated in a stream of dry NH_3 , after having been heated to redness in dry H; nor does NH_3 react with the blue oxide of W when heated therewith.

Tungsten, oxides and hydrated oxides of. When powdered W is heated in O it combines to form WO_3 ; by heating this oxide in H a blue oxide is formed, to which various formulae intermediate between WO_3 and WO_2 have been assigned; by further heating in H, or with C, the dioxide WO_2 is produced. There are indications of an oxide with more O than WO_3 . WO_3 dissolves in acids, but corresponding salts have not been isolated; the blue oxide separates from these solutions; WO_3 is also soluble in alkali solutions. WO_3 is insoluble in acids; it dissolves in alkali and alkaline carbonate solutions, forming tungstates (*v. under TUNGSTEN OXYACIDS*, p. 802). WO_3 combines with many acidic oxides to form compounds which react as acids (*v. p.* 801). WO_3 is the anhydride of more than

one tungstic acid (*v. p.* 801). None of the oxides has been vaporised; the mol. w. of none is known.

TUNGSTEN DIOXIDE WO_2 . (*Brown oxide of tungsten.*)

Formation.—1. By heating a mixture of WO_3 and C to redness (Buchholz, *S.* 3, 1).—2. By heating WO_3 to incipient redness in H (Wöhler, *A.* 73, 198; 77, 262).—3. By decomposing WCl_5 , or WCl_4 , by H_2O (Roscoe, *C. N.* 25, 61, 73).—4. By the reaction of Zn and HCl aq on WO_3 (Wöhler, *P.* 2, 345), or on solution of a metatungstate (Riche, *l.c.*).

Preparation.— WO_3 is placed in a porcelain tube closed at one end and provided with a long opening in the middle; this tube is placed inside another porcelain tube which is kept at red heat, while H is passed through as long as water continues to be formed (Wöhler, *A.* 77, 262 note); the product is allowed to cool in H, and is kept in H for 24 hours (Riche, *A. Ch.* [3] 50, 29).

Properties.—A brown powder with a slight violet sheen; prepared by reducing WO_3 by Zn and HCl aq, the oxide is obtained in metal-like lustrous crystals, pseudomorphs of WO_3 . *S.G.* 12.11 (Karsten, *S.* 65, 394).

Reactions.—1. Moist WO_3 oxidises rapidly in air to WO_3 ; as prepared by reducing WO_3 in H it is pyrophoric, but if allowed to cool slowly in H the product is not pyrophoric (Berzelius, *P.* 4, 147; 8, 267; Wöhler, *l.c.*; Riche, *l.c.*).—2. Heated strongly in hydrogen gives W.—3. Chlorine forms WO_2Cl_2 when heated with WO_2 (Roscoe, *l.c.*, p. 63).—4. Heated to dull redness in a stream of ammonia, a compound, or compounds, of W with N, H, and O is formed (*v. Compounds of W with N, H, and O, under TUNGSTEN NITRIDES, supra*).—5. By heating with *sal ammoniac*, Rideal (*C. J.* 55, 44) obtained a black powder approximately $\text{WN}_2 \cdot \text{WO}_3$ (*v. Compound of W with N and O, supra*).—6. Moist WO_2 dissolves easily in warm hydrochloric or sulphuric acid, forming reddish-brown solutions from which blue oxide of W separates. WO_2 prepared in the dry way is scarcely acted on by acids, except *aqua regia*, which oxidises it to WO_3 .—7. WO_2 dissolves in conc. *potash* solution, giving off H, and forming K tungstate. 8. Reduces mercuric chloride to HgCl , and ppts. Cu_2O from solutions of copper salts (Riche, *A. Ch.* [3] 50, 5).—9. Heated in nitric oxide to below 500° gives the blue oxide; oxidised to WO_3 by heating in nitrogen dioxide to c. 800° (Sabatier & Senderens, *C. R.* 114, 1429; 115, 236).

BLUE OXIDE OF TUNGSTEN. Blue compounds of W and O are obtained by heating WO_3 with reducing agents; analyses lead to formulae such as W_2O_5 , W_3O_8 , or W_4O_{11} , intermediate between WO_2 and WO_3 . Malaguti (*A. Ch.* [2] 60, 279) gave the formula W_2O_5 to the blue product of heating WO_3 in H to c. 250° ; von Uslar (*Beiträge zur Kenntniss des W und Mo* [Göttingen, 1855]) gave the formula W_3O_8 . Gmelin said that a blue oxide of the composition W_4O_{11} is formed by strongly heating WO_3 in CO.

Blue compounds are also obtained by strongly heating NH, tungstates out of contact with air (Malaguti, *l.c.*; von Uslar, *l.c.*). Aqueous solutions of WO_3 or tungstates are coloured blue by the action of very weak reducers, e.g. by exposing moist WO_3 on paper to sunlight (Liesegang,

C. C. 1865. 943), or by the action of SnCl_2Aq on tungstates (Bunsen, *A.* 188, 289; v. also Scheibler, *J. pr.* 83, 318). Conc. H_2SO_4 or HClAq gives a blue colour when heated with W (Riche, *A. Ch.* [3] 50, 15). Tungstates boiled with acetic acid and then electrolysed give blue coloured substances (Smith, *B.* 13, 753).

PEROXIDES OF TUNGSTEN. Fairley (*C. J.* 31, 141) obtained indications of an oxide with more O than WO_3 , by dissolving $\text{WO}_3 \cdot 2\text{H}_2\text{O}$ in $\text{H}_2\text{O}_2\text{Aq}$, and evaporating over H_2SO_4 *in vacuo*; the green, transparent, yellow scales thus obtained dissolved in water, forming a solution which could be titrated with KMnO_4Aq , with separation of $\text{WO}_3 \cdot x\text{H}_2\text{O}$. Cammerer (*Chem. Zeitung*, 15, 957) found that WO_3 dissolved in boiling $\text{H}_2\text{O}_2\text{Aq}$, with evolution of O; on spontaneous evaporation he obtained a yellow powder, to which he gave the formula $\text{WO}_3 \cdot \text{H}_2\text{O}_2$ (cf. reaction of $\text{H}_2\text{O}_2\text{Aq}$ with $\text{Cr}_2\text{O}_3\text{Aq}$, vol. ii. p. 166). According to Péchard (*C. R.* 112, 1060), a salt $\text{Na}_2\text{O} \cdot \text{W}_2\text{O}_7 \cdot 2\text{H}_2\text{O}$ is formed by boiling Na paratungstate solution with $\text{H}_2\text{O}_2\text{Aq}$ and evaporating *in vacuo*.

TUNGSTEN TRIOXIDE WO_3 . (*Tungstic anhydride*. Sometimes erroneously called *tungstic acid*.)

Occurrence.—As *tungstic ochre* or *wolframite* in Cumberland, Connecticut, North Carolina, &c.

Formation.—1. By strongly heating in air tungstate of NH_4 or of Hg^+ .—2. By strongly heating $\text{WO}_3 \cdot x\text{H}_2\text{O}$.—3. By burning W in air or O.

Preparation.—An aqueous solution of commercial Na_2WO_4 is poured into boiling HClAq (1:1); the ppd. WO_3 is washed with HClAq until NaCl is completely removed; it is then washed with water to remove all HCl, and dissolved in NH_4Aq ; the solution is evaporated to dryness, and the NH_4 salt thus obtained is heated in an open crucible until every trace of NH_3 is driven off (Roscoe, *C. N.* 25, 73). Bernoulli (*P.* 111, 590) recommends to boil the NH_4 salt for a long time with successive quantities of HNO_3Aq (to remove traces of Na salts), and to wash the residual WO_3 quite free from acids (cf. Zettnow, *P.* 130, 16, 240). WO_3 is obtained in crystals by very strongly heating the amorphous oxide (Bernoulli, *P.* 111, 595; Schafarik, *W. A. B.* 47, 246); by dissolving WO_3 in molten borax (Nordenskjöld, *P.* 114, 612); by strongly heating the oxide in a current of HCl (Debray, *C. R.* 55, 287); or by heating to whiteness a mixture of Na_2WO_4 and Na_2CO_3 imbedded in NaCl, when crystals of WO_3 sublime (*D.*, l.c.).

Na_2WO_4 may be prepared from *wolframite* by heating a mixture of 150 pts. of the finely powdered mineral with 100 pts. calcined Na_2CO_3 and 15 pts. NaNO_3 , for four or five hours, in an iron vessel, lixiviating with water and crystallising (v. Franze, *J. pr.* [2] 4, 238; cf. Huntington, *B.* 17, 203; Scheibler, *J. pr.* 83, 239).

Waddell (*Am.* 8, 880) prepares pure WO_3 from *tungstenite*, by treating the powdered mineral with *aqua regia*, washing the residue, fusing it with KHSO_4 , dissolving in water, and fractionally ppg. by HgNO_3Aq ; the first pps. are then decomposed by *aqua regia*, the WO_3 thus obtained is dried and fused with Na_2CO_3 , the fused mass is dissolved in water, tartaric acid is added, and H_2S is passed into the solution; the filtrate

from ppd. MnS , &c., is boiled till H_2S is expelled, and is then fractionally ppd. by HgNO_3Aq ; the later pps. are collected, washed, and decomposed by heating in an open vessel. For a method of preparing WO_3 from *wolframite* v. *Preparation of Tungsten*, p. 797.

Properties.—A heavy, canary-yellow powder; becoming orange-coloured when heated (Roscoe, *C. N.* 25, 73). Crystalline WO_3 is described as wine-yellow, very lustrous, rhombic tablets (Nordenskjöld, *P.* 114, 612). A trace of Na tungstate gives a green colour to WO_3 (*R.*, l.c.). S.G.: amorphous, 7.13 to 7.16 (Zettnow, *P.* 130, 16, 240; Karsten, *S.* 65, 394); crystalline, 7.23 at 17° (*Z.*, l.c.); 6.38 (*N.*, l.c.). S.H. (8° to 98°) .07983 (Regnault, *A. Ch.* [3] 1, 129); (22° to 52°) .0894 (Kopp, *T.* 1865. 71). Melts readily in the blowpipe (Riche, *A. Ch.* [3] 50, 29); can be sublimed by mixing with Na_2CO_3 and heating to whiteness (Debray, *C. R.* 55, 287); also by strongly heating in HCl (Schafarik, *W. A. B.* 47, 246). Not decomposed at m.p. of Pt (c. 1750°) (Read, *C. J.* 65, 313 [1894]). On exposure to light WO_3 turns greenish, owing to partial reduction (Roscoe, l.c.; cf. Liesegang, *C. C.* 1865. 943). WO_3 is insoluble in water or acids, even in boiling conc. H_2SO_4 ; it dissolves in hot KOH Aq , NH_4Aq , or $\text{K}_2\text{CO}_3\text{Aq}$, also in molten K_2CO_3 , KHSO_4 , or K_2WO_4 ; also in molten alkali chlorides, in air, with evolution of Cl (Schultze, *J. pr.* [2] 21, 437, 441). WO_3 acts as an acidic oxide, forming tungstates (v. **TUNGSTEN OXYACIDS**, p. 802).

Reactions.—1. Heated in hydrogen, WO_3 is reduced to the blue oxide, then to WO_2 , and finally to W (v. **BLUE OXIDE OF TUNGSTEN**, p. 800; **TUNGSTEN DIOXIDE**, p. 800; and **TUNGSTEN**, p. 797).—2. Reduction to WO_2 or W is effected by heating with carbon.—3. Heated with potassium or sodium, WO_3 gives W.—4. Reduction to the blue oxide, and then to WO_2 , is brought about by zinc and hydrochloric acid, by stannous chloride, and also by heating with water and different organic compounds.—5. Heating with carbon in chlorine produces WO_2Cl_2 and WOCl_4 .—6. WOCl_4 is formed by passing vapour of tungsten hexachloride over heated WO_3 (Roscoe, *C. N.* 25, 63).—7. A mixture of WO_3 and calcium chloride heated to redness in carbon dioxide gives WO_2Cl_2 (Schultze, *J. pr.* [2] 21, 441).—8. Mixed with carbon and heated in bromine, WO_3 gives WOBr_4 ; and WO_2Br_2 is formed by passing vapour of tungsten pentabromide over hot WO_3 (Roscoe, l.c. p. 73).—9. WO_3 is said to dissolve in molten alkali chlorides, in air, giving off Cl; heated in absence of air (in a stream of CO_2) with chloride of calcium, cobalt, iron, magnesium, or nickel, it is said to give WO_2Cl_2 and MWO_2 (Schultze, l.c.).—10. Heating with phosphorus pentachloride produces WCl_5 and POCl_3 (Teclu, *A.* 187, 255); but WO_2Cl_2 and WOCl_4 are also formed, according to the relative masses of WO_3 and PCl_5 , and the temperature (Schiff, *A.* 197, 185).—11. WO_2Cl_2 , WOCl_4 , and CO_2 are formed by heating WO_3 in vapour of carbon tetrachloride (Watts & Bell, *C. J.* 83, 442).—12. Compounds of W with N, H, and O (v. p. 800) are formed by heating WO_3 in ammonia; and a compound of W with N and O is probably produced by heating WO_3 with sal ammoniac (v. p. 800).—13. WS_2

is formed by passing sulphur vapour, or hydrogen sulphide, over WO_3 heated to whiteness (Berzelius); also by heating to redness a mixture of WO_3 with 6 pts. of mercuric sulphide (B.; Brock, *J. pr.* 54, 254).

HYDRATES OF TUNGSTEN TRIOXIDE. Various compounds of the form $\text{WO}_3 \cdot x\text{H}_2\text{O}$ have been isolated; as these compounds act as acids, they are described under TUNGSTEN OXYACIDS.

Tungsten oxyacids, salts, and derivatives of. Several hydrates of WO_3 that react as acids are known. WO_3 also combines with many acidic oxides—such as P_2O_5 , B_2O_3 , SiO_2 , &c.—and the compounds so formed combine with basic oxides to form salt-like bodies.

TUNGSTIC ACIDS. The hydrates of WO_3 fall into two classes: *tungstic acids*, which are insoluble, or nearly insoluble, in water; and *metatungstic acids*, which dissolve in water.

TUNGSTIC ACIDS. The monohydrate $\text{WO}_3 \cdot \text{H}_2\text{O}$, or *orthotungstic acid* $\text{WO}_3(\text{OH})$, is obtained by dissolving WO_3 in hot alkali or alkaline carbonate solutions, and boiling these solutions with excess of a mineral acid. It is also said to be obtained by decomposing an ammoniacal solution of WO_3 by Cl (Dumas, *A. Ch.* [3] 55, 144); and also by boiling powdered wolframite with *aqua regia*. This acid is a yellow solid; it reddens litmus; is insoluble, or almost insoluble, in water. According to Braun (*J. pr.* 91, 39), it is changed to $2\text{WO}_3 \cdot \text{H}_2\text{O}$ at 100° ; according to Zettnow (*P.* 130, 16, 240), this change is effected at 50° . The acid is slowly reduced by Zn and HClAq , the final product being WO_2 (O. v. d. Pfordten, *B.* 16, 508).

The dihydrate $\text{WO}_3 \cdot 2\text{H}_2\text{O}$ is said to be formed by adding a mineral acid to a dilute solution of an alkali tungstate M_2WO_4 , and drying in the air; also by decomposing WCl_5 , WOCl_4 , or WO_2Cl_2 by water (Forcher, *W. A. B.* 44 [2], 173; cf. Riche, *A. Ch.* [3] 50, 86; Anthon, *J. pr.* 9, 6). Forms $\text{WO}_3 \cdot \text{H}_2\text{O}$ by drying over H_2SO_4 (Braun, *J. pr.* 91, 39). This hydrate is described as an amorphous, white solid; reddens litmus; somewhat soluble in water, but insoluble if a little acid is present. By boiling with dilute acids is said to give $\text{WO}_3 \cdot \text{H}_2\text{O}$.

The hemihydrate $2\text{WO}_3 \cdot \text{H}_2\text{O}$, or *ditungstic acid* $\text{H}_2\text{W}_2\text{O}_7$, is said by Braun (*l.c.*) to be formed by heating the monohydrate to 190° ; the change is complete at 50° according to Zettnow (*P.* 130, 16, 240).

METATUNGSTIC ACIDS. Acids of the composition $4\text{WO}_3 \cdot x\text{H}_2\text{O}$ are obtained by decomposing hot conc. $\text{BaW}_2\text{O}_7\text{Aq}$ by the equivalent quantity of H_2SO_4 , filtering from BaSO_4 , and evaporating (Scheibler, *J. pr.* 83, 310); also by decomposing $\text{PbW}_2\text{O}_7\text{Aq}$ by H_2S , filtering, and evaporating (Forcher, *W. A. B.* 44 [2], 173). The composition of the acid formed by evaporating *in vacuo* over H_2SO_4 is probably $\text{H}_2\text{W}_2\text{O}_7 \cdot 7\text{H}_2\text{O}$ (Scheibler, *l.c.*; cf. Person, *C. R.* 34, 185; Lotz, *A.* 91, 52). BaW_2O_7 is obtained by ppg. a hot conc. solution of $(\text{NH}_4)_2\text{W}_2\text{O}_7$ by BaCl_2Aq ; PbW_2O_7 by ppg. $(\text{NH}_4)_2\text{W}_2\text{O}_7\text{Aq}$ by $\text{Pb}(\text{C}_2\text{H}_3\text{O}_2)_2\text{Aq}$; $(\text{NH}_4)_2\text{W}_2\text{O}_7$ is formed by boiling $(\text{NH}_4)_2\text{WO}_4$ with WO_3Aq and evaporating.

According to Zettnow (*P.* 130, 16, 240), the pp. obtained by decomposing $\text{Na}_2\text{WO}_4\text{Aq}$ by a mineral acid has the composition $4\text{WO}_3 \cdot \text{H}_2\text{O}$ ($= \text{H}_2\text{W}_2\text{O}_7$) after drying at 200° .

Metatungstic acid crystallises in sulphur-yellow octahedra; the acid is readily soluble in water, forming a very sour, intensely bitter liquid. A conc. solution gives a pp. of $\text{WO}_3 \cdot 2\text{H}_2\text{O}$ on standing; when a dilute solution is boiled it coagulates and gives a pp. of white $\text{WO}_3 \cdot 2\text{H}_2\text{O}$, and then of yellow $\text{WO}_3 \cdot \text{H}_2\text{O}$. The heats of neutralisation of $\text{H}_2\text{W}_2\text{O}_7\text{Aq}$ by Na_2OAq , K_2OAq , BaOAq , and SrOAq are given by Péchard (*C. R.* 108, 1167); the values are nearly the same as those for HNO_3Aq and $\text{H}_2\text{SO}_4\text{Aq}$. When four equivalents of base are added to $\text{H}_2\text{W}_2\text{O}_7\text{Aq}$, orthotungstates M_2WO_4 are formed (*P.*, *l.c.*).

By long-continued boiling 2 pts. Na_2WO_4 with 1 pt. As_2O_3 , evaporating, treating with alkali solution, and repeatedly crystallising, Lefort (*A. Ch.* [5] 25, 205) obtained fine, very lustrous crystals, which were very soluble in water and in alcohol; to this acid L. gave the composition $\text{H}_2\text{W}_2\text{O}_7 \cdot 6\text{H}_2\text{O}$, and the name *luteo-metatungstic acid*.

Colloidal (meta?) tungstic acid. By adding to 5 p.c. $\text{Na}_2\text{WO}_4\text{Aq}$ rather more HClAq than sufficed to neutralise the Na , and dialysing, with addition from time to time of a little HClAq , Graham (*C. J.* 17, 318) obtained a solution in water of tungstic acid. The solution was not gelatinised by acids, salts, or alcohol at the ordinary temperature; it remained clear at 200° . According to Sabanéeff (*J. R.* 21, 515; Abstract in *C. J.* 58, 1215), determinations of the freezing-point of an aqueous solution of Graham's soluble acid point to the formula $3\text{WO}_3 \cdot \text{H}_2\text{O}$ ($= \text{H}_3\text{W}_3\text{O}_9$). As the values for mol. w. obtained by S. varied from 679 to 995, there seems little reason for adopting the formula $\text{H}_2\text{W}_2\text{O}_7$ (718) rather than $\text{H}_3\text{W}_3\text{O}_9$ (944).

TUNGSTATES. A great many tungstates have been prepared. The proportion of basic to acidic radicle varies much in these compounds. The better studied tungstates have been divided into three classes—*orthotungstates* MO_2WO_4 , *paratungstates* $8\text{MO}_2\text{WO}_7$, or perhaps $5\text{MO}_2\text{WO}_7$, and *metatungstates* MO_4WO_4 —but as many tungstates are known which do not fit into any of these classes it seems better to adopt a nomenclature and arrangement similar to those employed for the molybdates (*cf.* vol. iii. p. 423), based on the number of WO_4 radicles in the salts. Arranging the tungstates on this plan we get the following table. R = divalent metal, or two atoms of a monovalent metal.

(Ortho) *Monotungstates* RO_2WO_4 , or RWO_4 ; derived from the acid H_2WO_4 .

Ditungstates RO_2WO_7 , or RW_2O_7 ; derived from the acid $\text{H}_2\text{W}_2\text{O}_7$.

(Para) $\left\{ \begin{array}{l} 3:7 \text{ tungstates } 3\text{RO}_2\text{WO}_7 \text{ or } \text{R}_3\text{W}_3\text{O}_{21} \\ 5:12 \text{ tungstates } 5\text{RO}_2\text{WO}_7 \text{ or } \text{R}_5\text{W}_5\text{O}_{25} \end{array} \right.$

$2:5 \text{ tungstates } 2\text{RO}_2\text{WO}_7 \text{ or } \text{R}_2\text{W}_2\text{O}_{14}$

$3:8 \text{ tungstates } 3\text{RO}_2\text{WO}_7 \text{ or } \text{R}_3\text{W}_3\text{O}_{24}$

Triitungstates RO_3WO_7 , or RW_3O_{10} ; ? derived from Graham's colloidal acid.

(Meta) *Tetratungstates* RO_4WO_7 , or RW_4O_{13} ; derived from the acid $\text{H}_4\text{W}_4\text{O}_{20}$.

Pentatungstates RO_5WO_7 , or RW_5O_{18} .

Hexatungstates RO_6WO_7 , or RW_6O_{23} .

Octotungstates RO_8WO_7 , or RW_8O_{31} .

The tungstates which have been most thoroughly examined are the *monotungstates* or *orthotungstates*; the *paratungstates*, which

are either 3:7 or 5:12 salts; and the tetra- or metatungstates.

For *thiotungstates v. TUNGSTEN, THIO-ACIDS AND SALTS OF*, p. 810.

ORTHOTUNGSTATES or **MONOTUNGSTATES**, RO.WO_3 or RWO_4 . Salts of H_2WO_3 , which is the monohydrate of WO_3 . The alkali orthotungstates are obtained by dissolving WO_3 or $\text{WO}_3 \cdot \text{H}_2\text{O}$ in alkali or alkali-carbonate solutions; or by fusing WO_3 with alkalis, alkaline carbonates, or alkali acid sulphates, and dissolving in water. The other orthotungstates are generally obtained from solutions of the alkali salts by ppn.; also by strongly heating WO_3 with metallic oxides or carbonates; also by fusing the alkali salts with metallic chlorides, and washing with water (Manross, *A. 81*, 243; *82*, 356; Geuther a. Forsberg, *A. 120*, 268; Schultze, *A. 126*, 56). The orthotungstates are insoluble in water, except the alkali salts and the Mg salt. Solutions of the alkali salts give pps. of $\text{WO}_3 \cdot \text{H}_2\text{O}$ (yellow) or $\text{WO}_3 \cdot 2\text{H}_2\text{O}$ (white), with dilute $\text{H}_2\text{SO}_4\text{Aq}$, HClAq , HNO_3Aq , or $\text{H}_3\text{PO}_4\text{Aq}$; the pp. by HClAq dissolves in a considerable excess of conc. HClAq (Mallet, *C. J. 28*, 1228); cold solutions of metatungstates are not ppd. by acids. Accordi₃ to Marignac (*A. Ch.* [3] 69, 6) the pp. obtained by adding an acid to a solution of an alkali tungstate sometimes contains alkali, and sometimes the ppg. acid, according to the relative quantity of acid used, the dilution, and probably also the temperature. Orthotungstates which are insoluble in water, and the metals of which form carbonates that are insoluble in alkali carbonate solutions, can be brought into solution by fusion with alkali carbonates and treatment with water.

Solutions of orthotungstates give a white pp. with HgNO_3Aq ; a bluish-white pp. with $\text{Cu}(\text{NO}_3)_2\text{Aq}$; a brown flocculent pp. on adding $\text{K}_2\text{FeCy}_3\text{Aq}$, after adding HClAq ; no pp. with tincture of galls until an acid is added, when a copious chocolate-coloured pp. is formed; and a yellow pp. with SnCl_4Aq , which pp. turns blue when it is warmed with a little HClAq or $\text{H}_2\text{SO}_4\text{Aq}$. For the reactions with Zn and acid, and with KCNSAq , Zn and acid, *v. TUNGSTEN, DETECTION OF*, p. 798.

Barium orthotungstate BaWO_4 . Prepared by fusing 7 parts BaCl_2 with 4 parts NaCl and 2 parts Na_2WO_4 , and washing with water; white octahedra (Geuther a. Forsberg, *A. 120*, 270); fusible with difficulty (Zettnow, *P. 130*, 256); S.G. 5.0035 at 13.5° (Clarke, *Am. S.* [3] 14, 281). *Hydrates*: (1) $2\text{BaWO}_3 \cdot \text{H}_2\text{O}$, by ppg. a hot solution of $3\text{Na}_2\text{O} \cdot 7\text{WO}_3$, by BaOAq (Scheibler, *B. 1860*. 208); (2) $\text{BaWO}_3 \cdot \text{H}_2\text{O}$ and $\text{BaWO}_3 \cdot 2\text{H}_2\text{O}$, by adding four equivalents BaO in solution to $\text{H}_2\text{W}_2\text{O}_7\text{Aq}$ (Péchar, *C. R.* 108, 1167).

Cadmium orthotungstate CdWO_4 . Obtained as a yellow crystalline powder by fusing together 11 parts CdCl_2 , 16 parts NaCl , and 4 parts Na_2WO_4 (G. a. F., *l.c.*, p. 268; Z., *l.c.*, p. 240). The *dihydrate* $\text{CdWO}_3 \cdot 2\text{H}_2\text{O}$ is obtained by ppg. a solution of a salt of Cd by $\text{Na}_2\text{WO}_4\text{Aq}$ (Anthon, *J. pr.* 8, 399; 9, 337; Smith a. Bradbury, *B. 24*, 2935).

Calcium orthotungstate CaWO_4 . Occurs native as *scheelite*, S.G. 6.02 (Bernoulli, *J. 13*, 783). Obtained by adding K_2WO_4 to CaCl_2Aq . Quadratic octahedra are formed by fusing

Na_2WO_4 with excess of CaCl_2 (Manross, *A. 81*, 243; *82*, 348); also by heating the ppd. salt with CaO in a stream of HCl (Debray, *C. R.* 55, 287).

Chromium orthotungstate $\text{Cr}_2(\text{WO}_4)_3 \cdot 20\text{H}_2\text{O}$. Obtained as a green pp. by adding $\text{Na}_2\text{WO}_4\text{Aq}$ to CrCl_3Aq ; loses $13\text{H}_2\text{O}$ at 100° (Lotz, *A. 91*, 66).

Cobalt orthotungstate $\text{CoWO}_3 \cdot 2\text{H}_2\text{O}$. A violet powder; obtained by ppg. Co salt solutions by $\text{K}_2\text{WO}_4\text{Aq}$ (Anthon, *J. pr.* 9, 344).

Copper orthotungstate $\text{CuWO}_3 \cdot 2\text{H}_2\text{O}$. A green powder, melting at a red heat and cooling to chocolate-coloured crystals; formed by ppg. Cu salts by $\text{Na}_2\text{WO}_4\text{Aq}$ (A., *l.c.*).

Ferrous orthotungstate FeWO_4 . Obtained as opaque crystals by heating WO_3 and Fe_2O_3 in a stream of HCl (Debray, *C. R.* 55, 288); also by fusing 2 parts FeCl_3 , 2 parts NaCl , and 1 part Na_2WO_4 (Geuther a. Forsberg, *A. 120*, 273; Zettnow, *P. 130*, 30). The *trihydrate* $\text{FeWO}_3 \cdot 3\text{H}_2\text{O}$ was obtained by Anthon (*J. pr.* 9, 343) as a brown powder by ppg. a ferrous salt by $\text{K}_2\text{WO}_4\text{Aq}$. *Double compounds* of the form $m\text{FeWO}_4 \cdot n\text{MnWO}_4$ with the ratios $m:n=7:1$, $4:1$, $3:1$, $3:2$, $1:2$, and $1:7$ were obtained by fusing FeCl_3 , MnCl_2 , NaCl , and Na_2WO_4 in varying proportions (G. a. F., *l.c.* p. 270; cf. Z., *l.c.* p. 250). *Wolframite* has approximately the composition $\text{FeO} \cdot \text{MnO} \cdot \text{WO}_3$.

Lead orthotungstate PbWO_4 . Occurs native as *scheelite*; obtained, as a white pp., by adding $\text{K}_2\text{WO}_4\text{Aq}$ to solution of a salt of Pb (A., *l.c.*, p. 342); quadratic octahedra are formed by fusing 10 parts Na_2WO_4 with 47 parts PbCl_2 , S.G. 8.235 (Manross, *A. 82*, 357).

Magnesium orthotungstate MgWO_4 . Formed, in white octahedra, by fusing 2 parts MgCl_2 with 2 parts NaCl and 1 part Na_2WO_4 (G. a. F., *l.c.* p. 272).

Manganese orthotungstate MnWO_4 . Garnet-brown, lustrous, rhombic crystals; S.G. 6.7; obtained by fusing 2 parts MnCl_2 , 2 parts NaCl , and 1 part Na_2WO_4 (G. a. F., *l.c.*; Z., *l.c.*).

Mercurous orthotungstate Hg_2WO_4 . A yellow pp., formed by adding solution of a mercurous salt to solution of an alkali tungstate (A., *l.c.*).

Nickel orthotungstate NiWO_4 . Formed by fusing 2 parts NiCl_2 with 2 parts NaCl and 1 part Na_2WO_4 ; brown, lustrous crystals (Schultze, *A. 126*, 56); S.G. 6.8845 at 20.5° , 6.8522 at 22° (Clarke, *Am. S.* [3] 14, 281). The *hexahydrate*, $\text{NiWO}_3 \cdot 6\text{H}_2\text{O}$, is obtained by ppn. (A., *l.c.*).

Potassium orthotungstate K_2WO_4 . White, triclinic needles; obtained by boiling WO_3 with an equivalent weight of KOH or $\text{K}_2\text{CO}_3\text{Aq}$, and evaporating (Marignac, *A. Ch.* [3] 69, 18; Anthon, *J. pr.* 8, 399; 9, 337). Decomposes when heated; melts at red heat (M., *l.c.*), taking up CO_2 (Ullik, *W. A. B.* 56 [2], 148; cf. Knorre, *J. pr.* 27, 89). Various *hydrates* are obtained by crystallising a solution of WO_3 in $\text{K}_2\text{CO}_3\text{Aq}$ under different conditions (M., *l.c.*; A., *l.c.*; Riche, *A. Ch.* [3] 50, 45).

Silver orthotungstate Ag_2WO_4 . A pale-yellow, amorphous pp. by adding $\text{Na}_2\text{WO}_4\text{Aq}$ to solution of a salt of Ag; melts below redness, and becomes crystalline on cooling; easily soluble in HNO_3Aq ; soluble in NH_3Aq (Zettnow, *P. 130*, 30; cf. Muthmann, *B. 20*, 984; Wöhler a.

Rautenberg, *A.* 114, 120). By evaporating a solution in NH_4Aq over CaO and NH_4Cl , Widmann obtained the compound $\text{Ag}_2\text{WO}_4 \cdot 4\text{NH}_3$ (*Bl.* [2] 20, 64).

Sodium orthotungstate $\text{Na}_2\text{WO}_4 \cdot 2\text{H}_2\text{O}$. Obtained by crystallising a solution of WO_3 in the equivalent quantity of NaOHAq or $\text{Na}_2\text{CO}_3\text{Aq}$. Transparent, colourless, rhombic tablets (Marignac, *A. Ch.* [3] 69, 22). Effloresces *in vacuo*, or in dry air. Loses all H_2O at 100° . S.G. 3.2588 at 17.5° , 3.2314 at 19° ; S.G. of $\text{Na}_2\text{WO}_4 = 4.1743$ at 20.5° , 4.1833 at 18.5° (Clarke, *Am. S.* [3] 14, 281). Solubility = 41 at 0° , 55 at 15° , 123.4 at 100° (Riche, *J. pr.* 69, 10). For S.G. of $\text{Na}_2\text{WO}_4\text{Aq}$ of different concentrations, v. Franz (*J. pr.* [2] 4, 238). For E.C. of $\text{Na}_2\text{WO}_4\text{Aq}$ v. Walden (*Z. P. C.* 1, 529).

Strontium orthotungstate SrWO_4 . Obtained by ppn (Anthon, *l.c.*); also by fusing 2 parts SrCl_2 , 2 parts NaCl , and 1 part Na_2WO_4 (Zettnow, *l.c.*; Schultze, *A.* 126, 56).

Zinc orthotungstate ZnWO_4 . Colourless tablets; formed by fusing 2 parts ZnCl_2 with 2 parts NaCl and 1 part Na_2WO_4 (Geuther a. Forsberg, *A.* 120, 270; cf. Zettnow, *P.* 130, 240).

PARATUNGSTATES. A number of acid tungstates have been isolated, the composition of which is expressed by one of the formulæ $3\text{RO} \cdot 7\text{WO}_3$ or $5\text{RO} \cdot 12\text{WO}_3$. The former formula was given by Lotz (*A.* 91, 49) and Scheibler (*J. pr.* 83, 273); the latter formula by Laurent (*A. Ch.* [3] 21, 54) and Marignac (*A. Ch.* [3] 69, 5). The two formulæ represent salts of almost identical composition, and no way has been found of deciding which formula is the better (cf. Knorre, *J. pr.* [2] 27, 83). The acid tungstates of this series are more easily formed and crystallise better than the other acid salts; they are generally called *paratungstates*, following the suggestion made by Marignac.

The alkali paratungstates are obtained by saturating hot alkali solutions with WO_3 and crystallising; most of the other paratungstates are prepared by ppn. from solutions of the alkali salts. The alkali salts are soluble in water, the other salts are insoluble. Solutions of alkali paratungstates give, with dilute HClAq , white pps. which become yellow on boiling ($\text{WO}_3 \cdot x\text{H}_2\text{O}$). Metatungstates, RO_4WO_3 , are formed by gradually adding HClAq to boiling solutions of paratungstates; meta-salts are also formed by boiling para-salts with $\text{WO}_3 \cdot \text{H}_2\text{O}$. Solutions of paratungstates are not ppd. by SO_4Aq , HIAq , citric, tartaric, or oxalic acid; but the presence of one of these acids does not hinder ppn. by HClAq . Solutions of alkali paratungstates give pps. with salts of almost all the heavy metals. H_2S reacts with alkali paratungstates in solution to form solutions of thio-tungstates which give brown pps. with acids, soluble in $(\text{NH}_4)_2\text{SAq}$. Paratungstates readily react with H_3PO_4 , H_3AsO_4 , &c., to form complex acids (v. p. 807), solutions of which are not ppd. by acids, except these are added in considerable excess; solutions of paratungstates are, therefore, not ppd. by HClAq in presence of H_3PO_4 , H_3AsO_4 , $\text{H}_2\text{B}_4\text{O}_7$, &c. For the reactions of paratungstates with PtO_2H , v. Rosenheim (*B.* 24, 2897; the reaction is rather indefinite).

If the simpler (8:7) formula is adopted, the

paratungstates are represented as $3\text{R}^1_2\text{O} \cdot 7\text{WO}_3$, $3\text{R}^{II}\text{O} \cdot 7\text{WO}_3$, and $\text{R}^{III}\text{O}_2 \cdot 7\text{WO}_3$, i.e. as salts of the hypothetical acid $\text{H}_6\text{W}_7\text{O}_{24}$, wherein 6H are replaced by 6R^1 , 3R^{II} , or 2R^{III} ; if the less simple formula (5:12) is adopted, the paratungstates of monovalent and divalent metals are regarded as salts of the hypothetical acid $\text{H}_{10}\text{W}_{12}\text{O}_{41}$ ($=12\text{WO}_3 \cdot 5\text{H}_2\text{O}$), wherein 10H are replaced by 10R^1 or 5R^{II} ; paratungstates of R^{III} must be represented in this scheme by the complicated formula $\text{R}^{III}_2\text{O} \cdot (\text{W}_{12}\text{O}_{41})_5$. In the paratungstates which have been best examined $\text{R}^1 = \text{NH}_4$, Li, Hg, K, Ag, and Na; $\text{R}^{II} = \text{Ba}$, Cd, Ca, Co, Cu, Pb, Mg, Mn, Ni, Sr, and Zn; and $\text{R}^{III} = \text{Al}$ and Cr. The simpler formulæ are employed in the descriptions of the individual salts.

Aluminium paratungstate $\text{Al}_2\text{W}_7\text{O}_{24} \cdot 9\text{H}_2\text{O}$. A flocculent pp., drying to gum-like lumps; obtained by adding $(\text{NH}_4)_2\text{W}_7\text{O}_{24}\text{Aq}$ to a solution of a salt of Al (Lotz, *A.* 83, 65; Anthon, *J. pr.* 8, 399; 9, 337).

Ammonium paratungstate $(\text{NH}_4)_6\text{W}_7\text{O}_{24} \cdot 6\text{H}_2\text{O}$. Obtained by dissolving $\text{WO}_3 \cdot \text{H}_2\text{O}$ in NH_4Aq and crystallising at the ordinary, or a little above the ordinary, temperature (Lotz, *A.* 91, 55). Crystallises in white, rhombic needles (Marignac, *A. Ch.* [3] 69, 25; Kerndt, *J. pr.* 41, 190); also in rhombic tablets (M., *l.c.*); and is, therefore, dimorphous. Solubility = 2.8 to 4.5 at 15° – 22° ; when the solution is boiled the very soluble meta-salt $(\text{NH}_4)_2\text{W}_7\text{O}_{13}$ is formed. Loses 3.9 p.c. H_2O at 100° ; when heated to redness the blue oxide of W remains mixed with compounds containing N (M., *l.c.*). Marignac (*l.c.*) gave the formula $(\text{NH}_4)_{10}\text{W}_{12}\text{O}_{41} \cdot 11\text{H}_2\text{O}$ to this salt; Berzelius, and Anthon (*l.c.*) gave the formula $(\text{NH}_4)_2\text{W}_7\text{O}_{24} \cdot \text{H}_2\text{O}$; and Riche (v. Marignac, *l.c.*) the formula $(\text{NH}_4)_2\text{W}_7\text{O}_{13} \cdot 5$ or $6\text{H}_2\text{O}$.

Various double salts have been isolated; with $\text{Na}_6\text{W}_7\text{O}_{24}$ (v. Knorre, *B.* 19, 821; Gibbs, *Am. J.* 236); with $\text{K}_6\text{W}_7\text{O}_{24}$ (v. Laurent, *A. Ch.* [3] 21, 59; Marignac, *A. Ch.* [3] 69, 55); with $\text{Mg}_3\text{W}_7\text{O}_{24}$ v. M. (*l.c.*), Lotz (*A.* 91, 61); with $\text{Zn}_3\text{W}_7\text{O}_{24}$ v. Lotz (*l.c.*); with $\text{Cd}_3\text{W}_7\text{O}_{24}$ v. L. (*l.c.*); with $\text{Hg}_3\text{W}_7\text{O}_{24}$ v. Anthon (*J. pr.* 8, 399; 9, 337).

Barium paratungstate $\text{Ba}_3\text{W}_7\text{O}_{24} \cdot 8\text{H}_2\text{O}$. A white pp. formed by adding $(\text{NH}_4)_6\text{W}_7\text{O}_{24}\text{Aq}$ to excess of BaCl_2Aq , washing and drying over H_2SO_4 (Lotz, *A.* 93, 60; cf. Knorre, *B.* 18, 327; 19, 820). Forms a double salt with $\text{Na}_6\text{W}_7\text{O}_{24}$ (Scheibler, *J. pr.* 83, 314).

Cadmium paratungstate $\text{Cd}_3\text{W}_7\text{O}_{24} \cdot 16\text{H}_2\text{O}$; white needles, obtained by adding $\text{Na}_6\text{W}_7\text{O}_{24}\text{Aq}$ to excess of solution of a salt of Cd (Gonzalez, *J. pr.* [2] 36, 44).

Calcium paratungstate $\text{Ca}_3\text{W}_7\text{O}_{24} \cdot 18\text{H}_2\text{O}$; a crystalline pp. formed by ppg. excess of CaCl_2Aq by $\text{Na}_6\text{W}_7\text{O}_{24}\text{Aq}$, and drying in the air (Knorre, *B.* 18, 328). Forms a double salt with $\text{Na}_6\text{W}_7\text{O}_{24}$ (Gonzalez, *l.c.*).

Chromium paratungstate $\text{Cr}_2\text{W}_7\text{O}_{24} \cdot 9\text{H}_2\text{O}$; a grey powder, obtained by heating CrCl_3 with $(\text{NH}_4)_6\text{W}_7\text{O}_{24}$; insoluble in water, but dissolves in CrCl_3Aq (Lotz, *A.* 91, 66).

Cobalt paratungstate $\text{Co}_3\text{W}_7\text{O}_{24} \cdot 25\text{H}_2\text{O}$ (Gonzalez, *l.c.*); forms a double salt with $\text{Na}_6\text{W}_7\text{O}_{24}$ (G., *l.c.*).

Copper paratungstate $\text{Cu}_3\text{W}_7\text{O}_{24} \cdot 19\text{H}_2\text{O}$; a pale-green pp. formed by adding $\text{Na}_6\text{W}_7\text{O}_{24}\text{Aq}$ to

excess of CuSO_4Aq (Knorre, B. 19, 826; v. also Gonzalez, *J. pr.* [2] 36, 44). Forms a *double salt* with $\text{Na}_2\text{W}_2\text{O}_{21}$ (K., l.c.).

Lead paratungstate $\text{Pb}_2\text{W}_2\text{O}_{21}$; a white pp. formed by adding $(\text{NH}_4)_2\text{W}_2\text{O}_{21}\text{Aq}$ to $\text{Pb}(\text{NO}_3)_2\text{Aq}$ (Lotz, A. 91, 49). Forms a *double salt* with $\text{Na}_2\text{W}_2\text{O}_{21}$ (Gonzalez, l.c.).

Lithium paratungstate $\text{Li}_3\text{W}_2\text{O}_{21} \cdot 19\text{H}_2\text{O}$. Large prisms, unchanged in air; obtained by boiling the proper quantities of WO_3 and Li_2CO_3 in water, and allowing to crystallise (Scheibler, *J. pr.* 83, 321).

Magnesium paratungstate $\text{Mg}_3\text{W}_2\text{O}_{21} \cdot 24\text{H}_2\text{O}$; obtained by ppn. (Knorre, B. 19, 824). Forms a *double salt* with $\text{Na}_2\text{W}_2\text{O}_{21}$ (K., l.c.).

Manganese paratungstate $\text{Mn}_3\text{W}_2\text{O}_{21} \cdot 34\text{H}_2\text{O}$ (Gonzalez, *J. pr.* [2] 36, 44). Forms a *double salt* with $\text{Na}_2\text{W}_2\text{O}_{21}$ (K., l.c.).

Nickel paratungstate $\text{Ni}_3\text{W}_2\text{O}_{21} \cdot 14\text{H}_2\text{O}$ (Anthon, *J. pr.* 9, 344).

Potassium paratungstate $\text{K}_6\text{W}_2\text{O}_{21} \cdot 6\text{H}_2\text{O}$ (Marignac, A. Ch. [3] 69, 33, gave the formula $\text{K}_{10}\text{W}_{12}\text{O}_{41} \cdot 11\text{H}_2\text{O}$). Prepared by saturating hot KOH Aq with $\text{WO}_3 \cdot x\text{H}_2\text{O}$, and allowing to cool; by boiling K_2WO_4 with H_2O ; or by fusing *wolframite* with $\frac{2}{3}$ of its weight of K_2CO_3 , boiling the product with water, saturating the aqueous solution with CO_2 , and crystallising (M., l.c.). White rhombic crystals, isomorphous with the NH_4 salt (M., l.c.). Decomposed, by melting, to K_2WO_4 and $5\text{K}_2\text{O} \cdot 14\text{WO}_3$, without forming any meta- salt (Knorre, *J. pr.* [2] 27, 91). Solubility = 2.15 cold water, 6.6 boiling water.

Various *hydrates* have been obtained (v. Zettnow, P. 130, 241; cf. Lefort, A. Ch. [5] 9, 93; 15, 321; 17, 470; 25, 200). Forms *double salts* with $\text{Na}_2\text{W}_2\text{O}_{21}$ (v. Marignac, A. Ch. [3] 69, 55; Laurent, A. Ch. [3] 21, 54).

Silver paratungstate $\text{Ag}_3\text{W}_2\text{O}_{21}$; a yellow, crystalline pp. formed by adding $\text{Na}_2\text{W}_2\text{O}_{21}\text{Aq}$ to excess of AgNO_3Aq (Gonzalez, *J. pr.* [2] 36, 44).

Sodium paratungstate $\text{Na}_2\text{W}_2\text{O}_{21} \cdot 16\text{H}_2\text{O}$. This formula is given by Scheibler (*J. pr.* 83, 285); the formula $\text{Na}_{10}\text{W}_{12}\text{O}_{41}$ is given by Laurent (l.c.), Marignac (l.c.), and by Friedheim a. Meyer, (*Zeit. f. anorg. Chemie*, 1, 81). Prepared by saturating hot NaOH Aq , or $\text{Na}_2\text{CO}_3\text{Aq}$, with $\text{WO}_3 \cdot x\text{H}_2\text{O}$ and evaporating to the crystallising point; also by passing CO_2 into $\text{Na}_2\text{WO}_4\text{Aq}$ until the reaction is only faintly alkaline. Large, well-formed, white, triclinic crystals (Scheibler, l.c.; Marignac, A. Ch. [3] 69, 39). Effloresces in air; loses c. $\frac{2}{3}$ of its H_2O over H_2SO_4 ; is dehydrated without decomposition at 300° (S., l.c.); heated to dull redness leaves a residue, insoluble in water, containing more than 5WO_3 to Na_2O (M., l.c.; also Knorre, *J. pr.* [2] 27, 71). Melts above dull redness, giving Na_2WO_4 and $\text{Na}_2\text{W}_2\text{O}_{21}$ (meta- salt). Heated with water to 150° gives much meta- salt (K., l.c.). Solubility 8 to 9 at 35° to 40° ; for the salts obtainable from an aqueous solution v. M. (l.c.), and also K. (B. 18, 2362). By boiling a solution with Na_2CO_3 transformation to Na_2WO_4 is complete (v. Schmidt, *Am.* 8, 16). A *hydrate* with $21\text{H}_2\text{O}$ has been obtained (M., l.c.). Forms *double salts* with $\text{Sr}_2\text{W}_2\text{O}_{21}$ (Gonzalez, *J. pr.* [2] 36, 44), and with $\text{Zn}_2\text{W}_2\text{O}_{21}$ (Knorre, B. 19, 823).

Strontium paratungstate $\text{Sr}_2\text{W}_2\text{O}_{21} \cdot 8\text{H}_2\text{O}$ (Knorre, B. 18, 827).

Zinc paratungstate $\text{Zn}_2\text{W}_2\text{O}_{21} \cdot x\text{H}_2\text{O}$ (Gonzalez, *J. pr.* [2] 36, 44).

METATUNGSTATES OR TETRATUNGSTATES, $\text{R}^{10}\text{O} \cdot 4\text{WO}_3$ or $\text{R}^{11}\text{W}_4\text{O}_{41}$. Salts of the acid $\text{H}_2\text{W}_4\text{O}_{41}$ (v. METATUNGSTIC ACIDS, p. 802). The metatungstates may be obtained by causing metatungstic acid $\text{H}_2\text{W}_4\text{O}_{41} \cdot x\text{H}_2\text{O}$ (v. p. 802) to interact with carbonates, chlorides, or nitrates; also by the reaction of a weak acid ($\text{H}_3\text{PO}_4\text{Aq}$ is the best) with orthotungstates, the acid being added as long as the pp. of $\text{WO}_3 \cdot x\text{H}_2\text{O}$ which is at first formed re-dissolves; also from the alkali salts by double decomposition, or better from the Ba salt by interacting with sulphates; the alkali metatungstates are prepared by boiling solutions of the ortho-tungstates for some time with $\text{WO}_3 \cdot x\text{H}_2\text{O}$.

Most of the metatungstates are very soluble in water and are crystallisable from aqueous solutions; aqueous solutions are not ppd. by acids in the cold, but pps. are obtained after long standing or boiling. Metatungstates are changed to ortho- salts by excess of alkali; when strongly heated, orthotungstates are formed. Solutions of metatungstates are not ppd. by H_2S ; $(\text{NH}_4)_2\text{SAq}$ gives a blue pp.; pps. are not obtained with salts of the heavy metals except Pb and Hg^1 ; $\text{K}_2\text{FeCy}_2\text{Aq}$ does not form a pp.

Ammonium metatungstate

$(\text{NH}_4)_6\text{W}_4\text{O}_{41} \cdot 8\text{H}_2\text{O}$. This formula is given by Scheibler (*J. pr.* 83, 303); more complicated formulæ are given by Margueritte (A. Ch. [3] 17, 477), Laurent (A. Ch. [3] 21, 62), and Lotz (A. 91, 55). Obtained by boiling the para- salt $(\text{NH}_4)_6\text{W}_4\text{O}_{41} \cdot x\text{H}_2\text{O}$ with $\text{WO}_3 \cdot \text{H}_2\text{O}$ (Margueritte, A. Ch. [3] 17, 477); also by boiling the para- salt with a little HNO_3Aq (Laurent, A. Ch. [3] 21, 62); also by heating the dry para- salt to 250° – 300° (Scheibler, *J. pr.* 83, 304; cf. Persoz, A. Ch. [4] 1, 101; and Marignac, A. Ch. [4] 3, 71). White octahedra; effloresces in air; loses $7\text{H}_2\text{O}$ at 100° . Solubility in cold water = 120 (Lotz, l.c.) = 286 (Riche, A. Ch. [3] 50, 45). The solution is optically refractive. Insoluble in alcohol or ether. Forms a *double salt* with NH_4NO_3 (Marignac, A. Ch. [3] 69, 61).

Barium metatungstate $\text{BaW}_4\text{O}_{41} \cdot 9\text{H}_2\text{O}$. Obtained by adding BaCl_2Aq to a hot conc. solution of $\text{Na}_2\text{W}_4\text{O}_{41}$, acidified by HCl Aq (Scheibler, *J. pr.* 83, 304). Crystallises in large, white, tetragonal octahedra; S.G. 4.293 at 14° ; loses $6\text{H}_2\text{O}$ at 100° ; easily soluble in hot water, decomposed by much cold water to WO_3 and $\text{BaW}_4\text{O}_{41} \cdot 6\text{H}_2\text{O}$, which dissolve again on heating.

Cadmium metatungstate $\text{CdW}_4\text{O}_{41} \cdot 10\text{H}_2\text{O}$. Lustrous, white octahedra; unchanged in air; obtained by decomposing $\text{BaW}_4\text{O}_{41}\text{Aq}$ by CdSO_4Aq (S., l.c., p. 273).

Calcium metatungstate $\text{CaW}_4\text{O}_{41} \cdot 10\text{H}_2\text{O}$. Quadric octahedra; obtained by dissolving CaCO_3 in $\text{H}_2\text{W}_4\text{O}_{41}\text{Aq}$ and crystallising (S., l.c., p. 314).

Cobalt metatungstate $\text{CoW}_4\text{O}_{41} \cdot 9\text{H}_2\text{O}$ (S., l.c. p. 317).

Copper metatungstate $\text{CuW}_4\text{O}_{41} \cdot 11\text{H}_2\text{O}$ (S., l.c. p. 317).

Magnesium metatungstate $\text{MgW}_4\text{O}_{41} \cdot 8\text{H}_2\text{O}$ (S., l.c.).

Manganese metatungstate $\text{MnW}_4\text{O}_{41} \cdot 10\text{H}_2\text{O}$ (S., l.c. p. 273).

Mercurous metatungstate $\text{Hg}_2\text{W}_2\text{O}_{11} \cdot 25\text{H}_2\text{O}$. Obtained, as a white pp., by adding HgNO_3Aq to solution of $\text{H}_2\text{W}_2\text{O}_{11}$ or a meta-salt (S., l.c., p. 319).

Nickel metatungstate $\text{NiW}_2\text{O}_{11} \cdot 8\text{H}_2\text{O}$ (S., l.c., p. 273).

Potassium metatungstate $\text{K}_2\text{W}_2\text{O}_{11} \cdot 8\text{H}_2\text{O}$. Lustrous octahedra; obtained by boiling $\text{K}_2\text{W}_2\text{O}_{11}\text{Aq}$ with $\text{WO}_3 \cdot x\text{H}_2\text{O}$; very soluble in hot water, considerably less soluble in cold water (S., l.c., p. 303). A pentahydrate was obtained by Marignac (A. Ch. [4] 3, 71).

Silver metatungstate $\text{Ag}_2\text{W}_2\text{O}_{11}$. Obtained, as a crystalline crust, by adding AgNO_3Aq to $\text{Na}_2\text{W}_2\text{O}_{11}\text{Aq}$, evaporating, separating from Ag_2WO_4 , and evaporating again (S., l.c. p. 318).

Sodium metatungstate $\text{Na}_2\text{W}_2\text{O}_{11} \cdot 10\text{H}_2\text{O}$. Obtained by boiling $\text{Na}_2\text{W}_2\text{O}_{11}\text{Aq}$ with $\text{WO}_3 \cdot x\text{H}_2\text{O}$ and allowing to evaporate; white, lustrous octahedra; S.G. 3.8647 at 13° ; very soluble in hot, but less in cold, water (S., l.c. p. 303).

Strontium metatungstate $\text{SrW}_2\text{O}_{11} \cdot 8\text{H}_2\text{O}$ (S., l.c. p. 314).

Zinc metatungstate $\text{ZnW}_2\text{O}_{11} \cdot 10\text{H}_2\text{O}$ (S., l.c. p. 273).

TUNGSTATES OTHER THAN ORTHO-, PARA-, AND META-SALTS.

Ditungstates. Salts of the form $\text{R}_2\text{O} \cdot 2\text{WO}_3 = \text{R}_2\text{W}_2\text{O}_7$. Salts of K and Na of this composition were said by Lefort (A. Ch. [5] 17, 470) to be formed by neutralising cold solutions of K_2WO_4 and Na_2WO_4 by acetic acid; Knorre (J. pr. [2] 27, 83) obtained only metatungstates, $\text{R}_2\text{W}_2\text{O}_{11}$, by this method.

Two to five tungstates. The existence of salts of the class $2\text{R}_2\text{O} \cdot 5\text{WO}_3 = \text{R}_4\text{W}_5\text{O}_{17}$, is doubtful. Marignac obtained a salt to which he gave the formula $\text{Na}_4\text{W}_5\text{O}_{17} \cdot 11\text{H}_2\text{O}$ along with the para-salt $\text{Na}_4\text{W}_5\text{O}_{16} \cdot 16\text{H}_2\text{O}$ (A. Ch. [3] 69, 50). The same salt seems to have been obtained by Lefort (l.c.; cf. Forcher a. Gibbs, J. 1880. 341) by adding acetic acid and alkali to $\text{Na}_2\text{WO}_4\text{Aq}$ and allowing to stand for some time (cf. also Schmidt, Am. 8, 16).

Three to eight tungstates. A salt $(\text{NH}_4)_3\text{W}_8\text{O}_{27} \cdot 8\text{H}_2\text{O} = 3(\text{NH}_4)_2\text{O} \cdot 8\text{WO}_3 \cdot 8\text{H}_2\text{O}$ seems to have been prepared by Marignac (A. Ch. [3] 69, 61).

Tritungstates $\text{R}^{10}\text{O} \cdot 3\text{WO}_3 = \text{R}^{10}\text{W}_3\text{O}_{19}$. Lefort (A. Ch. [5] 17, 470) prepared a salt to which he gave the formula $\text{Na}_4\text{W}_3\text{O}_{19} \cdot 6\text{H}_2\text{O}$, by pouring a boiling solution of $\text{Na}_2\text{W}_2\text{O}_{11} \cdot 6\text{H}_2\text{O}$ (obtained by adding acetic acid to $\text{Na}_2\text{WO}_4\text{Aq}$ until the liquid shows an acid reaction) into boiling acetic acid, allowing to cool, separating the lower syrupy layer, and crystallising it. A corresponding salt $\text{K}_4\text{W}_3\text{O}_{19} \cdot 2\text{H}_2\text{O}$ was obtained by a similar method; and a series of tritungstates was prepared by mixing equivalent quantities of the Na salt and metallic acetates, in solution, and adding alcohol. L. describes the tritungstates as easily decomposing in aqueous solutions to di- and tetra-salts. The following salts were formed by L.: — $\text{BaW}_3\text{O}_{19} \cdot 4\text{H}_2\text{O}$; $\text{CdW}_3\text{O}_{19} \cdot 4\text{H}_2\text{O}$; $\text{CaW}_3\text{O}_{19} \cdot 6\text{H}_2\text{O}$; $\text{CoW}_3\text{O}_{19} \cdot 4\text{H}_2\text{O}$; $\text{FeW}_3\text{O}_{19} \cdot 4\text{H}_2\text{O}$; $\text{PbW}_3\text{O}_{19} \cdot 2\text{H}_2\text{O}$; $\text{MgW}_3\text{O}_{19} \cdot 4\text{H}_2\text{O}$; $\text{MnW}_3\text{O}_{19} \cdot 5\text{H}_2\text{O}$; $\text{NiW}_3\text{O}_{19} \cdot 4\text{H}_2\text{O}$; $\text{K}_4\text{W}_3\text{O}_{19} \cdot 2\text{H}_2\text{O}$; $\text{Na}_4\text{W}_3\text{O}_{19} \cdot 4\text{H}_2\text{O}$; $\text{SrW}_3\text{O}_{19} \cdot 5\text{H}_2\text{O}$. Knorre's experiments led him to regard Lefort's tritungstates as mixtures (J. pr. [2] 27, 83).

Penta- and octo-tungstates. Salts

of K and Na of the composition $\text{R}_4\text{W}_5\text{O}_{17}$, and $\text{R}_4\text{W}_8\text{O}_{27}$, are said to have been isolated, the former by fusing mixtures of R_2WO_4 and WO_3 , the latter by fusing $\text{R}_4\text{W}_5\text{O}_{17}$ with R_2WO_4 (Knorre, J. pr. [2] 27, 81, 91).

A few tungstates that do not find places in any of the foregoing classes have been described by different observers (v. especially Lefort, A. Ch. [5] 9, 93; 15, 324; 17, 470; 25, 200; also Scheibler, J. pr. 83, 237; Gonzalez, J. pr. [2] 86, 44; Knorre, J. pr. [2] 27, 93; Lotz, A. 91, 49; Feit, B. 21, 133; Cleve, Bl. [2] 43, 170; Högborn, Bl. [2] 42, 2).

PERTUNGSTATES. By boiling a solution of the paratungstate $\text{Na}_4\text{W}_5\text{O}_{16} \cdot 16\text{H}_2\text{O}$ with $\text{H}_2\text{O}_2\text{Aq}$, and then evaporating *in vacuo*, Péchard (C. R. 112, 1060) obtained small white crystals of a salt to which he gave the formula $\text{Na}_4\text{O} \cdot \text{W}_5\text{O}_{16} \cdot 2\text{H}_2\text{O} = \text{NaWO}_4 \cdot \text{H}_2\text{O}$; and by treating $(\text{NH}_4)_3\text{W}_8\text{O}_{27} \cdot 8\text{H}_2\text{O}$ in a similar way he isolated the corresponding NH_4 pertungstate. According to P. these salts are decomposed by alkalis with evolution of O ; solutions of them set free I from KIAg , and react with HClAq , giving off Cl .

TUNGSTEN BRONZES. Bright-coloured, lustrous, metal-like, crystalline solids, obtained by the action of reducers—such as H , coal-gas, Sn , or Fe —on tungstates of Li , K , or Na ; also by the electrolysis of these tungstates when molten. The composition of these compounds, which are known as bronzes and are used as pigments, is represented by the formula $\text{M}_x(\text{WO}_3)_y$, where $\text{M} = \text{Li}$, K , or Na . The constitutions of the compounds are not known; they may be represented as compounds of tungstates with WO_3 , by the general formula $x\text{M}_2\text{O}_3 \cdot y\text{WO}_3 \cdot z\text{WO}_3$; they may also be represented as compounds of M_2O with a radicle composed of W and O in a ratio greater than $\text{W}:2\text{O}$ and less than $\text{W}:3\text{O}$ —that is, as compounds of M_2O with oxides intermediate between WO_2 and WO_3 . The tungsten bronzes are insoluble in most acids, also in alkali solutions.

Sodium tungsten bronzes. These compounds are formed by the interaction of Na tungstates and H (Wöhler, P. 2, 350), Sn (Wright, A. 79, 221), coal-gas (Schnitzler, D. P. J. 211, 484), Zn or Fe (Zettnow, P. 130, 261), or by electrolysis Na tungstates (Scheibler, J. pr. 83, 321). According to Philipp (B. 15, 499), the different processes yield the same bronze if the same tungstate is used, and the more WO_3 there is in the tungstate employed the richer in WO_3 is the bronze produced. All the compounds are insoluble in acids or alkalis; they dissolve in NaClO_4Aq ; heated with NH_3Aq and AgNO_3Aq they give Ag and WO_3 (cf. P. a. Schwebel, B. 12, 2234; 15, 500; Knorre, J. pr. [2] 27, 51). These compounds are slowly oxidised to tungstates by heating to redness in air (K., l.c.). Philipp (l.c.) gave S.G. of all the sodium bronzes as 7.2 to 7.3 at 16° to 18° .

Purple-red bronze $\text{Na}_4\text{W}_5\text{O}_{16} = \text{Na}_2\text{O} \cdot 2\text{WO}_3 \cdot \text{WO}_3 = \text{Na}_2\text{O} \cdot \text{W}_5\text{O}_{16} = \text{Na}_2\text{WO}_4 \cdot \text{W}_2\text{O}_5$. Prepared by fusing for c. half an hour a mixture of 10.9 g. Na_2CO_3 , 71.7 g. WO_3 , and 20 g. tinfoil, and boiling successively with H_2O , NaOH Aq , and HCl Aq . Red cubes; the powder transmits green light when suspended in water (P., l.c.).

Red-yellow bronze $\text{Na}_4\text{W}_8\text{O}_{27} = 2\text{Na}_2\text{O} \cdot 5\text{WO}_3 \cdot 2\text{WO}_3 = 2\text{Na}_2\text{O} \cdot \text{W}_8\text{O}_{27}$. Prepared by

melting 60 to 80 g. of a mixture of Na_2WO_4 and WO_3 in the ratio $2\text{Na}_2\text{WO}_4:\text{WO}_3$, adding 80 g. tinfoil, and keeping molten for 1 to 2 hours. Red-yellow cubic; the powder is brownish yellow, and transmits blue light when suspended in water (P., *l.c.*).

Gold-yellow bronze $\text{Na}_2\text{W}_2\text{O}_{11} = 5\text{Na}_2\text{O} \cdot 7\text{WO}_3 \cdot 5\text{WO}_2 = 5\text{Na}_2\text{O} \cdot \text{W}_{12}\text{O}_{41}$. Prepared by heating $\text{Na}_2\text{W}_2\text{O}_{11}$ to dull redness in H, powdering and again heating in H, and then boiling with H_2O , HClAq , and $\text{Na}_2\text{CO}_3\text{Aq}$ successively. Golden yellow, crystalline powder (P., *l.c.*; cf. Wöhler, P. 2, 350; Wright, A. 79, 221).

Blue bronze $\text{Na}_2\text{W}_2\text{O}_{11} = \text{Na}_2\text{O} \cdot 4\text{WO}_3 \cdot \text{WO}_2 = \text{Na}_2\text{O} \cdot \text{W}_{10}\text{O}_{39}$. Prepared by fusing Na_2WO_4 with more than 2WO_3 , and adding tinfoil; also by melting $\text{Na}_2\text{W}_2\text{O}_{11}$ (paratungstate) and electrolyzing with 6 Zn-Pt elements (P., *l.c.*; Scheibler, J. pr. 83, 321; cf. Knorre, J. pr. [2] 27, 49; and Zettnow, P. 130, 261). Dark-blue cubes, with a red sheen; S.G. 7.28 at 17°.

Potassium tungsten bronzes. The compound $\text{K}_2\text{W}_2\text{O}_{11} = \text{K}_2\text{O} \cdot 3\text{WO}_3 \cdot \text{WO}_2 = \text{K}_2\text{O} \cdot \text{W}_{10}\text{O}_{39}$ seems to be the only one of this class that has been isolated. Prepared by fusing K_2WO_4 with WO_3 and adding tinfoil; also by fusing K_2CO_3 with from 3WO_3 to 4WO_3 , and reducing by H or coal gas; also by electrolyzing a molten mixture of K_2WO_4 and WO_3 . Reddish-violet prisms, giving a blue powder, which transmits greenish light when suspended in water; S.G. c. 7.1 (Laurent, A. Ch. [2] 67, 219; Zettnow, P. 130, 262; Knorre, J. pr. [2] 27, 63).

Lithium tungsten bronzes. A compound of this class, probably $\text{Li}_2\text{W}_2\text{O}_{11}$, is obtained by fusing $\text{Li}_2\text{W}_2\text{O}_{11}$ (paratungstate) with tin. Dark-blue crystals (Scheibler, J. pr. 83, 321; Knorre, *l.c.*, p. 69; Feit, B. 21, 133).

A **potassium sodium bronze** and a **potassium lithium bronze** have been obtained (Knorre, *l.c.* p. 66; Feit, *l.c.*).

COMPLEX TUNGSTIC ACIDS AND SALTS. Tungstic oxide WO_3 combines with several anhydrides, e.g. B_2O_3 , P_2O_5 , As_2O_3 , SiO_2 , &c., and water, to form acidic compounds, and also with these anhydrides and basic oxides to form salt-like compounds; the whole of these compounds are usually grouped together as *complex tungstic acids* and *complex tungstates*, and they are divided into such classes as *arsenotungstates*, *phosphotungstates*, &c.

ANTIMONOTUNGSTIC ACIDS AND SALTS. According to Lefort (A. Ch. [5] 17, 487), the compounds $\text{Sb}_2\text{O}_3 \cdot 5\text{WO}_3 \cdot 4\text{H}_2\text{O}$ and $\text{Sb}_2\text{O}_3 \cdot 6\text{WO}_3 \cdot 8\text{H}_2\text{O}$ are formed by dissolving tartar emetic in $\text{Na}_2\text{O} \cdot 3\text{WO}_3\text{Aq}$ and $\text{Na}_2\text{O} \cdot 2\text{WO}_3\text{Aq}$ respectively. Gibbs (Am. 7, 392) obtained $4\text{BaO} \cdot 6\text{Sb}_2\text{O}_3 \cdot 22\text{WO}_3 \cdot 86\text{H}_2\text{O}$ and $6\text{K}_2\text{O} \cdot 4\text{Sb}_2\text{O}_3 \cdot 12\text{WO}_3 \cdot 25\text{H}_2\text{O}$.

ARSENOTUNGSTIC ACIDS AND SALTS. Compounds of the form $\text{As}_2\text{O}_3 \cdot 16\text{WO}_3 \cdot x\text{H}_2\text{O}$ have been obtained by Kehrman (A. 245, 45; cf. Fremery, B. 17, 296); and series of compounds of As_2O_3 with WO_3 and basic oxides (Na_2O , K_2O , BaO , &c.), in which the ratio of $\text{As}_2\text{O}_3:\text{WO}_3$ is 1:6 and 1:8, have been described by Gibbs (Am. 7, 818). Compounds of WO_3 with As_2O_3 and bases, and also with As_2O_3 and As_2O_5 and bases, and finally with As_2O_3 and P_2O_5 and bases, are described by Gibbs (*l.c.*).

BOROTUNGSTIC ACIDS AND SALTS. Two com-

pounds of B_2O_3 and WO_3 have probably been isolated, in which the ratios of the oxides are 1:14 and 1:9 respectively; compounds of each of these with bases are known (Klein, A. Ch. [5] 28, 350).

BOROTUNGSTIC ACID AND SALTS

$\text{B}_2\text{O}_3 \cdot 14\text{WO}_3 \cdot x\text{H}_2\text{O}$. A solution containing B_2O_3 and WO_3 in the ratio 1:14 is obtained by boiling $\text{Na}_2\text{WO}_4\text{Aq}$ with $\text{B}_2\text{O}_3\text{Aq}$, 4ppg. by HgNO_3Aq , decomposing the pp. by H_2S , and expelling H_2S from the filtrate by warming (for details v. K., *l.c.*). Compounds of the form $x\text{MO} \cdot \text{B}_2\text{O}_3 \cdot 14\text{WO}_3 \cdot y\text{H}_2\text{O}$ have been formed, where $x = 2, 3$, and 4, and M is Ba, K, Ag, Na, and Sr.

Tungstoboric acid and salts. The compound $\text{B}_2\text{O}_3 \cdot 9\text{WO}_3 \cdot x\text{H}_2\text{O}$, usually known as tungstoboric acid, is obtained in yellowish octahedra by evaporating the solution of borotungstic acid. A considerable number of compounds of bases with B_2O_3 and WO_3 , in the ratio $\text{B}_2\text{O}_3:9\text{WO}_3$, has been obtained; most of them are of the form $2\text{MO} \cdot \text{B}_2\text{O}_3 \cdot 9\text{WO}_3 \cdot x\text{H}_2\text{O}$, M = $(\text{NH}_4)_2$, Ba, Cd, Ca, Co, Cu, Li, Mg, Mn, Hg, Ni, K, Na, Tl; a few salts $2\text{M}_2\text{O} \cdot \text{B}_2\text{O}_3 \cdot 9\text{WO}_3 \cdot x\text{H}_2\text{O}$ (M = Al or Cr) are also described by Klein (*l.c.*).

FLUOTUNGSTATES AND ALLIED COMPOUNDS; v. TUNGSTOXYFLUORIDES (p. 799).

IODOTUNGSTATES. Blomstrand (J. pr. 40, 327) described a compound $2\text{K}_2\text{O} \cdot \text{I}_2\text{O}_5 \cdot 2\text{WO}_3 \cdot 3\text{H}_2\text{O}$, obtained by adding the calculated quantity of HIO_3 to $\text{K}_2\text{WO}_4\text{Aq}$.

PHOSPHOTUNGSTIC ACIDS AND SALTS. The oxides WO_3 and P_2O_5 combine in several proportions, in presence of H_2O , to form complex acids which contain large quantities of WO_3 relatively to the P_2O_5 . A great many compounds are known containing WO_3 and P_2O_5 combined with basic oxides.

Phosphotungstic acids. Compounds of the form $\text{P}_2\text{O}_5 \cdot x\text{WO}_3 \cdot y\text{H}_2\text{O}$; compounds wherein $x = 24, 21, 20, 16$, and 12 seem to have been isolated. The existence of these compounds was made known by Scheibler (B. 5, 802); they have been investigated chiefly by Gibbs (Am. 2, 217, 281; 4, 377; 5, 861, 391; 7, 813, 392; Péchard, C. R. 109, 801; 110, 754; and Kehrman, B. 20, 1805, 1811; 24, 2326; 25, 1966; A. 245, 45; Zeit. f. anorg. Chemie, 1, 428; also Drechsel, B. 20, 1452; and Brandhorst a. Kraut, A. 249, 373). The phosphotungstic acids are obtained by boiling $\text{H}_3\text{PO}_4\text{Aq}$ with $\text{H}_2\text{W}_2\text{O}_{11} \cdot x\text{H}_2\text{O}$ (meta-acid); by decomposing the mercurous salts by HClAq ; and by boiling $\text{Na}_2\text{W}_2\text{O}_{11} \cdot x\text{H}_2\text{O}$ (para-salt) with $\text{Na}_2\text{HPO}_4\text{Aq}$, decomposing by HClAq , and dissolving the acids thus formed in ether. The phosphotungstic acids are unchanged in solutions in dilute acids; these solutions are scarcely acted on by H_2S , and very slightly by zinc; they give phosphates and tungstates when boiled with alkalis; characteristic pps. are produced with alkaloïds, urea, albumen, &c.

Phosphododecitungstic acid and salts $\text{P}_2\text{O}_5 \cdot 24\text{WO}_3 \cdot x\text{H}_2\text{O}$ and $y\text{MO} \cdot \text{P}_2\text{O}_5 \cdot 24\text{WO}_3 \cdot x\text{H}_2\text{O}$. The acid is obtained by evaporating a solution of H_3PO_4 and $\text{H}_2\text{W}_2\text{O}_{11} \cdot x\text{H}_2\text{O}$ in the proper proportion (Péchard, *l.c.*); by boiling a solution of tungstate and phosphate of Na, in the ratio $24\text{Na}_2\text{WO}_4:2\text{Na}_2\text{HPO}_4$, acidulating with HNO_3Aq , ppg. by HgNO_3Aq , decomposing the Hg salt by HClAq , filtering, and evaporating *in vacuo*

(Gibbs, *Am.* 2, 217); by boiling $\text{H}_3\text{PO}_4\text{aq}$ with BaWO_4 in the proper proportion, decomposing by a small excess of $\text{H}_2\text{SO}_4\text{aq}$, removing H_2SO_4 by BaOaq , filtering, and evaporating (Sprenger, *J. pr.* [2] 22, 418). The acid crystallises in white, regular octahedra, or cubes. The value for x in the formula $\text{P}_2\text{O}_5 \cdot 24\text{WO}_3 \cdot x\text{H}_2\text{O}$ varies according to different observers, from 40 to 53, 59, and 61. The salts $y\text{MO} \cdot \text{P}_2\text{O}_5 \cdot 24\text{WO}_3 \cdot x\text{H}_2\text{O}$ are obtained by mixing tungstates (normal or para- salts) with $\text{H}_3\text{PO}_4\text{aq}$ or a phosphate, and decomposing by slight excess of HClaq , HNO_3aq , or $\text{H}_2\text{SO}_4\text{aq}$; in most cases the salts ppt. as fine, white powders; in some cases it is advisable to evaporate to dryness, extract with alcohol and ether, and evaporate. The salts have been described by Gibbs (*l.c.*); Kehrman (*Zeit. f. anorg. Chemie*, 1, 430); K. a. Freinkel (*B.* 24, 2327); Sprenger (*J. pr.* [2] 122, 418); and Brandhorst a. Kraut (*A.* 249, 373). Salts have been obtained wherein $\text{MO} = (\text{NH}_4)_2\text{O}$, BaO , CuO , K_2O , Ag_2O , and Na_2O , and $y = 1, 2$, and 3.

Phospholutedungstic acid and salts. $\text{P}_2\text{O}_5 \cdot 16\text{WO}_3 \cdot x\text{H}_2\text{O}$ and $y\text{MO} \cdot \text{P}_2\text{O}_5 \cdot 16\text{WO}_3 \cdot x\text{H}_2\text{O}$. The acid is obtained by boiling $\text{Na}_2\text{WO}_4\text{aq}$ with $\text{H}_2\text{PO}_4\text{aq}$, acidulating with HNO_3aq , adding NH_4Cl and boiling, crystallising the pp. from NH_4Claq , evaporating the NH_4 salt thus produced with *aqua regia*, and crystallising the acid so formed from water (for details v. K., *l.c.*). To an acid obtained by decomposing the K salt by $\text{H}_2\text{SiF}_6\text{aq}$, or the Ag salt by HClaq , K. gives the formula $\text{P}_2\text{O}_5 \cdot 18\text{WO}_3 \cdot x\text{H}_2\text{O}$; and he says that the salts are $y\text{MO} \cdot \text{P}_2\text{O}_5 \cdot 18\text{WO}_3 \cdot x\text{H}_2\text{O}$. The acid forms citron-yellow, six-sided tablets; it melts by the heat of the hand, and is very soluble in water. According to K. (*B.* 20, 1805; *A.* 245, 45), salts of this series are obtained by boiling any phosphotungstates with excess of $\text{H}_2\text{PO}_4\text{aq}$ in presence of an alkali salt. It is probable that two series of salts exist—one with 16WO_3 , and another with 18WO_3 (cf. Gibbs, *l.c.*; and Péchard, *l.c.*). Salts have been obtained wherein $\text{MO} = (\text{NH}_4)_2\text{O}$, BaO , CaO , CuO , PbO , and K_2O , and $y = 1, 3, 4$, and 6.

Other phosphotungstic acids and salts.

I. Salts of the form $y\text{MO} \cdot \text{P}_2\text{O}_5 \cdot 22\text{WO}_3 \cdot x\text{H}_2\text{O}$ have been obtained, wherein $\text{MO} = (\text{NH}_4)_2\text{O}$, BaO , and K_2O , and $y = 2, 3, 4$, and 7 (v. K. a. F., *B.* 24, 2327; 25, 1966; K., *Zeit. f. anorg. Chemie*, 1, 435; Sprenger, *l.c.*; Gibbs, *l.c.*).

II. An acid of the form $\text{P}_2\text{O}_5 \cdot 21\text{WO}_3 \cdot x\text{H}_2\text{O}$, and salts $y\text{MO} \cdot \text{P}_2\text{O}_5 \cdot 21\text{WO}_3 \cdot x\text{H}_2\text{O}$, where $\text{MO} = (\text{NH}_4)_2\text{O}$, K_2O , and Ag_2O and $y = 3$, have been isolated (K. a. F., *l.c.*; K., *l.c.*).

III. The acid $\text{P}_2\text{O}_5 \cdot 20\text{WO}_3 \cdot x\text{H}_2\text{O}$ and a salt $6\text{BaO} \cdot \text{P}_2\text{O}_5 \cdot 20\text{WO}_3 \cdot x\text{H}_2\text{O}$ were obtained by Péchard (*l.c.*) and Gibbs (*l.c.*).

IV. For the acid $\text{P}_2\text{O}_5 \cdot 12\text{WO}_3 \cdot x\text{H}_2\text{O}$ and the salts $y\text{MO} \cdot \text{P}_2\text{O}_5 \cdot 12\text{WO}_3 \cdot x\text{H}_2\text{O}$, where $\text{MO} = (\text{NH}_4)_2\text{O}$, BaO , CaO , CuO , PbO , Li_2O , MgO , Hg_2O , K_2O , Ag_2O , Na_2O , TiO_2 , and ZnO , v. Péchard (*C. R.* 110, 754).

V. A few salts of the form $y\text{MO} \cdot \text{P}_2\text{O}_5 \cdot 7\text{WO}_3 \cdot x\text{H}_2\text{O}$ have been obtained ($\text{MO} = (\text{NH}_4)_2\text{O}$, BaO , CaO , Hg_2O , Na_2O ; y doubtful) (Gibbs, *l.c.*; K., *l.c.*).

VI. Compounds of alkali phosphates with WO_3 , and with phosphoric acids and WO_3 , have been isolated; also compounds of alkalis with H_3PO_4 and WO_3 , and with H_2PO_4 and WO_3 ,

are described by Gibbs (*Am.* 5, 861; 7, 818, 892).

PLATINITUNGSTATES, v. this vol., p. 283.

SILICOTUNGSTIC ACIDS AND SALTS. Three compounds of SiO_2 with WO_3 and H_2O , which react as acids, have been isolated, and many compounds of bases with SiO_2 and WO_3 have been obtained (Marignac, *A. Ch.* [4] 8, 5).

Silicoduoodecitungstic acid, and salts $\text{SiO}_2 \cdot 12\text{WO}_3 \cdot x\text{H}_2\text{O}$; as most of the salts contain $4\text{M}_2\text{O}$ (or 2MO) the acid is usually written $4\text{H}_2\text{O} \cdot \text{SiO}_2 \cdot 12\text{WO}_3 \cdot x\text{H}_2\text{O}$ ($= \text{H}_4\text{SiW}_{12}\text{O}_{42} \cdot x\text{H}_2\text{O}$). According to Drechsel (*B.* 20, 1452), the acid is most easily obtained by dissolving Na_2WO_4 in boiling water, nearly neutralising with HNO_3aq , dissolving the crystals that separate in cold water, boiling this solution with gelatinous $\text{SiO}_2 \cdot x\text{H}_2\text{O}$ until HClaq ceases to give a pp., filtering, evaporating, adding a large excess of $\text{H}_2\text{SO}_4\text{aq}$, extracting with ether, separating the lowest layer and evaporating (for details v. D., *l.c.*). Large, colourless, dimetric octahedra (with $x = 29$); loses $25\text{H}_2\text{O}$ at 100° , and all H_2O at 850° . Very soluble in water and alkali solutions. Most of the salts of this acid have the composition $4\text{M}_2\text{O} \cdot \text{SiO}_2 \cdot 12\text{WO}_3 \cdot x\text{H}_2\text{O}$, or $2\text{MO} \cdot \text{SiO}_2 \cdot 12\text{WO}_3 \cdot x\text{H}_2\text{O}$; $\text{M}_2\text{O} = (\text{NH}_4)_2\text{O}$, Hg_2O , K_2O , Ag_2O , Na_2O ; $\text{MO} = \text{BaO}$, CaO , MgO ; x varies from 7 to 28 (Marignac, *l.c.*).

Tungstosilicic acid, and salts. This name is generally given to an acid containing SiO_2 and WO_3 in the same ratio (1:12) as silicoduoodecitungstic acid. The formula of the acid is generally written $4\text{H}_2\text{O} \cdot \text{SiO}_2 \cdot 12\text{WO}_3 \cdot 20\text{H}_2\text{O}$. The acid is obtained by evaporating a solution of silicoduoodecitungstic acid to dryness, taking up with water, filtering from separated SiO_2 , evaporating to a syrup, and allowing to crystallise. Forms short, white, triclinic prisms; melts under 100° , giving off $16\text{H}_2\text{O}$ and again solidifying. The salts of this acid are obtained by dissolving carbonates in a solution of the acid, and evaporating; they are more soluble and less easily crystallised than the salts of the duoodeci-acid; the salts are of the forms

- (1) $2\text{MO}(4\text{M}_2\text{O}) \cdot \text{SiO}_2 \cdot 12\text{WO}_3 \cdot x\text{H}_2\text{O}$, where $\text{M} = \text{Ca}$, or $\text{M}_2 = \text{K}_2$;
- (2) $2\text{M}_2\text{O} \cdot 2\text{H}_2\text{O} \cdot \text{SiO}_2 \cdot 12\text{WO}_3 \cdot x\text{H}_2\text{O}$, where $\text{M}_2 = \text{K}_2$ or Na_2 ; some more complex salts have also been isolated (Marignac, *l.c.*).

Silico-decitungstic acid, and salts. The acid $4\text{H}_2\text{O} \cdot \text{SiO}_2 \cdot 10\text{WO}_3 \cdot x\text{H}_2\text{O}$ (x probably = 3) is obtained by decomposing the Ag salt by HClaq , filtering, and evaporating *in vacuo*; the Ag salt is prepared by adding AgNO_3aq to the NH_4 salt which is obtained by boiling an acid tungstate of NH_4 with $\text{SiO}_2 \cdot x\text{H}_2\text{O}$, filtering, and evaporating. The acid forms a clear, yellowish, glassy solid, which does not wholly dissolve in water; loses $8\text{H}_2\text{O}$ at 100° ; on boiling with water most of the SiO_2 separates, and the filtrate contains tungstosilicic acid. A few salts have been obtained; they are difficult to purify from silicotungstates and tungstosilicates (Marignac, *l.c.*).

STANNIPHOSPHOTUNGSTATES. Gibbs (*Am.* 7, 892) obtained the salt $2(\text{NH}_4)_2\text{O} \cdot \text{P}_2\text{O}_5 \cdot 2\text{SnO}_2 \cdot 22\text{WO}_3 \cdot 15\text{E}_2\text{O}$ by the reaction of $\text{SnCl}_2 \cdot 2\text{NH}_4\text{Cl}$ and $2\text{Na}_2\text{O} \cdot \text{P}_2\text{O}_5 \cdot 24\text{WO}_3 \cdot x\text{H}_2\text{O}$.

TUNGSTEN OXIDES. Two acids, $4\text{H}_2\text{O}.\text{TiO}_2.12\text{WO}_3.x\text{H}_2\text{O}$ and $4\text{H}_2\text{O}.\text{TiO}_2.10\text{WO}_3.x\text{H}_2\text{O}$, are described by Lecaraine (*v. Klein, Bl.* [2] 36, 17).

VANADOTUNGSTIC ACIDS AND SALTS. Several compounds of WO_3 with V_2O_5 and H_2O have been described by Gibbs (*Am.* 4, 377; 5, 361, 391) and Rosenheim (*A.* 251, 197); they belong to the forms $\text{V}_2\text{O}_5.10\text{WO}_3.x\text{H}_2\text{O}$, $\text{V}_2\text{O}_5.18\text{WO}_3.x\text{H}_2\text{O}$, and $\text{V}_2\text{O}_5.4\text{WO}_3.x\text{H}_2\text{O}$. Compounds of these with $\gamma\text{M}_2\text{O}$ and γMO are also described; and a great variety of compounds coming under the general formula $m\text{MO}.n\text{V}_2\text{O}_5.p\text{WO}_3.x\text{H}_2\text{O}$ have been obtained (*cf.* Friedheim, *B.* 23, 1505; and Rothenbach, *B.* 23, 3050).

Tungsten, oxybromides of. Two oxybromides, WO_2Br and WOBr_2 , are formed by the reaction of Br on WO_3 , and in other ways. The formula WOBr , is very probably molecular, from the analogy of WOCl .

TUNGSTEN DIOXYDIBROMIDE WO_2Br_2 . Obtained by heating WO_3 in a stream of Br vapour, also by passing vapour of WBr_5 over heated WO_3 (Roscoe, *C. N.* 25, 73); also by heating WS_2 or ϵ mixture of WO_3 and C in Br (Borck, *J. pr.* 54, 254). Red, transparent, prismatic crystals; appearing black when hot, and giving a yellow powder. Volatilised at red heat with partial decomposition to WO_3 and WOBr_2 .

TUNGSTEN OXYTETRABROMIDE WOBr_4 . Obtained by passing Br vapour over a heated mixture of equal parts of WO_3 and W, and cautiously distilling from less volatile WO_2Br_2 (Roscoe, *C. N.* 25, 73). Also formed by passing Br mixed with some O over heated W, or by heating a mixture of WO_3 and C in Br vapour (Blomstrand, *J. pr.* 82, 430). Brownish black, lustrous, crystalline needles; melts at 277° and boils at 327° . Heated in moist air gives WO_3 and HBr , and is decomposed to the same products by water.

Tungsten, oxychlorides of. Two oxychlorides, WO_2Cl_2 and WOCl_4 , are formed by heating W in Cl mixed with some O, and in other reactions.

TUNGSTEN DIOXYDICHLORIDE WO_2Cl_2 . Obtained by heating WO_3 in a stream of Cl, and subliming (Roscoe, *C. N.* 25, 63); also by passing CO_2 over a mixture of WO_3 and CaCl_2 heated to redness (Schultze, *J. pr.* [2] 21, 439). Also formed, along with WOCl_4 , by heating W in Cl mixed with O; by heating WO_3 and C in Cl; by heating WO_3 in CCl_4 (Watts a. Bell, *C. J.* 33, 442); and by heating WO_3 with PCl_5 (Schiff, *A.* 197, 185; *cf.* TUNGSTEN TRIOXIDE, *Reactions*, No. 10, p. 801). Yellow, four-sided tablets; sublimes without melting at $c. 266^\circ$, with partial decomposition to WO_3 and WOCl_4 . Not decomposed in moist air, nor by cold water (*R., l.c.*). Heated in dry NH_3 gives off NH_4Cl and leaves WO_3 (Rideal, *C. J.* 55, 43); in this reaction WO_2Cl_2 behaves like CrO_2Cl_2 (*R., C. J.* 49, 367). According to Smith a. Shinn (*Zeit. f. anorg. Chemie*, 4, 881), a black compound $\text{W}_2\text{O}_3\text{N}_2\text{H}_2$ is formed by heating WO_2Cl_2 in dry NH_3 .

TUNGSTEN OXYTETRACHLORIDE WOCl_4 . Mol. w. 841.04. Formed by heating W in Cl containing a little O; also by passing Cl over a hot mixture of WC and C; by heating WO_3 in CCl_4 (Watts a. Bell, *C. J.* 33, 442); by heating WCl_5 or WCl_6 in O and Cl; by heating WCl_5 with

$\text{H}_2\text{C}_2\text{O}_4$; and by heating WO_3Cl_2 . Prepared by passing vapour of WCl_5 over heated WO_3 in a current of Cl (Roscoe, *C. N.* 25, 63). Also by heating WO_3 and PCl_5 in the ratio $\text{WO}_3:\text{PCl}_5$ or $\text{WO}_3:2\text{PCl}_5$, distilling off POCl_3 and the small quantities of WCl_5 and WCl_6 that are formed, washing the reddish residue with a little cold CS_2 (to remove WCl_5), then dissolving in a larger quantity of warm CS_2 , evaporating, and carefully heating the residue in a stream of CO_2 , whereby the more volatile WOCl_4 is separated from WO_3Cl_2 (Schiff, *A.* 197, 185).

WOCl_4 forms ruby-red, transparent needles; melts at 210.4° , and volatilises at 227.5° , forming a yellow vapour (*R., l.c.*). V.D. 170.2 to 175.8 at 350° , 171.5 at 440° (*R., l.c.*; *cf.* Debray, *C. R.* 60, 820). Exposure to air produces a crust of yellow WO_3Cl_2 . Heated in NH_3 probably gives W_2N_2 (Rideal, *C. J.* 55, 43). Decomposed by water, with a hissing sound, to WO_3 and HClAq (Roscoe, *l.c.*).

Tungsten, oxyfluorides of. No compound of W with O and F has been isolated, but compounds are known which may be regarded as containing WO_2F_2 . These compounds, $\text{WO}_2\text{F}_2.2\text{MF}$ and $\text{WO}_2\text{F}_2.\text{MF}$, and also a compound $\text{WO}_2\text{F}_2.2\text{KF}$, are described under TUNGSTEN OXYFLUORIDES (p. 799).

Tungsten, phosphides of. By heating W in vapour of P, a dark-grey powder was obtained by Wöhler a. Wright (*A.* 79, 244), to which they gave the composition W_3P_4 . By heating a mixture of WO_3 and P_2O_5 in a graphite crucible, W. a. W. (*l.c.*) obtained large, dark-grey, lustrous, six-sided prisms; S.G. 5.207; insoluble in acids, including *aqua regia*, soluble in a molten mixture of Na_2CO_3 and NaNO_3 ; unchanged by heating in air, but burns brilliantly in O. From an estimation of the P, W. a. W. gave the formula W_3P_4 .

Tungsten, salts of. No salts have been isolated by replacing the H of oxyacids by W. Except the halides, the only salts of W that are known are those wherein W forms part of the negative radicle.

Tungsten, selenides of. By saturating a solution of Na_2WO_4 with H_2Se , and then adding dilute $\text{H}_2\text{SO}_4\text{Aq}$, Uelsmann (*A.* 116, 125) obtained a black pp., to which he gave the formula WSe_2 (one estimation of W is given); by heating this in a tube a grey solid was obtained, said by U. to be WSe_2 (no analyses). WSe_2 is said to be easily soluble in solutions of alkalis, alkali sulphides, or alkali selenides.

Tungsten, sulphides of. Two compounds of W and S are known, WS_2 and WS_3 ; the latter is acidic, forming salts M_2WS_3 . The V.D. of neither has been determined.

TUNGSTEN DISULPHIDE WS_2 . Obtained by heating WO_3 to whiteness in vapour of S or in H_2S (Berzelius); also by heating W and S; also by heating WO_3 with 6 pts. HgS out of contact with air (Borck, *J. pr.* 54, 254). According to Carnot (*Bl.* [2] 32, 164), WS_2 is usually formed when a compound of W is heated in a stream of dry H_2S (*v.* also von Uslar, *A.* 94, 256; Corleis, *A.* 232, 262). A dark-grey, graphite-like, lustrous, crystalline powder (*v.* Riche, *A. Ch.* [3] 50, 26). Is said to decompose steam at a full red heat; reduced to W by very long continued heating in H.

TUNGSTEN TRISULPHIDE WS_3 . Obtained by fusing powdered *wolframite* with 2 pts. C, 3 pts. S, and 3 pts. Na_2CO_3 , dissolving in water, decomposing the Na_2WS_4 thus produced by $HClAq$, washing the pp. completely out of contact with O, and drying at 100° (von Usler, *A.* 94, 256; Corleis, *A.* 232, 264). A black powder; slightly soluble in water, more soluble on boiling, probably with partial decomposition. Soluble in alkali sulphide solutions, forming thio-salts (v. TUNGSTEN, THIO-ACIDS AND SALTS OF, *infra*). By adding to Na_2WS_4 a little more $HClAq$ than was needed to combine with the Na, Winsinger (*Bl.* [2] 49, 452) obtained a colloidal form of WS_3 .

Tungsten, sulpho-acids and salts of, v. next article.

Tungsten, thio-acids and salts of. By saturating $(NH_4)_2WO_4$ and K_2WO_4 with H_2S , Berzelius obtained $(NH_4)_2WS_4$ and K_2WS_4 (*P.* 8, 267); these salts were more fully examined by Corleis (*A.* 232, 258), who also obtained Na_2WS_4 , and also some thio-oxy-tungstates. All the thio-tungstates that have been isolated are ortho-salts, i.e. salts of H_2WS_4 . Very dilute solutions of thiotungstates can be titrated with IAq in presence of $KHCO_3$ (*C.* *l.c.*).

Ammonium thiotungstate $(NH_4)_2WS_4$. Obtained by passing H_2S for four or five hours into a solution of 10 g. $WO_3 \cdot H_2O$ in 100 c.c. NH_4Aq S.G. .94, + 20 c.c. water, allowing to stand for some hours in a closed vessel, and washing the crystals that separate with alcohol and ether. Forms orange-yellow prisms, isomorphous with $(NH_4)_2MoS_4$; very easily decomposed in moist air; easily soluble in water, slightly soluble in alcohol. Heated in CO_2 gives WS_2 (*B.* *l.c.*; *C.* *l.c.*).

Ammonium dithio-oxy-tungstate $(NH_4)_2WS_2O_2$. Obtained by passing H_2S into a solution of 10 g. $WO_3 \cdot H_2O$ in 40 c.c. NH_4Aq S.G. .90, + 10 c.c. water, until the liquid becomes turbid, and washing the crystals that form with alcohol and ether. Forms yellow, prismatic crystals. When dry, the salt is unchanged in air. Decomposed by re-crystallising from water, giving paratungstate $(NH_4)_4W_7O_{22} \cdot 6H_2O$ (*C.* *l.c.*).

Potassium thiotungstate K_2WS_4 . Obtained by warming $(NH_4)_2WS_4$ with $KHSa$, adding alcohol, and crystallising from conc. $KHSa$. Forms yellow, prismatic needles; easily soluble in water. By continued boiling with $KHSa$ paratungstate is formed, $K_4W_7O_{22} \cdot 6H_2O$ (*C.* *l.c.*). Forms a double salt with KNO_3 , with the composition $K_2WS_4 \cdot KNO_3$ (*B.* *l.c.*).

Potassium trithio-oxy-tungstate $K_2WS_3O \cdot H_2O$. Obtained in citron-yellow, quadratic tablets, by passing H_2S for three or four hours into a solution of 10 g. K_2WO_4 in 10 c.c. water, and evaporating *in vacuo*, or precipitating by alcohol (*C.* *l.c.*).

Potassium monothio-oxy-tungstat. $K_2WSO_3 \cdot H_2O$. Obtained, in almost colourless, very hygroscopic, crystalline masses, by passing H_2S into a solution of 10 g. K_2WO_4 in 5 c.c. water until the liquid is turbid, filtering, adding 4 to 5 vols. alcohol, separating the under layer of liquid, allowing to crystallise, and washing with alcohol and ether (*C.* *l.c.*).

Sodium thiotungstate Na_2WS_4 . Obtained,

but not pure, by Corleis (*l.c.*), by decomposing $(NH_4)_2WS_4$ by $NaHSa$.

Tungsten, thiochloride of. By heating W to redness with S_2Cl_2 , Smith & Oberholtzer (*Zeit. f. anorg. Chemie*, 5, 63) obtained a red, crystalline sublimate, unstable in air, probably $W_2S_3Cl_4$.

TUNGSTEN BRONZES v. under TUNGSTEN OXYACIDS, p. 806.

TUNGSTIC ACIDS v. TUNGSTEN OXYACIDS, p. 802; also TUNGSTEN THIO-ACIDS, *supra*.

TUNGSTOXYFLUORIDES v. under TUNGSTEN FLUORIDES, p. 799.

TUNGSTEN, ORGANIC COMPOUNDS OF. Tungsten, heated with MeI at 240° , forms WMe_4I_4 [110°], which crystallises in tables, and is converted by Ag_2O into WMe_4O , which dissolves in acids (Riche, *C. R.* 42, 203; Jahours, *A.* 122, 70).

TUNICIN v. ANIMAL CELLULOSE, vol. i. p. 718.

TURMERIC. The root of *Amomum Curcuma*. It contains curcumin (*q. v.*) and turmerol.

TURMERIC ACID $C_{11}H_7O_6$. [35°]. A product of oxidation of turmerol by cold $KMnO_4$ (Jackson & Menke, *Am.* 6, 77). Needles, sl. sol. water, v. sol. alcohol.— $CaA_2 \cdot 3aq$. S. (of CaA_2) 1.28 at 16° . White needles.— AgA' .

TURMEROL $C_{11}H_{12}O_2$ (?). (193° – 198° at 60 mm.). S.G. 1.2902. [α]_D = 33.5° . An oil occurring in turmeric. Distils with decomposition at 285° – 290° (Jackson & Menke, *Am.* 4, 368; 6, 77). Dextrorotatory. Does not combine with $NaHSO_4$. $KMnO_4$ oxidises it to acetic, terephthalic, turmeric, and apoturmeric acids. PCl_5 forms $C_{11}H_7Cl$, which is also got by heating turmerol with conc. $HClAq$ at 160° . Sodium forms $C_{11}H_7ONa$, whence isobutyl iodide forms oily $C_{11}H_7OC_4H_9$.

Apoturmeric acid $C_8H_8(CO_2H)_2$ (?). [221°]. Woolly mass, sol. boiling water.

TURPENTINE. Semi-fluid resins exuding from coniferous trees. They consist of resin dissolved in oil of turpentine. On distillation oil of turpentine passes over and colophony remains behind. The various oils of turpentine are described under TERPENES. The chief constituent of colophony is abietic anhydride (v. ABIETIC ACID AND SYLVIC ACID). On oxidation by dilute HNO_3 , colophony yields isophthalic, trimellitic, and terebic acids (Schroder, *A.* 172, 93). On the products of distillation of colophony v. RESINS.

TURPETHIN $C_{12}H_{16}O_4$. [$c. 188^\circ$]. Occurs in the root of *Convolvulus Turpethum* (*Ipomoea Turpethum*) (Boutron-Charlard, *J. Ph.* 8, 131; Spirgatis, *J. pr.* 92, 97; *A.* 189, 41). Purgative yellowish-brown resin, v. sol. alcohol, insol. ether (difference from jalapin). Conc. H_2SO_4 forms a red solution. Boiling alkalis convert it into turpethic acid. Boiling dilute mineral acids yield glucose (3 mols.) and turpetholic acid (1 mol.).

Turpethic acid $C_{12}H_{16}O_4$. Amorphous yellowish mass, v. sol. water. Split up by boiling $HClAq$ into glucose and turpetholic acid.— BaA'' .— BaH_2A'' (dried at 100°).

Turpetholic acid $C_{12}H_{16}O_5$. [$c. 88^\circ$]. Minute needles (from dilute alcohol), sl. sol. ether.— NaA' (dried at 100°).— BaA' . Amorphous.— AgA' . Amorphous pp.

Ethyl ether EtA. [79°]. Plates.

TYLOPHORIN 3. An alkaloid in *Tylophora asthmatica* (Hoopér, *Ph.* [3] 21, 617). Crystalline, sol. water, sol. alcohol and ether.

TYPE METAL. An alloy of 15-20 parts Sb with a. 70 parts Pl. and 10 to 15 parts Sn; *v.* LEAD ALLOYS, vol. iii. p. 124.

TYPES. The object of classification is to put together like things, and to put apart things that are unlike. A perfect system of chemical classification would place side by side those elements and compounds that are chemically similar, and it would also indicate the relations that exist between all the elements and all the compounds. Inasmuch as the object of chemistry is the study of the connections between composition and properties, and between changes of composition and changes of properties, a complete scheme of chemical classification must indicate the relations of the substances classified, both as regards composition and also as regards properties. To connect composition with properties necessitates a thorough knowledge of both, and this knowledge can be gained only by comparing one substance with other substances. But, because of the large amount of detailed investigation that is required before the chemical properties of an element or a compound are known, chemists have often forgotten the larger issues of their labours, and have busied themselves rather with the examination of individual bodies than with the comparative study of many bodies. And, because of the imperfection of chemical knowledge at any time, those who have attempted the classification of chemical substances have generally paid chief attention either to the composition or to the properties of the substances to be classified. Hence systems of classification have sometimes prevailed that were founded chiefly on similarities of composition, and at other times classificatory schemes have been in vogue that rested mainly on similarities of properties. But there has always been a desire, and generally an effort, to classify on the bases of composition and properties. To classify satisfactorily demands the recognition of a simple class-mark, which shall also be clear, definable, and invariably applicable. It is probably correct to say that none of the larger classes of chemical compounds has a class-mark of this description. Hence the main difficulty in chemical classification. Take, for instance, the great class of acids. What is the class-mark? What must be known about the composition of a compound before it is put into the class of acids? There is no single and sufficient class-mark to be gained by studying the compositions of acids. What, then, about the properties of acids? Here, too, no simple, definable, and applicable property has been found which serves to distinguish acids from all other compounds. Acids, it is usually said, are compounds containing replaceable hydrogen. But the expression replaceable hydrogen has not been, and cannot be, exactly defined. Hence, all that can be done is to set up an ideal or typical acid, and to place in the class acids those compounds which fairly closely approach this type as regards both properties and composition. And as with acids so with other classes of compounds. A classification by means of types becomes inevitable in such a science as chemistry,

but a typical classification cannot be final in any exact science.

Lavoisier's system of classification rested on oxygen; compounds were regarded as formed by the union of oxygen with other elements or groups of elements; the non-oxygenated part of a compound was called by Lavoisier the *rest* or *radicle*; compounds of oxygen with certain radicles were bases, compounds with other radicles were acids, and salts were formed by the union of bases with acids. Lavoisier used the term *radicle* to include elements and groups of elements.

‘J’ai déjà fait observer, que dans le règne minéral presque tous les radicaux oxidables et acidifiables étaient simples; que dans le règne végétal au contraire, et surtout dans le règne animal, il n’en existait presque pas qui ne fussent composés au moins de deux substances, d’hydrogène et de carbone; que souvent l’azote et le phosphore s’y réunissaient, et qu’il en résultait des radicaux à quatre bases.’—*Traité élémentaire de Chimie*, [1793], p. 251.

About twenty-four years after Lavoisier made this statement Berzelius repeated it.

‘Nachdem wir den Unterschied zwischen den Producten der organischen und der unorganischen Natur, und die verschiedene Art und Weise wie ihre entfernteren Bestandtheile untereinander verbunden sind, näher kennen gelernt, haben wir gefunden, dass dieser Unterschied eigentlich darin besteht, dass in der unorganischen Natur alle oxydirten Körper *eine einfaches Radical* haben, während dagegen alle organischen Substanzen aus *Oxyden mit zusammenge-setztem Radical* bestehen.’—*Lehrbuch der Chemie*, 2. Aufl. (Stockholm, 1817), vol. i. p. 544.

Why do acids and bases unite to form salts? What is the cause of the formation of compounds by the union of radicles, either simple or compound? These questions were answered by Berzelius by appealing to the fact that the electric current very often resolves compounds into two parts, and in many cases also effects the combination of elements or groups of elements. Radicles combine, said Berzelius, because the negative electricity on one is thereby neutralised by the positive electricity on the other. Thus arose the electro-chemical conception of dualism (*v.* DUALISM, vol. ii. p. 415; *cf.* RADICLE, vol. iv. p. 893).

In 1832 Liebig and Wöhler made an exhaustive study of compounds obtained from bitter-almond oil; they showed that the relations of composition and properties of these compounds were brought together, and expressed in a consistent conception by supposing that all the compounds contained a radicle having the composition $C_7H_5O(C=12, O=16)$; this group of elements, common to all the derivatives of bitter-almond oil, they called *benzoyl*. The work of Liebig and Wöhler marked a great advance in chemical classification; it was the actual working out of the connections between composition and properties of a number of compounds, and the expression of these connections in clear and definite language. The term *radicle* became henceforth the expression of a vivifying conception. The compounds derived from bitter-almond oil had certain common properties, and they had also a common composition; they belonged to the same type. The compounds of benzoyl examined by Liebig and Wöhler included such compounds as these: $C_7H_5O.OH$, $C_7H_5O.H$, $C_7H_5O.Cl$, $C_7H_5O.CN$, $C_7H_5O.NO$. The radicle C_7H_5O is common to all; this radicle is united with H, Cl, NO , CN, or some other radicle, in the different compounds; neverthe-

less, the properties of the compounds are so similar that all are said to belong to one type. To what extent, then, it was asked, may the properties of one radicle differ from those of another before the replacement of one of these by the other carries with it a change of type? The answer generally given to this question was: If the replacing radicle is chemically similar to the radicle replaced the type will not be destroyed. In 1834 Dumas, from the study of the action of chlorine on various organic compounds, announced the *empirical laws of substitution* as follows: (1) When a compound containing hydrogen is subjected to the dehydrogenating action of chlorine, bromine, iodine, oxygen, &c., one atom of chlorine, bromine, iodine, or oxygen, is taken up for each atom of hydrogen lost by the compound. (2) The same rule applies, without modifications, when the compound contains oxygen. (3) If a hydrogenised compound contains water the hydrogen of the water is given up without replacement, and then another quantity of hydrogen is absorbed, so that the final result is a replacement of hydrogen. A year or so later Laurent propounded a *theory of substitution*, which asserted that when equivalent substitution of hydrogen by chlorine or bromine occurs the chlorine or bromine takes the place of the hydrogen, and to a certain extent plays the same part as the hydrogen, and hence the chlorinated or brominated product must be similar to the compound from which it has been prepared. Laurent's views were much opposed, for a time by Dumas himself; but they gradually prevailed, and chemists became familiarised with the notion of the replacement of such a decidedly electro-positive element as hydrogen by an element so decidedly electro-negative as chlorine, resulting in the production of a compound of the same chemical type as the original substance.

About 1839 Dumas sought to distinguish mechanical types from chemical types. Compounds formed one from the other by the replacement of a certain number of equivalents of one radicle by the same number of equivalents of another radicle, and having their radicles similarly combined, and exhibiting similar properties, were said to belong to the same *chemical type*. Compounds were said to belong to the same *mechanical type* when they were composed of equal numbers of equivalents of radicles, but differed essentially in their properties. Dumas at this time regarded the properties of compounds as conditioned more by the arrangement than by the nature of their parts. He compared compounds to planetary systems, the planets being represented by the atoms of the compounds. One atom, he said, might be replaced by another atom, or an atom by a group of atoms, without destroying the system: if the number of replacing atoms, or radicles, were the same as the number of atoms, or radicles, replaced, and the relative arrangement of all the atoms or radicles were not altered, the compounds belonged to the same type. By some such development as this the theory of types came to include the older theory of radicles.

It is evident that the terms used by Dumas and others to express the conceptions of the theory of types are vague and incapable of

exact definition. The expression 'equivalent radicles' cannot be defined, nor can an exact and invariable connotation be given to the expressions 'radicles similarly combined' and 'compounds having similar properties.' But if it had been possible to classify chemical substances in an ideally perfect way the theory of types would not have arisen. If there is to be a typical classification the language whereby that classification is expressed must be more or less vague. Whether a compound formed from another by replacing equivalents of one kind by an equal number of equivalents of another kind does or does not belong to the same type as the parent compound can be determined only by a careful study of the properties of both compounds and by a comparison of the compounds one with another. The application of the theory of types was possible only when the properties and the compositions of compounds were exhaustively compared. The theory of types produced much fruit, because it suggested and demanded much inquiry into the fundamental problem of chemistry.

In 1849 Wurtz prepared two compounds which resembled ammonia in their prominent characters. These compounds were found to have the compositions C_2H_5N and C_4H_9N respectively ($C=6$). The similarities between the properties of these compounds and ammoniated Wurtz to regard them as *substituted ammonias*, and to express this conception by the formulæ $C_2H_5.NH_2$ and $C_4H_9.NH_2$. One method by which these compounds were prepared consisted in treating methyl and ethyl bromides (C_2H_5Br and C_4H_9Br ; $C=6$) with ammonia, and then decomposing the products by potash. These reactions suggested the view that the new compounds were derived from methylic and ethylic ethers (C_2H_5O and C_4H_9O , according to the notation then used) by substituting NH_2 for O . Both views agreed in representing the new compounds as $C_2H_5.NH_2$ and $C_4H_9.NH_2$, respectively. But the properties of the compounds resembled those of ammonia; hence the view that Wurtz's compounds were derived from ammonia prevailed. This view was expressed by saying that these compounds belonged to the ammonia type, and by comparing the formula of the typical compound with the formulæ of the compounds formed after that exemplar; thus:

Type: Derivatives:

Ammonia $NH_3.H$. Methylamine $NH_2.C_2H_5$.
 Ethylamine $NH_2.C_4H_9$.

Very soon after Wurtz's preparation of methylamine and ethylamine Hofmann argued that it should be possible to substitute each of the three atoms of hydrogen in NH_3 by the radicles C_2H_5 and C_4H_9 , and so to obtain the compounds $NH(C_2H_5)_3$, $N(C_2H_5)_2$, $NH(C_4H_9)_3$, and $N(C_4H_9)_2$, ($C=6$), all which compounds ought to resemble ammonia in their properties. Hofmann fulfilled his own prophecy by preparing di- and tri-methylamine and di- and tri-ethylamine; and, basing his methods on the conception of the ammonia type, he prepared a large series of ammonia-like compounds derived from NH_3 , $2NH_3$, &c., by substituting for H various radicles composed of carbon and hydrogen. The ammonia type was thus established.

About the year 1850 Williamson studied the relations of ether to alcohol. The formula of ether was then written C_2H_5O ($C=6, O=8$), and that of alcohol $C_2H_5O_2$. Williamson heated potassium alcoholate ($C_2H_5KO_2$) with ethylic iodide (C_2H_5I), expecting to obtain ethylated alcohol ($C_2H_5(C_2H_5O_2)$); but he obtained common ether. Williamson suggested that the formula then accepted for ether should be doubled, and written $(C_2H_5)_2O_2$. He also found that by heating common alcohol with sulphuric acid, and adding methylic alcohol to the hot mixture, an ether-like compound was obtained, the simplest formula of which was C_3H_8O ($C=6, O=8$). Williamson argued that if common ether is C_2H_5O , then the ether of methylic alcohol must be C_2H_5O , and that, in the reaction of sulphuric acid with ethylic and methylic alcohols simultaneously, a mixture of these two ethers might be expected to be produced. To account for the facts he had observed Williamson proposed to double the formulae of the two ethers and to write them $(C_2H_5)_2O_2$ and $(C_2H_5)_2O_2$; and for the formula of the ether formed by the action of sulphuric acid on the two alcohols simultaneously he proposed the formula $C_2H_5(C_2H_5)_2O_2$ [$=2C_2H_5O$]. Williamson compared the relations between the alcohols and ethers with the relations between water, potash, and potassium oxide. These relations are made clearer if the formulae are expressed in terms of the atomic weights $C=12$ and $O=16$; thus:

Type:	Derivatives:
Water $H.H.O$	Alcohol $C_2H_5.H.O$
	Ether $C_2H_5.C_2H_5.O$
	Potash $K.H.O$
	Potassium oxide $K.K.O$.

Thus arose the *water type*. To this were referred such compounds as acetic acid $C_2H_3O.H.O$, anhydrous acetic acid $C_2H_3O.C_2H_3O.O$, and many others.

Gradually the greater number of compounds, both organic and inorganic, came to be referred to four fundamental types—the *hydrochloric acid type* HCl , the *water type* HHO , the *ammonia type* $NHHH$, and the *marsh gas type* $CHHHH$. To these were added so-called *condensed types* and *mixed types*; sulphuric acid, for instance, $SO_2.OH.OH$, was said to belong to the *double water type*.

Thus:

$$\begin{array}{c} H \\ H \\ H \\ H \end{array} \left\{ \begin{array}{c} O \\ O \\ O \\ O \end{array} \right. \begin{array}{c} H \\ H \\ H \\ H \end{array} \left\{ \begin{array}{c} O \\ O \\ O \\ O \end{array} \right. \text{ gives } SO_2$$

Oxamic acid $CO.NH_2.CO.OH$ was regarded by Wurtz as derived from the *water-ammonia type*.

Thus:

$$\begin{array}{c} H \\ H \\ H \\ H \end{array} \left\{ \begin{array}{c} O \\ O \\ O \\ O \end{array} \right. \begin{array}{c} H \\ H \\ H \\ H \end{array} \left\{ \begin{array}{c} O \\ O \\ O \\ O \end{array} \right. \text{ gives } C_2O_2$$

$$\begin{array}{c} H \\ H \\ H \\ H \end{array} \left\{ \begin{array}{c} O \\ O \\ O \\ O \end{array} \right. \begin{array}{c} H \\ H \\ H \\ H \end{array} \left\{ \begin{array}{c} O \\ O \\ O \\ O \end{array} \right. \text{ gives } C_2O_2$$

The great danger attending the development of the theory of types was, that careful investigations into the reactions of compounds might easily be abandoned in favour of a superficial examination of a compound, followed by a relegation of it to this or that type. The theory began by being very vague and elastic; the adoption of a few definite types rendered it more exact; but the temptation to manipulate for-

mulae on paper, and to invent condensed types and mixed types, gradually led chemists to see that the theory had done its work, and that it must give place to wider views, which should also be more accurate, regarding the connections between composition and properties.

The conception of types carried with it, from the first, more or less vague notions regarding the arrangements of the atoms in those collocations of atoms that form the reacting units of compounds; at any rate, this conception was bound up with the general conception of atomic arrangement. The reacting units of compounds that showed similar properties were thought of as composed of atoms similarly arranged. Moreover, the type was said to be maintained when an atom, or a group of atoms, in the parent compound was replaced by an equivalent number of atoms, or groups of atoms. These two conceptions, that of equivalency, and that of atomic arrangement, led gradually to the representation of the reacting unit, or molecule, of a compound as a definitely arranged group of atoms held together by actions and reactions between individual atoms; these conceptions led to the wider conception of valency, and to a system of classification based on the notion that each kind of atom is capable of directly combining with a limited, and determinable, number of other atoms. The formula given to chlorosulphonic acid, with the object of connecting the composition with the properties of this compound, and of suggesting relations between this and other compounds, may be taken as an example of the merging of the notion of types into that of valency. This acid was regarded as derived both from water and hydrochloric acid; it was supposed to belong to the mixed *water-hydrochloric acid type*. Hence the formula, $ClSO_2H$, was written thus:—

The radicle SO_2 was regarded as equivalent to $2H$; and it was said that the residues of the two parts of the mixed type, i.e. Cl and OH , were bound together by the radicle SO_2 . Again, monochlorhydrin, C_2H_4ClO , was regarded as a derivative of the triple type $HHO.HCl.HHO$, and was said to be formed by the binding together of the three residues OH, Cl, OH by the radicle C_2H_4 regarded as equivalent to $3H$. Thus:—

The moment the conceptions underlying these formulae, and formulae like these, were expressed in the language of atoms and molecules, the notion of atomic valencies was gained. The group of atoms SO_2 replaces two atoms of hydrogen, one atom in the molecule HCl and one atom in the molecule HHO ; and as the atomic group SO_2 is capable of directly combining with two atoms of hydrogen, or such a number of atoms as is equivalent to two atoms of hydrogen, this group binds together the atom Cl and the atomic group OH , and so the new molecule

$\text{SO}_2\text{OH.Cl}$ is produced. This statement contains the fundamental conception of atomic valency; it also contains the conception of types, and that of radicles.

The radicles were compared as regards their equivalency, generally in terms of hydrogen; then the elementary atoms were compared, and arranged in classes, such that all in one class were exchangeable, any number of one kind for the same number of another kind.

When the atoms had been classified in accordance with the number of atoms of hydrogen, or atoms equivalent thereto, with which each was capable of combining, the foundations had been laid of a system of classification which was more accurate than that based on the notion of types, and which at the same time included the essential characters of the typical system. The article CLASSIFICATION in the first edition of this *Dictionary* represents the stage which had then (1868) been reached in the process of fusion of the theories of radicles, types, and valency. The system of classification developed in that article is based (1) on the compositions of compounds interpreted by help of the theory of valency, and (2) on the properties of the compounds interpreted by the help of the theory of types; the study of the properties of a compound is used to determine the radicles that the compound contains, and a knowledge of the valencies of these radicles determines the form of the compound, and, taken along with the reactions of the compound, the type to which it is to be referred.

Although the introduction of the principle of atomic equivalency widened the conception of chemical types, it also tended towards a method of classification which was based on too slight a study of the bodies to be classified. A superficial examination of a compound generally sufficed to bring out some similarities between it and a well-known typical substance; the new compound was at once referred to its type; the form of the type determined the form of the compound under examination; it was then only necessary to manipulate the empirical formula by arranging the elements in groups, or radicles, and to assign to each radicle such a valency as satisfied the general rules that had been deduced from the study of a few typical compounds. The conception of types became very mechanical in its applications, so mechanical indeed that it was in danger of becoming metaphysical. New radicles were easily invented, and their valencies were deduced by *a priori* arguments. Kekulé recalled chemists to the study of properties by insisting that the properties of a compound are conditioned by the properties of the atoms which compose the molecule of the compound; and at a later date Mendeléeff made the same demand by asserting that the properties and the compositions of all compounds are periodic functions of the atomic weights of the elements.

The notion of types plays an important part in the classification of elements and compounds that has arisen from the practical examination of the meaning of Mendeléeff's periodic law. The periodic classification of the elements lays considerable stress on the study of the typical oxides, hydrides, hydroxides, &c., of each group of elements; for instance, the highest salt-forming oxide of Group I. belongs to the type R_2O ,

that of Group II. to the type R_2O_3 , and so on. But the word *type* is not used here with quite the same connotation as was given to it by the theory of types. All that is implied in statements such as those just made is, that the elements of Group I. combine with oxygen in the ratio of two atoms of element to a single atom of oxygen, that these oxides are salt-forming, and that they are characteristic of the elements of this group. The typical oxide-form of each group expresses the composition of that oxide which contains the greatest number of atoms of oxygen relatively to one atom of the group-element, and which oxide reacts either with acids or with alkalis to form corresponding salts. The oxides that belong to the typical oxide-form of a group may be acidic or basic, or some of them may be acidic and some basic; all that is asserted of their properties is that they are salt-forming. The properties of the typical oxide of any individual element are conditioned by the general character of the group, and the general character of the series, wherein the element is placed; by the special character of the element itself; and by the position of the element in the whole periodic system of classification. The term *type* is used in the nomenclature arising from the comparative study of the elements and compounds based on the periodic law with a wider, and at the same time a more exact, meaning than that which was given to it when the notion of types was made the basis of chemical classification. In the older classification the conception of types was the basis of the system; the conception was of necessity vague, and hence it was necessary sometimes to widen, and sometimes to narrow, the application of the conception. The modern system of classification is based on the relative weights of the atoms of the elements, and the conception of types plays a subsidiary part; the form of the typical oxide, or hydroxide, or other compound, is determined, as the compositions of all the compounds are determined, by the relative masses of the atoms of the elements; and the general character of the typical oxide, hydroxide, &c., of each group is determined, as the special character of each compound of each element is determined, also by the relative masses of the atoms of the elements.

The periodic classification of the elements and compounds makes use of the notion of types in another way, by applying the conception to certain elements. The elements placed in series 1 and 2, viz. H, Li, Be, B, C, N, O, and F, exhibit almost the whole range of properties of all the elements. The properties of the succeeding elements may almost be said to be but variations on the theme announced in the change from hydrogen to fluorine. These eight elements are types of all the others. In a somewhat narrower sense the element lithium summarises the range of properties shown in Group I.; beryllium summarises the range of properties shown in Group II.; boron, the properties of Group III.; carbon, the properties of Group IV.; nitrogen, the properties of Group V.; oxygen, the properties of Group VI.; and fluorine, the properties of Group VII. Each of the seven elements is the typical element of its group. Objections have been raised to this use of the term *typical*, on the ground that each

of the elements in question differs more from any member of its group than any other two members of the group differ from one another. But if an element is to summarise the properties of some ten or eleven other elements, it must differ considerably from each of these, while at the same time it resembles them all. The question of typical elements, and also that of typical oxide-forms, &c., are discussed in the article PERIODIC LAW (vol. iii. p. 808); that article should be consulted.

The older classification by types prepared the way for the wider conception of valency, which took up and utilised the permanent features of the typical arrangements of elements and compounds. The study of valency led chemists to see the importance of examining the properties of the atoms of the elements, and thus made them ready to accept the more elastic, and more exact, generalisation of the periodic law. The theory of types developed into the theory of valency, and the theory of valency has been included in the theory of the periodicity of the connection between the atomic weights of the elements and the compositions and properties of the compounds of the elements. The general conception of types remains; we are still obliged to picture to ourselves a typical acid, a typical base, a typical salt, a typical alcohol, a typical amide, and so on. But this conception is no longer the basis of chemical classification. We have gone deeper down, and laid the foundations of our system on the firmer basis of the atomic weights of the elements. M. M. P. M.

TYPHOTOXINE $C_8H_{11}NO_2$. An alkaloid obtained from pure cultures of the typhogen bacillus (Gautier, *Bl.* [2] 48, 13).

TYROSINE $C_9H_9NO_3$, i.e. $C_6H_5(OH).CH_2.CH(NH_2).CO_2H$. *p*-Oxy- α -amido-phenyl-propionic acid. Mol. w. 181. [235°]. S.G. 1.456 (Siber, B. 17, 2837). S. '04 at 20°; '65 at 100°. S. (90 p.c. alcohol) '0074 in the cold. H.F. 156,400. H.C.v. 1,070,800. H.C.p. 1,071,200 (Berthelot, A. André, *Bl.* [3] 4, 227). $[a]_D^{20} = -8^\circ$ in HClAq at 16°; -9° in KOHAq at 20° (Mauthner, *M.* 3, 343).

Occurrence.—Occurs abnormally in the liver and urine (e.g. in cases of poisoning by phosphorus (Frerichs & Städeler, *J.* 1855, 729; 1856, 702; Blendermann, *H.* 6, 242), in the cutaneous scales in pellagra (Schmetzer, *Dissert.*, Erlangen, 1862), in cochineal (De la Rue, A. 64, 35), in sprouting pumpkin seeds (Schulze & Barbieri, *J. pr.* [2] 20, 401; 32, 457), in the roots of *Stachys tuberosa* (Planta, B. 23, 1699), in dahlia bulbs (Leitgeb, C. C. 1888, 1397), in alcoholic extract of woad leaves (Schunck, C. N. 37, 223), and in beetroot molasses (Lippmann, B. 17, 2835).

Formation.—1. By potash fusion from casein (Liebig, A. 57, 127; 62, 269), globulin, leathers, hairs (Leyer & Köller, A. 83, 332), and albumen (Nencki, *J. pr.* [2] 17, 97).—2. By the action of boiling dilute H_2SO_4 on ox-horn (Hinterberger, A. 71, 72), on fibrin (Städeler, A. 111, 12; 116, 57), and on silk (Weyl, B. 21, 1529).—3. By putrefaction of yeast (A. Müller, *J. pr.* 57, 162; Béchamp, C. R. 74, 115, 184), albumen and gelatin (Jeanneret, *J. pr.* [2] 15, 853).—4. In small quantity by heating conglutin with HClAq (Siegfried, B. 24, 419).—5. From γ -amido-

phenyl-alanine and HNO_3 (Friedländer & Mähly, B. 16, 854; Erlenmeyer & Lipp, A. 219, 161).

Properties.—Stellate groups of slender silky needles (from water), insol. alcohol and ether, m. sol. NH_4Aq and $KOHAq$. Laboratory. Its solution is not pptd. by lead acetate or subacetate until NH_4Aq is added. Boiling $Hg(NO_3)_2$ containing HNO_3 turns its solution red, forming a brownish-red ppt. (R. Hoffmann, A. 87, 123; L. Meyer, A. 132, 156). After warming with conc. H_2SO_4 , diluting with water, and neutralising with $BaCO_3$, the solution is turned violet by $FeCl_3$. Tyrosine gives off less N_2 when its solutions are decomposed by $NaOH$ and Br in presence of NH_3 than when the NH_3 is absent.

Reactions.—1. At 270° it splits up into CO_2 and $C_6H_5(OH).CH_2.CH_2.NH_2$ (Schmitt & Nasse, A. 133, 211).—2. Potash-fusion forms *p*-oxybenzoic and acetic acids (Barth, A. 136, 110; Ost, *J. pr.* [2] 12, 159; Baumann, *H.* 4, 304). 3. $KClO_3$ and $HClAq$ form tetra-chloro-quinone.—4. By putrefactive fermentation it is converted into hydro-*p*-coumaric acid, and finally into *p*-cresol and phenol (Weyl, B. 12, 1450).—5. $HIAq$ and P at 150° from NH_3 and *p*-oxy-phenyl-propionic acid (Hüfner, *Z.* [2] 4, 391; 6, 113). Conc. $HClAq$ and $HBrAq$ at 240° have no action.—6. Conc. H_2SO_4 (4 pts.) at 100° forms crystalline $C_8H_9(SO_3H)NO_3$, v. sl. sol. cold water, which also occurs in a hydrated amorphous form (containing 2aq). H yields $(NH_4)HA'aq$, $Ba(HA'')_2 4aq$, and $Ca(HA''')_2 5aq$ (Städeler, A. 116, 57). $BaC_8H_9NO_3 3aq$ is obtained from the product of the action of H_2SO_4 (10 pts.) on tyrosine (1 pt.).—7. $MeOH$, potash, and MeI yield crystalline $C_8H_9NIO_3K$, sol. water, decomposed by warm $KOHAq$ into NMe , and the methyl derivative of *p*-coumaric acid (Körner & Menozzi, G. 11, 550).—8. Potassium cyanate added to boiling water containing tyrosine forms tyrosine-hydantoic acid $C_8H_9(OH).CH_2.CH(NH.CO.NH_2).CO_2H$ crystallising from water in needles, insol. ether (Jaffé, *H.* 7, 810). This body begins to melt at 155°, being decomposed above 170°. It gives a red colour and ppt. on warming with Millon's reagent. It forms $KA'aq$, crystallising from alcohol-benzene.—9. Tyrosine administered to a dog appears in the urine as tyrosine-hydantoin $C_8H_9(OH).CH_2.CH \begin{smallmatrix} NH.CO \\ CO.NH \end{smallmatrix}$ [275°–280°], which crystallises from water in needles, and is decomposed by heating in sealed tubes with baryta-water into CO_2 , ammonia and tyrosine. Other products found in the urine of a rabbit after a dose of tyrosine are hydro-*p*-coumaric and *p*-oxy-phenyl-acetic acids and phenols (Blendermann, *H.* 6, 251).

Salts.— $Na_2C_8H_9NO_3$. — $CaC_8H_9NO_3$. — $BaC_8H_9NO_3 2aq$. Prisms, more sol. cold than hot water. — $Cu(C_8H_9NO_3)_2$. S. '08 in the cold; '4 at 100°. Got by adding $Cu(OH)_2$ to a boiling solution of tyrosine (Hofmeister, A. 189, 6). Insol. alcohol. Deposits black cupric oxide on boiling with water. — $C_8H_9NO_3(HgO)_2 2aq$. — $C_8H_9NO_3(HgO)_2 aq$. — $C_8H_9NO_3(HgO)_2 aq$ (Vintschgau, *J.* 1869, 985). — $Ag_2C_8H_9NO_3 aq$: amorphous ppt. — $AgC_8H_9NO_3 aq$: crystalline powder. — $B'HCl 2aq$: needles, decomposed by water. — $B'ELpCl_3$ (Gintl, *Z.* [2] 5, 704). — $B'H_2SO_4$. Slender needles, not coloured by $FeCl_3$.

Di-bromo-tyrosine $C_9H_7Br_2NO_2$, 2aq. S. 46 at 16°; 4 at 100°. Formed from dry tyrosine and Br vapour (Gorup-Besanez, *A.* 125, 281). Needles or tables (from water), sl. sol. alcohol. $Ag_2C_9H_7Br_2NO_2$, 2aq. — $B'HCl$ 1½aq. — $B'HB$. — $B'_2H_2SO_4$. Prisms, sol. water and alcohol.

Nitro-tyrosine $C_9H_9N_2O_5$, i.e. $C_9H_9(NO_2)NO_3$. Formed from tyrosine (1 pt.), water (4 pts.), and nitric acid (4 pts. of S.G. 1.3) in the cold (Strecker, *A.* 73, 70; Städeler, *A.* 116, 77). Pale-yellow needles, sl. sol. cold water. — Salts: $Ba(C_9H_7N_2O_5)_2$ (dried at 100°). Blood-red amorphous mass. — $Ag_2C_9H_7N_2O_5$, aq. orange pp. changing to a red powder. — $B'HCl$ 1½aq. Tufts of lemon-yellow needles. — $B'HNO_3$. S. 20.

Lemon-yellow needles. — B'_2LSO_4 . Yellow needles or granules.

Di-nitro-tyrosine $C_9H_7(N_2O_5)_2$, NO_2 . [115°]. Formed by warming nitro-tyrosine with dilute HNO_3 . Golden plates (from water). — Salts: $CaC_9H_7N_2O_5$, 8aq. Golden six-sided tables. — $BaC_9H_7N_2O_5$, 2aq. Ruby-red prisms with yellow reflex, exploding when heated.

Reference. — AMIDO-TYROSINE.

TYROTUXICON. A poisonous substance formed in milk, containing the butyric acid ferment, which has stood for some days. Occurs also sometimes in cheese (Vaughan, *Ph.* [3] 18, 479; *H.* 10, 146). When its alcoholic solution is mixed with $PtCl_4$ and evaporated violent explosion takes place.

U

ULEXINE $C_{22}H_{28}N_4O_2$. [151°]. An alkaloid in the seeds of common furze (*Ulex europaeus*) (Gerrard & Symons, *Ph.* [3] 17, 101, 229; 19, 1029; 20, 978, 1017). Deliquescent crystals, v. sol. chloroform, insol. ether. Poison, paralyzing respiration (Bradford, *J. Physiol.* 8, 79). Possibly identical with cytisine. — $B'HCl$. Deliquescent. — $B'HPtCl_6$. — $B'2HAcCl$.

ULTRAMARINE. The blue-coloured material contained in *lapis-lazuli*. Until 1828 ultramarine was obtained by powdering and washing *lapis-lazuli*; but since that year it has been manufactured by heating to bright redness mixtures of Al silicate (*china clay*), Na_2CO_3 (carbonated soda ash), S, and charcoal, and washing, powdering, drying, and sifting the product. (For details of the manufacture v. *DICTIONARY OF APPLIED CHEMISTRY*, vol. iii. p. 891.) The constituent elements of ultramarine are Al, Na, Si, S, and O. Treated with HCl aq, ultramarine gives off H_2S ; the solution contains $NaCl$, $AlCl_3$, and SiO_2 , and the residue consists of SiO_2 , S, and some Al_2O_3 ; these reactions point to ultramarine being a compound of silicates and polysulphides. Much work has been done on the constitution of ultramarine, but the results obtained have not finally settled the question. From analyses and investigations made in 1891, Brögger & Bäckström (*W. J.* 1891. 454) conclude that the composition of the essential colouring compound in natural ultramarine is represented by the formula $Na_4[Al(S_2Na)]Al_2(SiO_4)_8$. They also conclude that artificial ultramarines may be expressed by the following formulæ:—

The main constituents of the different varieties of blue ultramarine are N, A, and $U(S_1)$; of green ultramarine $U(S_2)$ and N; and $U(S_1)$ is the main constituent of white ultramarine, according to B. & B. Formulæ more or less approaching those given above have been assigned to ultramarine by other observers; thus Silber in 1880 represented blue ultramarine as $Si_4Al_3Na_3S_3O_{12}$ (*B.* 18, 1854). On the other hand,

some chemists have regarded the essential constituent of ultramarine as a sodium thiosilicate; for instance, Rickmann (*B.* 11, 2013 [1878]) gives $S.Si(ONa)_2$ as the composition of 'ideal ultramarine blue'; and he regards artificial ultramarine as a mixture, the only essential part of which is sodium thiosilicate. Clarke (*Am.* 10, 126) suggested a formula for ultramarine which should indicate the relations of this body to various natural silicates; in this respect Clarke's formula is important (v. this vol. p. 451).

White ultramarine is obtained by completely cutting off air during the roasting of the materials; it is changed to blue by heating in O, SO_2 , or Cl (v. Ritter, *W. J.* 1160. 226; cf. Philipp, *B.* 9, 1109; 10, 1227; Böttger, *A.* 182, 311; R. Hoffmann, *A.* 194, 1).

Red ultramarine was observed by Scheffer, in 1873, to be formed in preparing the ordinary substance in a muffle furnace very strongly heated and freely exposed to the air; it contains less Na and more Al than the blue variety (*B.* 6, 1450; v. also Büchner, *D. P. J.* 231, 446; Zettner, *B.* 8, 259, 353).

Yellow ultramarine is formed by heating the red variety in the air a little above 360°, for a short time (R. Hoffmann, *A.* 194, 1). According to Büchner (*B.* 7, 990), both the yellow and red forms are produced by heating blue ultramarine to 300°–400° in O or SO_2 ; the colour changes to red and then to yellow. If Cl is passed over ultramarine before the formation of the blue variety is completed, at 410°, the colour goes green, and then reddish-yellow (Zettner, *B.* 8, 259, 353); by heating the product with alkali, all Cl is removed and a *violet ultramarine* is produced. This variety goes to the red form when heated in vapour of HNO_3 or HCl at 130°–150° (Zettner, *l.c.*).

Green ultramarine is formed when a little Sn is used in the roasting process; it is converted into the blue substance by roasting with S. This form seems to be intermediate between white and blue ultramarine. According to Philipp (*B.* 9, 1109), S is not taken up in the change from green to blue; by heating the green form in sealed tubes with water, at 100°, he obtained the blue, the water removing a very small quantity of sodium compounds.

Substituted ultramarines. Blue to green, and reddish-grey; substances have been formed by heating ultra marine with AgNO_3 aq, and by treating the product of this reaction with KI , LiI , BaI_2 , ZnI_2 , &c. These substances, known as *silver ultramarine*, *potassium ultramarine*, &c., probably contain Ag , K , Li , Ba , &c., in place of Na (v. Unger, *D. P. J.* 212, 224, 301; Philipp, *B.* 10, 1227; Heumann, *A.* 199, 253; 201, 262; Forcrand a. Ballin, *Bl.* [2] 30, 112). By heating silver ultramarine with various alcoholic iodides, Forcrand (*C. R.* 88, 30) obtained ultramarines containing alcoholic radicles, such as *ethyl ultramarine*, *amyl ultramarine*, &c. *Selenion* and *tellurium ultramarines* have also been produced, wherein S is substituted by Se or Te (v. Leykauf, *W. J.* 1876. 555; Guimet, *A. Ch.* [5] 13, 102; Ploque, *Bl.* [2] 23, 518; Morel, *Bl.* [2] 23, 522). Various substituted ultramarines have been examined by Wunder (*Chem. Zeit.* 1890. 1119). M. M. P. M.

ULMIC ACID. $\text{C}_6\text{H}_4\text{O}_3$; H . 4.6-4.5; O . 29-31.5. $\text{C}_6\text{H}_4\text{O}_3$ or $\text{C}_8\text{H}_6\text{O}_4$. H.C. 1983, 200. H.F. 266, 200. Formed by action of HCl on cane sugar. Is an anhydride or mixture of anhydrides $\text{C}_6\text{H}_4\text{O}_3$ (humic anhydride) (Berthelot a. André, *Bl.* [3] 7, 441, 451). Turns yellow in air and sunlight, giving off CO_2 . The same thing happens with the humic acid extracted from vegetable mould by KOH aq and ppd . by HCl . Dilute alkalis cause it to swell up, forming insoluble salts and a small quantity of a soluble basic salt. When conc. KOH aq is used a salt is formed, from which two-thirds of the alkali can be removed by washing, leaving $\text{KC}_6\text{H}_4\text{O}_3$ aq, and is reconverted into the acid $\text{C}_6\text{H}_4\text{O}_3$, by HCl aq. Ammonia converts humic anhydride (ulmic acid) into an amido-acid $\text{C}_6\text{H}_4\text{NO}_3\text{NH}_2$, whence HCl sets free $\text{C}_6\text{H}_4\text{NO}_3$. Salts.— $\text{KC}_6\text{H}_4\text{O}_3$ aq. Hard, black, insoluble mass, yielding a brown powder. The 'ulmin' of Malaguti. Formed by shaking the anhydride with KOH (1 pt.) and water (120 pts.). — $\text{NaC}_6\text{H}_4\text{O}_3$ aq.— $\text{Na}_2\text{C}_6\text{H}_4\text{O}_3$ 2aq.

References.—HUMIC, SACCHARUMIC, and SACULMIC ACIDS.

UMBELLIC ACID $\text{C}_8\text{H}_6\text{O}_3$, i.e. $[4:2:1] \text{C}_6\text{H}_3(\text{OH})_2\text{CH}:\text{CH}:\text{CO}_2\text{H}$. Mol. w. 182. **DI-OXY-CINNAMIC ACID.** Formed by warming its lactone, umbelliferone with KOH aq (Tiemann a. Reimer, *B.* 12, 994; Posen, *B.* 14, 2745). Yellowish powder. Turns brown at 240° , and decomposes below 260° . Sol. alcohol and warm water, insol. ether. Resinified by boiling its aqueous solution. Reduces warm ammoniacal AgNO_3 , forming a mirror. FeCl_3 gives a brown pp.

Methyl derivative $\text{C}_{10}\text{H}_{10}\text{O}_3$. $[180^\circ-185^\circ]$. Got by heating herniarin with alcoholic potash at 160° (Barth a. Herzig, *M.* 10, 165). Needles (from water).

(a) **Di-methyl derivative** $\text{C}_8\text{H}_4(\text{OMe})_2\text{CH}:\text{CH}:\text{CO}_2\text{H}$. $[138^\circ]$. Formed by the action of MeI and KOH in MeOH on the methyl derivative of umbelliferone in the cold (W. Will, *B.* 16, 2115; 19, 1777). Needles, v. sol. alcohol and ether. Converted into the (β)-isomeride by boiling alone or with HCl aq. Both isomerides are reduced by sodium-amalgam to the same $\text{C}_8\text{H}_4(\text{OMe})_2\text{CH}_2\text{CH}_2\text{CO}_2\text{H}$, and are oxidised by KMnO_4 to the same $\text{C}_8\text{H}_4(\text{OMe})_2\text{CO}_2\text{H}$. — CaA , 2aq: crystals. — BaA , 2aq: needles.

VOL. IV.

(β) **Di-methyl derivative.** $[184^\circ]$.

Formed as above, and also by saponification of its methyl ether $\text{C}_8\text{H}_4(\text{OMe})_2\text{CH}:\text{CH}:\text{CO}_2\text{Me}$ $[87^\circ]$, which is got by evaporating methyl-umbelliferone (1 mol.) with NaOH (2 mols.) nearly to dryness, and digesting the residue with MeI and MeOH (Tiemann a. Will, *B.* 15, 2079). Needles, sol. alcohol and ether. Sl. sol. cold water.

(a) **Di-ethyl derivative** $[4:2:1] \text{C}_6\text{H}_3(\text{OEt})_2\text{CH}:\text{CH}:\text{CO}_2\text{H}$. **Di-ethyl-umbelliferone** (5 g.) with EtI (10 g.) and a solution of KOH (4 g.) in alcohol (Will a. Beck, *B.* 19, 1780). Small plates, v. sol. alcohol, ether, and benzene.

(β) **Di-ethyl derivative.** $[200^\circ]$. Formed by boiling the (α)-isomeride for some time, and also by heating ethyl-umbelliferone (10 g.) with EtI (9 g.) and a solution of Na (2½ g.) in alcohol for six hours at 150° . Crystals, m. sol. alcohol, sl. sol. water.

UMBELLIFERONE $\text{C}_8\text{H}_6\text{O}_3$, i.e.

$\text{C}_6\text{H}_3(\text{OH})\text{CH}:\text{CH}:\text{CO}_2\text{H}$. Mol. w. 162. $[224^\circ]$. S.

1 at 100° . Formed by the dry distillation of various resins, chiefly those derived from umbelliferous plants, e.g. galbanum, sagapenum, and asafetida (Sommer a. Zwenger, *A.* 115, 15; Mössmer, *A.* 119, 260; Hlasiwetz a. Grabowski, *A.* 139, 100; Hirschsohn, *C. C.* 1877, 182). Formed by heating malic acid (1 mol.) with resorcin (1 mol.) and H_2SO_4 (Fechmann, *B.* 17, 932). Prepared by distilling the alcoholic extract of gum galbanum (Tiemann a. Reimer, *B.* 12, 993). Needles, sl. sol. cold water and ether, v. sol. alcohol. Dissolves in acids without change. Alkalis above 50° form umbellic acid. Its solution in dilute alkalis shows blue fluorescence. H_2SO_4 forms a solution with green fluorescence. Reduces AgNO_3 on boiling. Yields (4,2,1)-di-oxy-benzoic acid on oxidation (Tiemann a. Parrisius, *B.* 13, 2354). Fuming HNO_3 and H_2SO_4 form $\text{C}_8\text{H}_4(\text{NO}_2)_2\text{O}_3$ $[216^\circ]$ (Posen, *B.* 14, 2744).

Acetyl derivative $\text{C}_{10}\text{H}_8\text{O}_4$. $[140^\circ]$. Formed by acetylation, and also by boiling di-oxy-benzoic aldehyde with Ac_2O and NaOAc (Tiemann, *B.* 10, 2216; 12, 995). Needles, sl. sol. water.

Methyl derivative $\text{C}_{10}\text{H}_{10}\text{O}_3$, i.e.

$\text{C}_8\text{H}_5(\text{OMe})\text{CH}:\text{CH}:\text{CO}_2\text{H}$. $[114^\circ]$. Formed by heating umbelliferone with KOME and MeI (T. a. R.). Leaflets, nearly insol. water. Appears to be identical with herniarin $[118^\circ]$, which is extracted by alcohol from *Herniaria hirsuta* (Barth a. Herzig, *M.* 10, 161).

Ethyl derivative $\text{C}_{11}\text{H}_{12}\text{O}_3$. $[88^\circ]$. Plates, v. sol. alcohol (Will a. Beck, *B.* 19, 1779).

Oxim of the methyl derivative

$[4:2:1] \text{C}_8\text{H}_4(\text{OMe})\text{CH}:\text{CH}:\text{C}(\text{NOH})_2$. $[188^\circ]$. Formed from the methyl derivative of thio-umbelliferone and hydroxylamine (Aldringen, *B.* 24, 3465). Needles, v. sol. hot water and alcohol. FeCl_3 colours its solution brownish-red.

Phenyl-hydrazide of the methyl derivative $\text{C}_8\text{H}_4(\text{OMe})\text{CH}:\text{CH}:\text{C}(\text{NHPh})_2$. $[115^\circ]$. Yellow needles, giving a blue colour with H_2SO_4 .

Thio-umbelliferone. Methyl derivative
 $C_6H_3(OMe)<\begin{smallmatrix} CH:CH \\ O-CS \end{smallmatrix}> [114^\circ]$. Formed by heating the methyl derivative of umbelliferone with P_2S_5 (Aldringen, *B.* 24, 8465). Needles, sol. alcohol, v. sl. sol. water.

References.—Bromo- and METHYL-UMBELLIFERONE.

UMBELLOL C_6H_5O . (216°). V.D. 4.29. Occurs in the volatile oil of the Californian laurel (Stillmann, *B.* 18, 629). Oil, sol. H_2SO_4 , with red colour, becoming black. Attacked by Na.

UMBELLULIC ACID v. HENDECOIC ACID.

UNDECANE v. HENDECANE.

UNDECOIC ACID v. HENDECOIC ACID.

UNDECOLIC ACID v. HENDECINOIC ACID.

UNDECYLENE v. HENDECYLENE.

UNDECYLENIC ACID v. HENDECENOIC ACID.

UNDECYLIC ACID v. HENDECOIC ACID.

URACIL $CO<\begin{smallmatrix} NH:CH \\ NH:CO \end{smallmatrix}>CH$. *Di-oxy-pyrimidine*.

Derivatives of this compound are formed by the action of acetoacetic ether on urea, thio-urea, and guanidine (Behrend, *A.* 229, 1; 240, 6; List, *A.* 236, 1; Jäger, *A.* 262, 365; Warmington, *J. pr.* [2] 47, 201).

Amido-uracil $C_6H_4N_2O_2$. Formed, together with oxuracil $C_6H_4N_2O_2$, by reducing nitro-uracil (Behrend), and by boiling di-bromo-pyrimidine with baryta-water (Fischer, *A.* 239, 193). Yellow needles, sol. water. Converted by cyanic acid into oxyxanthine $C_6H_4N_2O_3$, which crystallises in needles, sl. sol. water, sol. alkalis, gives with Cl the murexide reaction, may be oxidised to alloxantin, and gives some alloxan with bromine-water.

Acetyl derivative $C_6H_4N_2O_3$, 3aq. Prisms.

Nitro-uracil v. NITRO-DI-OXY-PYRIMIDINE.

Bromo-nitro-oxy-uracil. Dihydrate

$C_6H_4N_2O_2Br$ i.e. $CO<\begin{smallmatrix} NH:CH(OH) \\ NH:CO \end{smallmatrix}>CBr(NO_2)$.

Formed by adding Br to nitro-uracil suspended in water (Behrend, *A.* 240, 11). Crystalline mass, sl. sol. cold water and alcohol. Boiling with water produces brominated nitro-methanes and a crystalline compound $C_6H_4N_2O_3$, formed by the action of urea upon nitro-uracil. Tin and HCl reduce it to amido-uracil.

Methyl-uracil v. DI-OXY-METHYL-PYRIMIDINE.

Nitro-methyl-uracil $C_6H_4N_2O_3$. Prepared by nitrating methyl-uracil with HNO_3 (S.G. 1.5) mixed with an equal volume of H_2SO_4 (S.G. 1.84) (Behrend, *A.* 240, 3). Prisms or tables (from water), sl. sol. hot alcohol.

Isomeride v. NITRO-DI-OXY-METHYL-PYRIMIDINE.

Nitro-di-methyl-uracil v. NITRO-DI-OXY-PYRIMIDINE.

Di-chloro-oxy-methyl-uracil. Dihydrate

$C_6H_4Cl_2N_2O_2$ i.e. $CO<\begin{smallmatrix} CMe(OH):NH \\ CO-NH \end{smallmatrix}>CO$.

Formed by the action of chlorine on methyl-uracil suspended in water (Behrend, *A.* 236, 59). Tables (from water); slowly decomposed by boiling water. M. sol. alcohol; not decomposed by boiling alcohol. M. sol. ether. A solution of $SnCl_2$ in $HClAq$ at 100° reduces it to chloro-methyl-uracil $C_6H_4ClN_2O_2$, which crystallises from water in needles. Fuming HNO_3 gives di-chloro-barbituric acid.

Di-bromo-oxy-methyl-uracil $J_6H_4N_2Br_2O_2$ i.e. $COBr<\begin{smallmatrix} CMe(OH):NH \\ CO-NH \end{smallmatrix}>CO$. From methyl-uracil (or bromo-methyl-uracil), and bromine-water (Behrend, *A.* 229, 18; 236, 57). Cubes (from hot water). Boiling alcohol converts it into bromo-methyl-uracil $C_6H_4N_2BrO_2$. Fuming HNO_3 forms di-bromo-barbituric acid.

Di-chloro-oxy-tri-methyl-uracil. Dihydrate
 $CO<\begin{smallmatrix} NMe:CO \\ NMe:CMe(OH) \end{smallmatrix}>OCl_2$. [144°]. Formed

by passing Cl into an aqueous solution of tri-methyl-uracil (Hagen, *A.* 244, 14). Crystals, sl. sol. hot water. Reduced by boiling with $SnCl_2$ to chloro-tri-methyl-uracil, which crystallises in prisms, m. sol. hot water.

Nitro-ethyl-uracil v. NITRO-DI-OXY-ETHYL-PYRIMIDINE.

Methyl-ethyl-uracil v. DI-OXY-METHYL-ETHYL-PYRIMIDINE.

Nitro-methyl-ethyl-uracil v. NITRO-DI-OXY-METHYL-ETHYL-PYRIMIDINE.

Amido-uracil carboxylic acid v. DI-OXY-AMIDO-PYRIMIDINE CARBOXYLIC ACID.

References.—THIO-METHYL-URACIL and URAMIDO-CROTONIC ACID.

URAMIDO-ACETIC ACID v. HYDANTOIC ACID.

p-URAMIDO-BENZENE SULPHONIC ACID $NH_2.CO.NH.C_6H_4.SO_3H$. Formed by evaporating a solution of p-amido-benzene sulphonic acid and potassium cyanate (Pellizzari, *A.* 248, 156), and also by heating dry p-amido-benzene sulphonic acid (1 mol.) with urea (1½ mols.) (Friedel, *C. R.* 112, 868). Pearly plates (from dilute alcohol), v. sol. water.— BaA' , 3aq; monoclinic prisms, sol. Aq.

o-URAMIDO-BENZOIC ACID $C_6H_4N_2O_2$ i.e. $NH_2.CO.NH.C_6H_4.CO_2H$. Formed from potassium cyanate and the hydrochloride of o-amido-benzoic acid (Griess, *J. pr.* [2] 5, 871; *B.* 11, 1730). HNO_3 yields only one di-nitro-derivative.

m-Uramido-benzoic acid $C_6H_4N_2O_3$. S. 1 at 100° . S. (96 p.c. alcohol) 72 at 16° . S. (ether) 127 at 16° . Occurs in urine after a dose of m-amido-benzoic acid (E. Salkowski, *H.* 7, 113).

Formation.—1. By adding potassium cyanate to a boiling saturated solution of the sulphate of m-amido-benzoic acid (Menschutkin, *A.* 153, 84; *Z.* [2] 4, 275).—2. By fusing m-amido-benzoic acid with urea (Griess, *Z.* [2] 5, 812; *B.* 2, 47).—3. By boiling m-cyanamido-benzoic acid with $HClAq$ (Traube, *B.* 15, 2122).

Properties.—Small prisms (containing aq), v. sl. sol. hot water. At 200° it yields $CO(NH.C_6H_4.CO_2H)_2$. On distilling m-uramido-benzoic acid (4 pts.) with P_2O_5 (1 pt.) m-amido-benzoic nitrile [54°] is formed (Griess, *B.* 8, 224). Boiling KOH splits it up into m-amido-benzoic acid, CO_2 , and NH_3 .

Salts.— NH_4A' aq. — KA' . — CaA' , 4aq. — PbA' , 2aq. — AgA' : curdy pp., becoming crystalline.

Ethyl ether EtA' . [176°]. Formed from m-amido-benzoic ether and $KCyO$ (Griess, *J. pr.* [2] 4, 293). Plates, sl. sol. hot water.

Amide $C_6H_4N_2O_3$. Formed from m-amido-benzamide and $KONO$ (Menschutkin). Scales (from water), decomposed by fusion, sl. sol. alcohol.

p-Uramido-benzoic acid $C_9H_7N_2O_4$. Formed in like manner (Griess, *J. pr.* [2] 5, 369). Plates, almost insol. cold water, v. sl. sol. hot water, m. sol. hot alcohol. Yields some *p*-amido-benzonitrile [86°] on distilling with P_2O_5 .— BaA' . Plates, v. e. sol. cold water.

Di-uramido-benzoic acid $C_{11}H_9N_4O_4$ i.e. $(NH_2.CO.NH).C_6H_4.CO_2H$. Formed by fusing di-amido-benzoic acid with urea (Griess, *B.* 2, 47). Small granules, v. sl. sol. hot water.— BaA'_2 (dried at 130°). Nodules, v. sol. hot water.

References.—AMIDO-, NITRO-, and OXY-URAMIDO-BENZOIC ACIDS.

URAMIDO-BENZOYL v. OXY-QUINAZOLINE.

p-URAMIDO-BENZOYL-UREA $C_{10}H_9N_5O_2$ i.e. $NH_2.CO.NH.C_6H_4.CH_2.NH.CO.NH_2$. [197°]. *p*-*o*-Di-uramido-toluene. Formed by heating together *p*-amido-benzyl-amine, hydrochloride (1 mol.), and KNO_3 (2 mols.) in aqueous solution (Amsel a. Hofmann, *B.* 19, 1289). Small needles. Sol. hot water.

URAMIDO-ISOBUTYRIC ACID v. ACETON-URAMIC ACID.

o-URAMIDO-CINNAMIC ACID $C_{10}H_9N_2O_4$ i.e. $NH_2.CO.NH.C_6H_4.CH:CH.CO_2H$. Formed from *o*-amido-cinnamic acid and aqueous KNO_3 (Rothschild, *B.* 23, 3341). Sol. NH_3Aq and hot $HClAq$.

(*β*)-**URAMIDO-CROTONIC ACID** $C_8H_7N_2O_4$ i.e. $CH_3.C(NH.CO.NH):CH.CO_2H$. The ether is converted by $NaOHAq$ into the salt NaA' , which crystallises in needles, v. sol. water; but on adding acids to this salt di-oxy-methyl-pyrimidine $C_4H_5N_2O_2$ is produced. Methyl-uracil is reconverted by $NaOHAq$ into sodium uramido-crotonate (Behrend, *A.* 229, 5).

Ethyl ether EtA' . [166°]. Formed from acetoacetic ether and urea. Needles, v. sol. ether, m. sol. alcohol. Decomposed by warm $HClAq$ into urea, acetone, CO_2 , and alcohol. Alcohol forms $CH_3.C(NH.CO_2Et):CH.CO_2Et$ [29°] (Meister, *A.* 244, 234).

Amide $CH_3.C(NH.CO.NH):CH.CO.NH_2$ [131°]. Crystals (containing $EtOH$) (Meister).

Amido-uramido-crotonic acid. Lactam.

$C_8H_7(NH_2)_2N_2O_2$ i.e. $CO \begin{smallmatrix} NH.CMe \\ NH.CO \end{smallmatrix} > C.NH_2 (?)$.

Amido-methyl-uracil. Methyl-uracil (v. Di-oxy-methyl-pyrimidine) is converted by Br in OS_2 into crystalline bromo-methyl-uracil $C_4H_5BrN_2O_2$, whence conc. NH_3Aq at 150° forms amido-methyl-uracil (Behrend, *A.* 231, 250). Satiny plates (from water), melting near 250°. Sol. alcohol. The hydrochloride is converted by potassium cyanate into oxy-methyl-xanthine $C_4H_5N_3O_2$, crystallising from water in prisms.— $B'HClAq$. Monoclinic crystals; $a:b:c = 1.629:1.2345$; $\beta = 52^\circ 57'$.— $B'_2H_2PtCl_2$, 2aq: needles, v. sol. water.

Acetyl derivative $C_8H_7(NHAc)_2N_2O_2$, 3aq. Formed from oxy-methyl-xanthine and Ac_2O at 170°. Thick trimetric prisms (from water). Decomposes near 210° without melting. Sol. alkalis and reppd. by acids.

URAMIDO-ETHANE SULPHONIC ACID

$NH_2.CO.NH.CH_2.CH_2.SO_3H$. *Taurocarbamie acid*. Occurs in small quantity in urine after a dose of taurine (E. Salkowski, *B.* 6, 744, 1191). Formed by evaporating a solution of taurine with $KCyO$. Formed also by the action of bromine-water on ethylene- ψ -thio-urea (Gabriel,

B. 22, 1142). Dimetric plates, v. sol. water, sl. sol. alcohol, insol. ether. Decomposed by baryta-water at 140° into CO_2 , taurine, and NH_3 .— BaA'_2 ; tables (from alcohol).— AgA' . Radiating tufts of crystals.

URAMIDO-HEXOIC ACID $C_8H_7N_2O_4$ i.e. $NH_2.CO.NH.CH(C_2H_5).CO_2H$. [200°]. Formed by boiling isobutyl-hydantoin with baryta-water (Pinner a. Spilker, *B.* 22, 696). Needles, v. sol. alcohol and hot water.— BaA'_2 : nodular groups of prisms.

Ethyl ether EtA' . [135°]. Formed by heating isobutyl-hydantoin with KOH and $EtBr$. Needles, v. sol. alcohol and hot water.

Nitrile. $NH_2.CO.NH.CH(C_2H_5).CN$. Formed by heating the cyanhydrin of isovaleric aldehyde with urea (Pinner a. Lifschütz, *B.* 20, 2351). Oil, sol. alcohol and ether. On warming with $HClAq$ it yields isobutyl-hydantoin

$C_4H_9.CH \begin{smallmatrix} CO.NH \\ NH.CO \end{smallmatrix}$ [210°].

Amide $NH_2.CO.NH.CH(C_2H_5).CO.NH_2$. [170°]. Formed from the nitrile (1 pt.) and conc. H_2SO_4 (8 pts.) in the cold. Crystals, v. sol. water and alcohol.

URAMIDO-HIPPURIC ACID $C_{10}H_9N_3O_4$. Formed by fusing *m*-amido-hippuric acid with urea (Griess, *J. pr.* [2] 1, 235). Nodules, v. e. sol. hot water. Decomposed by boiling conc. $HClAq$ into glycocoll and *m*-uramido-benzoic acid.— AgA' . Crystalline pp.

URAMIDO-NITRO-AMIDO-PHENOL $C_8H_5N_5O_4$ i.e. $C_6H_3(NO_2)(NH_2)(NH.CO.NH_2).OH$. Formed by reducing di-nitro-oxy-phenyl-urea with ammonium sulphide (Griess, *J. pr.* [2] 5, 1). Reddish-brown needles, sl. sol. hot water and alcohol.— $B'HCl$: white scales.— BaA' , 3½aq: steel-blue needles, v. sol. hot water. Boiling $HClAq$ converts it into amidocarboxamidodinitrophenol $C_6H_3N_3O_4$, which yields BaA' , 2aq and $B'HClAq$, and is reduced by tin and $HClAq$ to diamidocarboxamidophenol $C_6H_5N_2O_4$, which yields $B'HCl$, crystallising in plates.

URAMIDO-DI-NITRO-PHENOL v. Di-NITRO-OXY-PHENYL-UREA.

p-URAMIDO-PHENYL-ACETIC ACID $NH_2.CO.NH.C_6H_4.CH_2.CO_2H$. [174°]. Formed by boiling *p*-cyanamido-phenyl-acetic acid with $HClAq$ (Traube, *B.* 15, 2122). Small crystals (containing 1½aq), sol. water, alcohol, and ether.

α-Uramido-phenyl-acetic acid. *Ethyl ether* $NH_2.CO.NH.CHPh.CO_2Et$. [139°]. Formed by the action of aqueous $KCyO$ on the hydrochloride of *α*-amido-phenyl-acetic ether (Kossel, *B.* 24, 4150). V. sol. alcohol and hot water.

Nitrile $NH_2.CO.NH.CHPh.CN$. [170°]. Formed by heating the cyanhydrin of benzoic aldehyde with urea (Pinner a. Lifschütz, *B.* 20, 2351). Converted by acids into $C_8H_5N_3O_2$ [182°], crystallising in scales, v. sol. alcohol and hot water.

α-URAMIDO-PHENYL-CROTONIC ACID.

Nitrile $CHPh.CH.CH(NH.CO.NH_2).CN$. [160°]. Formed by heating urea with the cyanhydrin of cinnamic aldehyde (Pinner a. Lifschütz, *B.* 20, 2351). Needles, v. sol. hot alcohol. Boiling $HClAq$ converts it into di-oxy-styryl-pyrazole (*q. v.*).

Amide $CHPh.CH.CH(NH.CO.NH_2).CO.NH_2$. Formed from the nitrile and cold conc. H_2SO_4 (Pinner a. Spilker, *B.* 22, 692). Microcrystalline

powder, decomposing at 210°–220° with evolution of NH_3 . Sol. alcohol, sl. sol. hot water.

a-URAMIDO-PROPIONIC ACID $\text{C}_6\text{H}_5\text{N}_2\text{O}_4$, *i.e.* $\text{CH}_2\text{CH}(\text{NH}\cdot\text{CO}\cdot\text{NH}_2)\cdot\text{CO}_2\text{H}$. *Lacturamic acid*. [155°]. Formed by evaporating a solution of alanine sulphate mixed with KCyoO (Urech, *A.* 165, 99). Formed also by boiling lactyl-urea with baryta-water (Heintz, *A.* 169, 128). Prisms, sl. sol. cold water and alcohol, insol. ether.— $\text{BaA}'_2\text{aq}$ (dried at 100°).— $\text{PbA}'_2\text{aq}$.— AgA'_2 : needles, m. sol. water.

Nitrile $\text{CH}_2\text{CH}(\text{NH}\cdot\text{CO}\cdot\text{NH}_2)\cdot\text{CO}_2\text{H}$. [106°] (Franchimont & Klobbie, *R. T. C.* 7, 16).

Amide $\text{CH}_2\text{CH}(\text{NH}\cdot\text{CO}\cdot\text{NH}_2)\cdot\text{CO}_2\text{NH}_2$. [196°]. Small needles (from alcohol), sol. water.

URAMIDO-SUCCINIC ACID. *Amic acid* $\text{NH}_2\cdot\text{CO}\cdot\text{CH}_2\text{CH}(\text{NH}\cdot\text{CO}\cdot\text{NH}_2)\cdot\text{CO}_2\text{H}$. [188°] (G.). [157°] (P.). *Succinuramide*. *Amido-succinuric acid*. S. 5.4 at 23°. Formed by evaporating the mixed solutions of asparagine KCyoO (Guareschi, *G.* 7, 404; *B.* 10, 1747). Dextro-asparagine gives a *lævo*-compound, while *lævo*-asparagine gives a dextro-compound (Piutti, *B.* 19, 1693). Prisms, nearly insol. alcohol and ether. According to Piutti, the dextro- and *lævo*-compounds both melt at 157°.

Reactions.—1. Decomposed by fusion, with formation of malyl-ureide $\text{C}_6\text{H}_5\text{N}_2\text{O}_4$ [230°–235°], which is also formed by heating urea with asparagine at 125° (Grimaux, *A. Ch.* [5] 11, 400) and crystallises from water in pointed rhombohedra.—2. Boiling HClAq (S.G. 1.12) forms malyl-ureidic acid $\text{C}_6\text{H}_5\text{N}_2\text{O}_4$, which is also got by heating aspartic acid with urea at 130°. Malyl-ureidic acid crystallises in prisms [215°–220°], S. 25 at 100°, which yields $\text{BaA}'_2\text{aq}$ and is converted by heating with bromine-water into $\text{C}_6\text{H}_5\text{Br}_2\text{N}_2\text{O}_4$, S. 3 at 100°, $\text{C}_6\text{H}_5\text{Br}_2\text{N}_2\text{O}_4$, S. 25 at 100°, $\text{C}_6\text{H}_5\text{Br}_2\text{N}_2\text{O}_4$, which is v. sol. water, $\text{C}_6\text{H}_5\text{Br}_2\text{N}_2\text{O}_4$, S. c. 6 at 100°, and $\text{C}_6\text{H}_5\text{Br}_2\text{N}_2\text{O}_4$, S. 10 in the cold and c. 22 at 100°.

URAMIDO-THIO-FORMIC ACID *v.* **THIO-ALLOPHANIC ACID**.

DI-URAMIDO-TOLUENE *v.* **URAMIDO-BENZYL-UREA**.

DI-p-URAMIDO-DI-o-TOLYL-SULPHIDE [2:1:4] $\text{S}(\text{C}_6\text{H}_4\text{Me}\cdot\text{NH}\cdot\text{CO}\cdot\text{NH}_2)_2$. *Thio-p-tolyl-di-urea*. [151°] (when containing benzene of crystallisation). Formed by heating the hydrochloride of di-p-amido-di-tolyl-sulphide with KCNO (Truhlar, *B.* 20, 669). Crystallises from benzene in white silky needles (containing C_6H_6).

URAMIL $\text{C}_6\text{H}_5\text{N}_2\text{O}_4$, *i.e.* $\text{CO}\begin{smallmatrix} \text{NH}\cdot\text{CO} \\ \text{NH}\cdot\text{CO} \end{smallmatrix}\text{CH}\cdot\text{NH}_2$. *Dialuramide*. *Amido-barbituric acid*. *Amido-malonyl-urea*. *Murexan*. Mol. w. 143. Formed by boiling alloxantin with NH_4Cl (Liebig & Wöhler, *A.* 26, 310; Grimaux, *C. R.* 87, 752) and by boiling ammonium thionurate with HClAq . Formed also by reducing nitro- or nitroso-barbituric acid with HIAq (Baeyer, *A.* 127, 223). It is also a product of the action of acids on murexide (Beilstein, *A.* 107, 183).

Properties.—Silky needles, sl. sol. hot water, insol. alcohol and ether. Sol. conc. H_2SO_4 and re-ppd. on dilution. Its alkaline solution turns red in air, forming purpurates; thus it is converted in ammoniacal solution into murexide by boiling with air or HgO . Conc. HNO_3 forms alloxan.

Bromine at 85° forms orange $\text{C}_6\text{H}_5\text{BrN}_2\text{O}_4$ (Mulder, *B.* 14, 1060).

URAMILIC ACID $\text{C}_6\text{H}_5\text{N}_2\text{O}_4$ (?). S. 14 in the cold; 33 at 100°. Formed by heating uramil with H_2SO_4 and water, or by evaporating ammonium thionurate with some H_2SO_4 (Liebig & Wöhler, *A.* 26, 314; Gregory, *P. M.* 24, 187). Transparent, four-sided prisms, sl. sol. cold water. Converted by boiling conc. HNO_3 into nitro-barbituric acid.

URANATES *v.* **URANIUM, OXYACIDS AND SALTS** *OF, P.* 826.

URANIUM. U. At. w. 239 (not determined with very great accuracy). Mol. w. unknown. M.P. not determined accurately; between red heat and white heat. S.G. of fused U at 15° = 18.685 (Zimmermann, *B.* 15, 851). S.H. at 100° = 0.276 (Z., *l.c.*). S.V.S. 12.8.

Historical.—In 1789 Klaproth prepared some compounds of a new element from *pitchblende*; to the characteristic element of these compounds he gave the name uranium, from *ὕρανος* = the heavens, in allusion to the planet *Uranus* which had been discovered a few years before (Croll's *A.* 1789 [2] 400). The compounds of U were examined by Richter (Gehlen's *A.* 4, 402), Buchholz (Gehlen's *A.* 4, 17, 134), Lecanu (*J. Ph.* 9, 141; 11, 279), Brande (*S.* 44, 1), Berzelius (*P.* 1, 359), and Arfvedson (*P.* 1, 245). In 1840, Péligot showed that the substance supposed till then to be U was really an oxide of U (*A. Ch.* [3] 5, 5); P. isolated the metal, and determined the at. w. to be 120. Mendeléeff in 1872 (*A. Suppl.* 8, 133; *cf.* *C. N.* 41, 39 [1880]) proposed to double the at. w. of U, making it 240; this proposal was completely justified by the determination of S.H. of pure U by Zimmermann in 1882 (*B.* 15, 851), and by the determination of the V.D. of UCl_4 and UBr_4 (Z., *A.* 216, 2 [1883]).

Occurrence.—Never uncombined. A few minerals containing compounds of U are found sparsely distributed and not in large quantities; the chief of these is *pitchblende*, which consists of U_3O_8 along with SiO_2 and oxides of Sb, As, Ca, Cu, Fe, Mg, V, &c. Carbonate, sulphate, phosphate, niobate, tantalate, and various other compounds of U are also found in varying quantities in several rare minerals (*v.* Zimmermann, *A.* 232, 300; Hidden & Mackintosh, *Am. S.* [3] 88, 474; Hillebrand, *Am. S.* [3] 38, 329; 40, 384). Lockyer (*Pr.* 27, 49) stated that some of the lines in the emission-spectrum of U coincide with dark lines in the solar spectrum. Hutchins & Holden (*P. M.* [5] 24, 325) think there is no trustworthy evidence in favour of the existence of U in the solar atmosphere.

Preparation.—1. A mixture of UCl_4 , NaCl , and Na is strongly heated in a closed iron cylinder. Zimmermann (*A.* 116, 14) used a cylinder of soft iron with walls c. 8 centim. thick, bored from a larger cylinder (similar to that employed by Nilson & Petersson for preparing Be; *B.* 11, 883) fitted with a cap which could be screwed on tightly. He placed a layer of pure fused NaCl in the cylinder, then small pieces of Na (c. 3 to 4 pts. for 10 pts. UCl_4), then UCl_4 (which must be put into the cylinder as quickly as possible, as it is hygroscopic), and covered the whole with a layer of fused NaCl . Z. raised the cylinder to a white heat, kept it at

that temperature for some time, cooled, and washed the contents with dilute alkali solution, and then with water. According to Z., the metal as thus prepared is quite pure (*v. infra*).—2. Moissan (*C. R.* 116, 347) obtained U, containing from 5 to 13.5 p. C, by mixing the oxide prepared by strongly heating $\text{UO}_2(\text{NO}_3)_2$ with excess of charcoal, compressing the mixture in a carbon crucible, imbedding this in MgO , and heating for 10–12 minutes in an electric furnace, using a current of 60 volts and 450 ampères.

UCl_4 is obtained by heating the nitrate $\text{UO}_2(\text{NO}_3)_2$ in air, mixing the oxide thus obtained (chiefly U_3O_8) with C, and heating in a stream of Cl (*v.* URANIUM TETRACHLORIDE, p. 823). The nitrate is obtained from *pitchblende* by powdering the mineral, washing with water, drying, and washing to remove S and As, dissolving in HNO_3Aq , evaporating to dryness, dissolving in water, filtering from Fe_2O_3 , PbSO_4 , &c., evaporating a little, and allowing to crystallise. The crystals of $\text{UO}_2(\text{NO}_3)_2$ thus obtained are purified by draining in a funnel, washing with a little cold water, drying in the air, dissolving in ether in a wide-mouthed bottle, crystallising by spontaneous evaporation, and re-crystallising from hot water; the crystals of $\text{UO}_2(\text{NO}_3)_2$ are then dissolved in water so as to form a conc. solution, $\text{UO}_2\text{C}_2\text{O}_4$ is ppd. by adding $\text{H}_2\text{C}_2\text{O}_4\text{Aq}$ to this solution, the pp. is washed with boiling water, and then decomposed by heat, and the UO_2 thus produced is digested with conc. HClAq , washed, dissolved in HNO_3Aq , and the solution is crystallised (Péligot, *A. Ch.* [3] 5, 5, 12, 258; *cf.* Ebelmen, *A.* 43, 286; Wertheim, *J. pr.* 29, 209).

The oxide U_3O_8 used by Zimmermann (*v. supra*) for the preparation of UCl_4 from which pure U was obtained, was prepared by him as follows. A warm solution of commercial uranium hydroxide in HClAq was saturated with H_2S ; after standing for some time the liquid was filtered off, NH_3Aq and $(\text{NH}_4)_2\text{CO}_3\text{Aq}$ were added in excess, the liquid was warmed and $(\text{NH}_4)_2\text{SAq}$ was added; after standing the liquid was filtered, saturated with HClAq , and boiled till CO_2 was removed, then mixed with NH_3Aq and $(\text{NH}_4)_2\text{SAq}$ and heated on the water-bath till most of the $(\text{NH}_4)_2\text{S}$ was removed; the pp. of UO_2 was collected, washed, and heated over the blowpipe; the U_3O_8 thus formed was dissolved in HNO_3Aq and the solution was crystallised; the crystals of $\text{UO}_2(\text{NO}_3)_2$ were dissolved in ether, the solution was poured off from insoluble substances, evaporated to dryness, and the residue was strongly heated; the U_3O_8 which remained was again dissolved in HNO_3Aq , and the crystals that formed on evaporation were dissolved in ether, and the ethereal solution was evaporated to dryness and the residue decomposed by heating.

Properties.—A lustrous, hard, silver-white metal; S.G. 18.685 at 18° (Zimmermann, *B.* 15, 851); if UCl_4 is reduced by Na at a red heat, U is obtained as a greyish-black powder. S.H. at $100^\circ = .0276$ (Z., *l.c.*). U is somewhat malleable, but cannot be hammered into thin plates. The emission-spectrum, obtained by the aid of electric sparks, shows only a few lines, the most marked being one in the yellow (Thalén, *A. Ch.*

[4] 18, 239). For the fluorescence, phosphorescence, and absorption-spectra of U compounds *v.* Becquerel (*A. Ch.* [4] 27, 539), also Morton A. Bolton (*Am. Ch.* 3, 361, 401). U melts towards a white heat; according to Moissan (*C. R.* 116, 1429), the metal is volatilised by heating in an electric furnace using a current of 350 ampères and 75 volts. After long standing in the air the surface of U becomes covered with a steel-blue to black film of oxide; U that has been fused burns brilliantly when heated on Pt foil in the air; pulverulent U burns at $150^\circ\text{--}170^\circ$ in the air. U combines directly with Cl or Br, also with S; the metal dissolves in dilute $\text{H}_2\text{SO}_4\text{Aq}$ or HClAq ; it is not acted on by acetic acid, nor by KOH Aq , NaOH Aq , or NH_3Aq .

The at. w. of U has been determined (1) by determining U and Cl in UCl_4 (Péligot, *A. Ch.* [3] 5, 12 [1842]; Rammelsberg, *P.* 55, 318; 56, 125 [1842]); (2) by analyses of $\text{UO}_2\text{C}_2\text{O}_4\text{H}_2\text{O}$ (Ebelmen, *A. Ch.* [3] 5, 191 [1842]; Péligot, *A. Ch.* [3] 20, 341 [1846]); (3) by analyses of $\text{UO}_2(\text{C}_2\text{H}_3\text{O}_2)_2\cdot 2\text{H}_2\text{O}$ (Péligot, *l.c.*; Wertheim, *J. pr.* 29, 207); (4) by analyses of the double salt $\text{UO}_2\text{Na}(\text{C}_2\text{H}_3\text{O}_2)_3$ (Wertheim, *l.c.*); (5) by transforming UO_2 into U_3O_8 , and $\text{UO}_2\text{Na}(\text{C}_2\text{H}_3\text{O}_2)_3$ into Na_2UO_4 (Zimmermann, *A.* 232, 117, 273 [1886]); (6) by determining S.H. of U (Zimmermann, *B.* 15, 851 [1882]); (7) by determining V.D.s of UBr_4 and UCl_4 (Z., *A.* 216, 2 [1883]).

The at. w. of U was formerly taken as c. 120; in 1872 Mendeléeff adduced reasons for doubling this value, based on a comparative study of the properties of compounds of U to which he was led by considering the periodic arrangement of the elements (*A. Suppl.* 8, 178; *C. N.* 41, 39). When the at. w. of U was taken as 120, the formulæ given to the chief oxides, chlorides, and salts of this element were UO , UCl_2 , USO_2 , &c.; U_2O_3 ; U_2O_5 , UOCl , $\text{UO}(\text{NO}_3)$, &c.; and U was classed with the iron metals. Mendeléeff pointed out that U was very much heavier than the iron metals, that the oxide U_3O_8 did not form salts similar to those derived from Fe_2O_3 , that the salts of U, *i.e.* USO_4 , $\text{U}(\text{NO}_3)_2$, &c., were not isomorphous with the salts of MgO , FeO , NiO , &c. Mendeléeff also drew attention to the existence of a chloride which would have to be represented as U_2Cl_4 if U = 120, and that this chloride was obtained by heating UCl_4 in H. Mendeléeff proposed to double the value then accepted for the at. w. of U, and, following on this, to write the formulæ of the chlorides, oxides, and salts as UCl_3 , UO_2 , $\text{U}(\text{SO}_4)_2$, &c.; U_3O_8 ; UO_3 , UO_2Cl_2 , $\text{UO}_2(\text{NO}_3)_2$, &c.; and UCl_5 . It was pointed out that many of these formulæ are analogous to those of the corresponding compounds of Cr, Mo, and W; and it was shown that the properties of compounds of U more nearly resemble those of compounds of Cr, Mo, and W than of any other elements. Especial stress was laid by Mendeléeff on the acidic character of the highest oxide of U. Finally, Mendeléeff showed that an element with the properties of U, and an at. w. equal to c. 240, finds its proper place in Group VI., series 12, of the periodic arrangement of the elements. Mendeléeff suggested that the S.H. of pure U should be determined; that the V.D. of the volatile chloride should be found; that the action of H

on the chloride then taken to be UCl_4 should be studied; that salts of the lower oxide (UO if $\text{U}=120$, UO_2 if $\text{U}=240$) should be examined, especially as regards their isomorphism with salts of ThO_2 , SnO_2 , ZrO_2 , and TeO_2 ; that the crystalline forms of corresponding compounds of MoO_3 , WO_3 , and UO_2 ($\text{U}=240$) should be studied, and that an especially thorough crystallographic examination should be made of the compounds $\text{R}_2\text{UO}_2\text{F}_4$; and that the physical properties of compounds of Cr, Mo, W, and U should be compared. Since the publication of Mendeléeff's memoir, the S.H. of U, and the V.D.s of UBr_3 and UCl_4 have been determined, the action of H on UCl_4 has been examined, and something has been done in the study of the crystalline forms of compounds of U, including those of the form $\text{R}_2\text{UO}_2\text{F}_4$; the results of all these investigations fully confirm the justness of Mendeléeff's view that the at. w. of U is c. 240, and that this element must be classed with Cr, Mo, and W. The exact value to be given to the at. w. of U has not been yet determined; Zimmermann's measurements gave 238.75 from the ratio $\text{UO}_2:\text{U}_2\text{O}_5$, and 238.67 from the ratio $\text{UO}_2\text{Na}(\text{C}_2\text{H}_3\text{O}_2)_2:\text{Na}_2\text{UO}_4$ ($\text{O}=15.96$). The mol. w. of U is not known.

U is the last member of the even-series family of Group VI.; this family also contains, besides O, the elements Cr, Mo, —, and W. The chromium elements are both metallic and non-metallic in their chemical relations; they form oxides MO_3 that are acidic, and some of the lower oxides are basic. The oxide UO_2 forms some corresponding salts; a series of salts of the form UO_2X is also known, where $\text{X}=\text{SO}_4$, &c. Several series of uranates M_2UO_7 , $\text{M}_2\text{U}_2\text{O}_9$, &c., are known. The haloid compounds are UX_3 , UX_4 , and UX_5 . (For a comparison of the metals of the Cr family v. CHROMIUM GROUP OF ELEMENTS, vol. ii. p. 168; cf. CLASSIFICATION, vol. ii. p. 207.)

The atom of U is tetravalent in the gaseous molecules UBr_4 and UCl_4 .

Reactions and Combinations.—1. Heated in air U is burnt to a voluminous deposit of U_2O_5 (perhaps containing also UO_3), which stops the further oxidation of the metal. Pulverulent U burns when heated in air to $150^\circ\text{--}170^\circ$.—2. U burns brilliantly when heated in chlorine, forming UCl_4 ; heated in bromine to c. 240° part of the metal is changed to UBr_3 .—3. Heated in sulphur vapour US_2 is produced.—4. It is generally said that U does not react with water; but, according to Moissan (*C. R.* 116, 347), the metal obtained by him by reducing the oxide by charcoal in an electric furnace decomposed water at the ordinary temperature; this specimen of U contained from 5 to 18.5 p.c. C.—5. U dissolves in dilute sulphuric acid, rapidly on warming, forming USO_4 , and giving off H; pulverulent U dissolves in hot conc. H_2SO_4 , giving off SO_2 ; the compact metal is scarcely acted on by conc. H_2SO_4 .—6. U dissolves in hydrochloric acid, dilute or conc., rapidly on warming, forming a hyacinth-red solution of UCl_3 , which goes green on shaking in air, and then contains UCl_4 .—7. Conc. nitric acid, even when hot, scarcely acts on U that has been fused; the pulverulent metal is quickly oxidised by hot conc. HNO_3 to U_2O_5 .—8. Several metallic salts in solution

are reduced by U, with ppn. of the metals, e.g. HgNO_3 , AgNO_3 , CuSO_4 , SnCl_4 , PbCl_2 , AuCl_3 .

Detection and Estimation.—Uranyl salts (UO_2SO_4 , &c.) are formed by heating uranates with acids, also by the reactions of acids with UO_3 , and also by oxidising uranous salts (salts of UO). $\text{K}_2\text{FeCy}_4\text{Aq}$ gives a brownish-red pp. with uranyl salts, soluble in HClAq or in $(\text{NH}_4)_2\text{CO}_3\text{Aq}$; this reaction is said to be extremely delicate; $\text{H}_2\text{O}_2\text{Aq}$ and alcohol give a brown pp. (Fairley, *C. N.* 62, 227); carbonates give yellow pps., soluble in excess, forming yellow liquids; NaOHAq or KOHAc forms yellow pps., NH_4ClAq does not interfere with the ppn., but in presence of sugar or tartaric acid pps. are not produced. Uranous salts are produced by reducing uranyl salts in solution by Zn and HClAq . After reduction the solutions give green pps. with KOHAc or NaOHAq , the pps. becoming brown and then yellow in the air; with $(\text{NH}_4)_2\text{SAq}$ green pps. are formed, quickly becoming dark green, and black on boiling; $\text{K}_2\text{FeCy}_4\text{Aq}$ produces yellow-green pps. becoming red in the air (v. Zimmermann, *A.* 213, 285).

U is generally estimated as UO_2 or U_2O_5 (v. Zimmermann, *A.* 232, 209). Solutions may be reduced by Zn and $\text{H}_2\text{SO}_4\text{Aq}$, and then titrated with KMnO_4Aq , the quantity of O used corresponding with the change of UO_2 to UO_3 (*Z.*, *l.c.*; v. also Bělohoubek, *J. pr.* 99, 231).

Uranium, arsenates of. A compound, probably $\text{UO}_2\text{As}_2\text{O}_5 \cdot 4\text{aq}$, is described by Rammelsberg (*P.* 59, 26). Werther (*J. pr.* 43, 321) describes $\text{UO}_2\text{H}_2\text{AsO}_4 \cdot 3\text{aq}$, and various double salts of this compound with arsenates of Ca, Cu, and Na.

Uranium, bromides of. UBr_3 is formed by heating U_2O_5 mixed with C in Br vapour; and UBr_4 by heating UBr_3 in H. Zimmermann (*A.* 216, 5) failed to obtain a compound with more Br by heating UBr_3 with Br to 230° in a sealed tube.

URANIUM TETRABROMIDE UBr_4 . (*Uranous bromide*.) Mol. w. 558. Prepared by strongly heating a mixture of U_2O_5 and sugar, mixing with sugar charcoal that has been heated to redness, placing the mixture in a tube, and heating it first in a stream of thoroughly dried CO_2 , and then in Br vapour, and allowing to cool in CO_2 ; the Br used must be perfectly freed from Cl, HBr, and H_2O by distillation from KBr, MnO_2 , and P_2O_5 (Zimmermann, *A.* 216, 2; Alibegoff, *A.* 232, 132; cf. Hermann, *J.* 1861, 260). UBr_4 forms black, fusible leaflets; volatile at red heat, giving a vapour with V.D. 281 (*Z.*, *l.c.*); very hygroscopic; dissolves in water, with a hissing sound, forming a green liquid.

By evaporating a solution of $\text{UO}_2 \cdot x\text{H}_2\text{O}$ in HBrAq , Rammelsberg (*P.* 59, 12) obtained green crystals of hydrated UBr_3 , probably $\text{UBr}_3 \cdot 8\text{H}_2\text{O}$.

Uranoxym bromides. (*Bromoxy-uranates*.) $\text{UO}_2\text{Br} \cdot 2\text{MBr}$ or $\text{M}_2\text{UO}_2\text{Br}_4$. By the reaction of HBrAq with K_2UO_4 and $(\text{NH}_4)_2\text{UO}_4$, respectively, Sendtner (*A.* 195, 325) obtained yellowish, hygroscopic tablets of the composition $\text{M}_2\text{UO}_2\text{Br} \cdot 2\text{H}_2\text{O}$, where $\text{M}=\text{NH}_4$ and K.

URANIUM TRIBROMIDE UBr_3 . Mol. w. not determined. Obtained by Alibegoff (*A.* 233, 119; cf. Zimmermann, *A.* 216, 5) by passing dry H over molten UBr_4 . Dark-brown needles; easily

volatilised; not changed by continued heating in H; very hygroscopic; warmed in H_2S , in complete absence of air, forms U_2S_3 .

Uranium, chlorides of. By heating U in Cl both UCl_3 and UCl_4 are produced; and by heating UCl_3 in H, UCl_4 is formed.

URANIUM PENTACHLORIDE UCl_5 . Mol. w. not determined; formula probably molecular, from analogy of $MoCl_5$ and WCl_5 .

Preparation.—1. By heating U in excess of Cl.—2. A slow stream of dry Cl is passed over a mixture of charcoal and any oxide of U, or UO_2Cl_2 , heated to dull redness in a glass tube; dark-green octahedral crystals of UCl_4 are formed near the heated part of the tube, and in front of these needle-shaped crystals of UCl_5 are deposited, mixed with a loose brown powder, which is also UCl_5 . If the stream of Cl is rapid, most of the UCl_5 is produced as a light-brown, mobile powder (Roscoe, *C. J.* [2] 12, 933).

Properties and Reactions.— UCl_5 crystallises in long, dark, needle-shaped forms; the crystals are lustrous, and reflect greenish light, in transmitted light they are dark ruby red. Both the crystals and the brown powder are very hygroscopic. Dissolves in water, with a hissing sound, forming a yellow-green liquid and giving off HCl. Decomposed to UCl_4 and Cl when heated, either alone or in CO_2 or Cl; decomposition begins at 120° in CO_2 , and is complete at 235° . Heating in NH_3 probably produces a nitride (Roscoe, *l.c.*; no analyses given).

Combination.—A compound $UCl_5.PCl_5$ is described by Cronander (*J.* 1873. 222) as an amorphous, yellow solid; formed by heating UO_2 with excess of PCl_5 in a sealed tube for a long time.

URANIUM TETRACHLORIDE UCl_4 . (*Uranous chloride*.) Mol. w. 380.48.

Preparation.—1. U is heated in Cl.—2. A mixture of charcoal and an oxide of U, or UO_2Cl_2 , is heated in a slow stream of dry Cl (Péligot, *A.* 43, 258; *cf.* Roscoe, *C. J.* [2] 12, 933). The crystals that form nearest to the heated part of the tube are again heated in a stream of dry CO_2 , whereby traces of UCl_5 are volatilised and removed (Zimmermann, *A.* 216, 8).—3. A solution of ammonium uranate in $HClAq$ is reduced by Zn, and the solution is evaporated and crystallised. Arendt a. Knop (*C. C.* 1857. 164) reduced, by boiling the solution for 15 min. with Cu and a little $PtCl_4Aq$; they then filtered, saturated with H_2S , filtered, boiled off H_2S , and crystallised.

Properties and Reactions.—Dark-green, lustrous, regular octahedral crystals; volatilises at red heat, in complete absence of moisture, giving a red vapour (Péligot, *l.c.*) with V.D. 192 (Zimmermann, *l.c.*). Very deliquescent; fumes much in air, giving off HCl; dissolves in water, with a hissing sound, forming a green solution that is unchanged in air; gives green, amorphous UCl_3 by evaporation *in vacuo*, but is decomposed by evaporation in the air. When UCl_4Aq is dropped into boiling water all the U is ppd. as $UO_2.xH_2O$. Solution of UCl_4 reduces salts of Au and Ag to the metals, and $FeCl_3$ to $FeCl_2$, &c. By heating in dry H one-fourth of the Cl is removed, and UCl_3 remains (Péligot, *A.* 43, 266). According to Péligot (*l.c.*), UCl_4 com-

bines with several metallic chlorides to form double salts.

Uranoxychlorides. (*Chloroxyuranates*.) $UO_2Cl_2.2MCl.2aq$, or $M_2UO_2Cl_4.2aq$. Salts of this composition, $M = NH_4$ and K, are produced by the reaction of large excess of $HClAq$ with uranates of NH_4 and K (Péligot, *A.* 43, 279). The K compound is also formed by acting on UO_2Cl_4 with excess of $KClAq$, and separating the KCl that crystallises with the $K_2UO_2Cl_4$ mechanically (Berzelius, *P.* 1, 366). The K compound forms thick plates (for crystalline measurements *v. de la Provostaye, A. Ch.* [3] 6, 165); easily loses water; gives off HCl at a little above 100° ; melts at red heat, giving off Cl, and leaving UO_2 and KCl. The ammonium compound forms very deliquescent rhombohedra.

URANIUM TRICHLORIDE UCl_3 . Mol. w. not determined. Obtained by Péligot (*l.c.*) by heating UCl_4 in dry H as long as HCl was given off. Also formed in solution by long-continued reduction of uranyl salts by Zn and $HClAq$ (Zimmermann, *A.* 213, 300). A brownish-red solid; dissolves very readily in water, forming a red solution, which gives off H and becomes green (*v. P., l.c.*; *Z., l.c.*; also *A.* 216, 12).

Uranium, ferrocyanides of. Various compounds are described by Wyruboff (*A. Ch.* [5] 8, 444) and Atterberg (*Bt.* [2] 24, 355) as obtained by ppg. K_4FeCy_6Aq by solutions of salts of U. The following formulæ are given:

- (1) $U_2FeCy_6.10aq$; (2) $U_2K_2FeCy_6.6aq$;
- (3) $(UO_2)_2K_2(FeCy_6)_2.6aq$;
- (4) $(UO_2)_2K_4(FeCy_6)_4.12aq$.

Uranium, fluorides of. Only one compound, UF_4 , has been isolated with certainty.

URANIUM TETRAFLUORIDE UF_4 . (*Uranous fluoride*.) Mol. w. not determined; formula probably molecular, from analogy of UBr_4 and UCl_4 . Prepared by adding $HFAq$ to U_2O_5 , boiling, pouring off the yellow solution (which contains UO_2F_2), washing the green powder that remains, first on a filter and then by decantation, until free from $HFAq$, and drying at 100° (Smithells, *C. J.* 43, 125; *cf.* Bolton, *Z.* [2] 2, 353). The process of washing is very tedious, and occupies many days. UF_4 is a green powder; insol. in water and dilute acids; slowly dissolved by conc. acids; boiling $NaOHAq$ produces UO_2 . Heated in a Pt crucible with the lid on, a small quantity of a white, bulky sublimate is obtained; this sublimate is UO_2F_2 (Smithells, *l.c.*); the residue in the crucible is chiefly UO_2 . Heated on Pt foil, UF_4 leaves U_2O_5 (*S., l.c.*).

Double salts.—Bolton (*l.c.*) obtained the compounds $UF_4.KF$ and $UF_4.NaF$ —as green powders, insoluble in water and dilute acids, giving UO_2 , KF (or NaF), and HF when heated to redness, in closed vessels—by the action of formic or oxalic acid on $UO_2F_2.8KF$ or $UO_2F_2.NaF$ (*v. infra*) in sunlight. These compounds may be called *uranofluorides*, and written KUF_5 and $NaUF_5$.

Uranium hexafluoride UF_6 , was said by Ditte (*C. R.* 91, 115) to be formed by heating U_2O_5 with $HFAq$, evaporating the yellow liquid, and heating the crystals of $UF_4.8HF$ thus obtained; but Smithells (*C. J.* 43, 125) has shown that the substance obtained by evaporating the

solution formed by heating U_3O_8 with $HFAq$ is UO_2F_2 (v. URANIUM OXYFLUORIDE, p. 828).

Uranoxylfluorides. (*Fluorxy-uranates.*) These compounds may be regarded either as double salts of UO_2F_2 with alkali fluorides, or as salts derived from hypothetical acids $H_xUO_2F_x$. The compounds are formed by adding alkali fluorides to solutions of uranous nitrate, and crystallising under different conditions (v. Bolton, *Z.* [2] 2, 353; Baker, *C. J.* 35, 763). The compounds that have been isolated belong to several series: (1) $MF \cdot UO_2F_2 \cdot xaq = MUO_2F_2 \cdot xaq$, where $M = Na$ and $x = 2$ and 4 (Bolton); (2) $3MF \cdot UO_2F_2 = M_3UO_2F_6$, where $M = NH_4$ and K (Bolton; Baker); (3) $3KF \cdot 2UO_2F_2 \cdot 2aq = K_3U_2O_4F_6 \cdot 2aq$ (Baker); (4) $5KF \cdot 2UO_2F_2 = K_5U_2O_4F_6$ (Baker); (5) $3BaF_2 \cdot 5UO_2F_2 \cdot 2aq$ (Bolton). Two other series were described by Ditte (*C. R.* 91, 166), $4MF \cdot UO_2F_2$ and $4MF \cdot UOF_4 \cdot xaq$; but the experiments of Smithells (*C. J.* 43, 131) have shown that these compounds do not exist.

Uranium, haloid compounds of. U combines directly with Br and Cl, but not with I; no iodide, indeed, has been isolated. The haloid compounds of U belong to the form UX_x , where $X = Br$ or Cl ; UX_x , where $X = Br, Cl$ or F ; and UX_x , where $X = Cl$. The compounds UBr_4 and UCl_4 have been gasified, and the formulæ are molecular. From the analogy of WCl_4 and $MoCl_4$, the formula UCl_4 is probably molecular; this compound decomposes to UCl_3 and Cl when heated, either alone or in CO_2 or Cl . From the analogy of $CrCl_3$, it may be supposed that UCl_3 and UBr_3 are molecular formulæ. No haloid compounds of U have been isolated corresponding with the chlorides of Cr, Mo, and W, M_2Cl_6 . No haloid compounds of U are known containing each more than one halogen. Various oxyhaloid compounds, chiefly UO_2X_2 , and compounds of these with alkali haloids, are known.

Uranium, hydroxides of, v. URANIUM, OXIDES AND HYDRATED OXIDES OF (infra); also URANIUM OXYACIDS, AND SALTS OF (p. 826).

Uranium, iodides of. No compound of U and I has been isolated. Hermann (*J.* 1861, 260) and Sendter (*Verbind. des Uraniums*, Erlangen, 1877) failed to obtain an iodide by heating a mixture of UO_2 and I in vapour or in HI .

Uranium, nitride of, U_3N_4 . A greyish-black powder; obtained by heating UCl_4 in NH_3 , then mixing with NH_4Cl and heating for a long time in a stream of NH_3 (Uhrlaub, *Verbind. einiger Metalle mit Stickstoff*, Göttingen, 1859). Roscoe (*C. J.* [2] 12, 933) states that a nitride is formed by heating UCl_4 in NH_3 , but no analyses are given.

Uranium, oxides and hydrated oxides of. When U is burnt in air the product is U_3O_8 ; by heating this oxide with reducers, or for a long time in a stream of N or CO_2 , UO_2 is formed; UO_2 is produced by fusing U_3O_8 with $KClO_3$, also by heating $UO_2(NO_3)_2$; by adding H_2O_2Aq to $UO_2(C_2H_3O_2)_2Aq$ or $UO_2(NO_3)_2Aq$ a hydrate of UO_2 is obtained. Besides these four oxides, others, intermediate between UO_2 and U_3O_8 , perhaps exist. No definite hydrate of UO_2 has been isolated; the pp. formed by adding NH_4Aq to UCl_4Aq , or to solution of a uranous salt ($U(SO_4)_3$, &c.), is either a hydrate, or a

mixture of hydrates, of UO_2 . A hexahydrate of UO_2 probably exists. Uranic acid is the monohydrate of UO_2 . UO_2 dissolves in some acids to form corresponding salts; U_3O_8 is said to react with conc. H_2SO_4 or $HClAq$ to form both uranous salts UX_3 , and uranyl salts UO_2X , where $X =$ a divalent acidic radicle. UO_2 interacts with several acids to form uranyl salts UO_2X_2 ; UO_2 also reacts as an acidoid oxide with strong bases, forming uranates, di-uranates, &c., M_2UO_4 , $M_2U_2O_7$, &c.

According to Guyard (*Bl.* [2] 1, 89), two oxides having the compositions UO and U_2O_3 exist; but the more accurate investigations of Zimmermann (*A.* 213, 301) showed that the substances examined by Guyard were not definite compounds. Pélégot described a black oxide U_3O_5 ; Zimmermann (*A.* 232, 273) has shown that the substance is a mixture, in variable proportions, of UO_2 and U_3O_8 .

URANIUM DIOXIDE UO_2 (Uranous oxide.) Mol. w. not known. This oxide was supposed to be the element U until 1840, when Pélégot proved the presence of O in the substance (*A. Ch.* [3] 5, 5).

Formation.—1. By heating U_3O_8 with such reducing agents as H (Arfvedson, *P.* 1, 245), NH_4Cl and S (Hermann, *J.* 1861, 258), a little C (Buchholz, *Gehlen's Ann.* 4, 17, 134), oxalic acid (Wertheim, *J. pr.* 29, 211), &c.—2. By heating U_3O_8 for a long time in a stream of N or CO_2 (Zimmermann, *A.* 232, 283).—3. By strongly heating $UO_2 \cdot C_2O_4$ in absence of air (Berzelius, *P.* 1, 359), or in a stream of H (Pélégot, *A. Ch.* [3] 5, 5; Ebelmen, *A. Ch.* [3] 5, 189).

Preparation.—A mixture of UO_2Cl_2 and excess of $NaCl$ and NH_4Cl is strongly heated in absence of air; and the product is washed thoroughly with water, and dried (Wöhler, *A.* 41, 345; cf. Hillebrand, *Zeit. f. anorg. Chemie*, 3, 243). If air is not excluded during heating, some UO_3 is obtained (H., *l.c.*). This process gives UO_2 as a black crystalline powder. In place of using UO_2Cl_2 , a solution of ammonium uranate in $HClAq$ may be mixed with excess of $NaCl$ and NH_4Cl , and evaporated to dryness, and the residue heated. By fusing any oxide of U with borax for 24 hours, and washing with water and then with dilute acetic acid, or dilute $HClAq$, Hillebrand (*l.c.* p. 249) obtained jet-black octahedra of UO_2 isomorphous with ThO_2 .

Properties.—Prepared by heating $UO_2 \cdot C_2O_4$, UO_2 is a dark-brown, pyrophoric powder; if the temperature has been kept high the oxide is lustrous, reddish-black, and not pyrophoric; prepared by heating UO_2Cl_2 with $NaCl$ and NH_4Cl , UO_2 forms black, non-pyrophoric, octahedral crystals. Pélégot gave S.G. 10.15; according to Hillebrand (*l.c.*), the S.G. is nearly 11. UO_2 is insoluble in water, $HClAq$, and dilute H_2SO_4Aq ; it dissolves in HNO_3Aq , and in conc. H_2SO_4 in presence of a little water. UO_2 is oxidised to U_3O_8 by heating in air.

Reactions.—1. Heated in air or oxygen U_3O_8 is produced; UO_2 burns brilliantly in the O-H flame (Clarke, *G. A.* 62, 853).—2. Heating in chlorine produces UO_2Cl_2 ; when mixed with carbon and heated in chlorine, UCl_4 and UCl_3 are formed. UBr_4 is produced by heating UO_2 mixed with carbon in bromine vapour.—3. U_3O_8 is formed by heating UO_2 in water vapour

(Regnault, *A. Ch.* [2] 62, 358).—4. Heating in vapour of carbon disulphide produces $U_2O_3S_2$ (Hermann, *J.* 1851. 258; H. Rose, *G. A.* 73, 139). UO_2 is said to be unchanged by heating in hydrogen sulphide (Arfvedson, *P.* 1, 245).—5. A solution of UO_2 in conc. sulphuric acid gives green crystals of $U(SO_4)_2$ on evaporation.

HYDRATES OF URANIUM DIOXIDE. No definite hydrate of UO_2 has been isolated; NH_4Aq produces a reddish-brown pp. when added to UCl_4Aq or solution of a uranous salt, this pp. becomes black on boiling; when washed with air-free water and dried *in vacuo* it forms black, coherent lumps. A black pp. is also produced by dropping UCl_4Aq into boiling water. These black pps. contain UO_2 ; they are probably hydrates of this oxide. The name *uranous hydroxide* is often given to the pp. obtained by either of the processes described; the pp. dissolves in dilute H_2SO_4Aq , HNO_3Aq , and $HClAq$.

URANOSO-URANIC OXIDE U_3O_8 . (*Olive-green oxide of uranium.* *Uranyl uranate* $UO_2 \cdot 2UO_3$.) Mol. w. not known.

Occurrence.—In combination with SiO_2 , and oxides of Sb, As, Ca, Cu, Fe, Mg, &c., in *pitchblende*.

Preparation.—U, or a decomposable U compound, e.g. $UO_2(NO_3)_2$, is heated in the air and then in a stream of O, and is allowed to cool in O (*v.* Zimmermann, *A.* 232, 283). For a method of preparing U_3O_8 from *pitchblende v.* URANIUM, *Preparation of* (p. 821).

Properties.—A dark olive-green powder, sometimes almost black, but always showing a green streak when rubbed on unglazed porcelain (*Z.*, l.c.). S.G. 7.2 (Karsten, *S.* 65, 394); 7.31 (Ebelmen, *J. pr.* 27, 385). S.H. .07979 (Donath, *B.* 12, 742). Insoluble in water; slightly soluble in dilute $HClAq$ or H_2SO_4Aq ; soluble in HNO_3Aq , also in H_2SO_4 with a little water.

Reactions.—1. Gives off O when heated in air or in an indifferent gas; the final product of heating in N or CO_2 is UO_2 (Zimmermann, *A.* 232, 283).—2. Reduced to UO_2 by heating with hydrogen, carbon, sulphur, potassium, or sodium. 3. Heated in vapour of carbon disulphide $U_2O_3S_2$ is formed.—4. Heated with conc. sulphuric acid, or with hydrochloric acid to 180° – 200° , gives both uranous and uranyl sulphates, or chlorides; reacting as $UO_2 \cdot 2UO_3$ (*Z.*, *A.* 232, 287).—5. Silver nitrate solution is slowly reduced to Ag (Isambert, *C. R.* 80, 1087).

HYDRATE OF URANOSO-URANIC OXIDE. By adding NH_4Aq to UCl_4Aq and allowing the pp. to oxidise in the air, and drying *in vacuo* over H_2SO_4 , Rammelsberg (*P.* 55, 319) obtained a greenish-black solid which may have been a hydrate of U_3O_8 ; one determination of water only is given which agrees fairly with $U_3O_8 \cdot 6aq$.

URANIUM TRIOXIDE UO_3 . (*Uranic oxide.* *Uranic anhydride.* *Uranyl oxide* $(UO_3)_2O$.) Mol. w. not known. This oxide is obtained by carefully heating the hydrate $UO_3 \cdot H_2O$ (*v. infra*) to 800° (Ebelmen, *A. Ch.* [2] 5, 199); to 250° , temperature being gradually raised (Jacquelin, *Ph. C.* 1845. 193). The oxide is also formed by heating $UO_2 \cdot CO_2 \cdot 2(NH_4)_2CO_3$ to 300° (*E.*, l.c.). The preparation of UO_3 may be conducted by heating $UO_2(NO_3)_2$ in a Pt basin until decomposition begins, then transferring to glass tubes

and heating these in an oil-bath to 250° so long as acid fumes are given off.

UO_3 is a chamois-yellow powder. S.G. 5.02 to 5.26 (Brauner & Watts, *P. M.* [5] 11, 60). Ebelmen (l.c.) described UO_3 obtained by heating $UO_2 \cdot CO_2 \cdot 2(NH_4)_2CO_3$ as a sealing-wax-red powder. When UO_3 is heated to redness it gives off O and U_2O_3 remains (*E.*, l.c.; cf. Read, *C. J.* 65, 313 [1894]); the oxide seems to be somewhat volatile at the temperature of a porcelain oven (Elsner, *J.* 1866. 35).

UO_3 reacts with many acids as a basic oxide, but the salts formed are always basic salts of the forms $UX_{2n} \cdot 2UO_3$, where X = the radiole of a monobasic acid, and $UX_n \cdot 2UO_3$, where X = the radiole of a dibasic acid. It is customary to write the formulæ of these basic salts as $UO_2 \cdot X^1$, and $UO_2 \cdot X^2$, and to call them *uranyl salts*

$(UO_2 = \text{uranyl})$; thus $\frac{U(NO_3)_2 \cdot 2UO_3}{3} = UO_2(NO_3)_2$,

and $\frac{U(SO_4)_2 \cdot 2UO_3}{3} = UO_2(SO_4)$.

UO_3 behaves towards strong bases as an acidic oxide, forming uranates M_2UO_6 , and di-uranates $M_2U_2O_7$, &c.; these salts are generally formed by fusing U compounds with bases and O, and by ppg. uranyl salt solutions by strong bases. When $KOHAq$, $NaOHAq$, NH_4Aq , $BaOHAq$, or $CaOHAq$ is added to a solution of a uranyl salt, e.g. to $UO_2(NO_3)_2Aq$, the pp. consists of a uranate of the metal of the base. Alkali carbonates ppt. alkali uranates, but the pps. contain also CO_2 ; the pps. dissolve in excess of the alkali carbonates forming double carbonates of uranyl and the alkali metal, e.g. $UO_2 \cdot CO_2 \cdot 2(NH_4)_2CO_3$. Addition of alkali or alkali carbonate to solutions of uranyl salts containing other metallic salts causes ppn. of a uranate of the metal of the salt present, generally mixed with alkali uranate (*cf.* URANIUM OXYACIDS, AND SALTS THEREOF, p. 826).

By adding $KOHAq$ to a cold solution of UCl_4 or $UO_2(NO_3)_2$, and dialysing, Graham (*T.* 1861. 213) obtained a solution, free from acid and alkali, which he regarded as a loose compound of sugar and UO_3 , and which he called *sucrate of peroxide of uranium*.

HYDRATES OF URANIUM TRIOXIDE. Pure hydrates of UO_3 are not obtained by ppg. uranyl salt solutions by alkalis (*v. supra*); but according to Ebelmen (*A. Ch.* [3] 5, 199) $UO_3 \cdot xH_2O$ is produced by boiling an aqueous solution of $UO_2 \cdot CO_2 \cdot 2(NH_4)_2CO_3$ until a yellow pp. is formed, and allowing this pp. to stand for a long time. By the continued action of sunlight on $UO_3(C_2O_4)$ in presence of water, $UO_3 \cdot xH_2O$ is said to be formed; after washing and drying in the air, the solid has the composition $UO_3 \cdot 2H_2O$; and after drying *in vacuo* the composition is $UO_3 \cdot H_2O$ (*E.*, l.c.). Berzelius (*B. J.* 24, 118) obtained $UO_3 \cdot H_2O$ by heating $UO_2(NO_3)_2$ on a sand-bath until acid fumes ceased to be given off, washing the residue with boiling water, and drying in air. The same hydrate is said to be formed by heating UO_3 with $KClO_4$ until fusion begins, boiling out with water, and drying in air (Drenkmann, *J.* 1861. 256). The best method of preparing $UO_3 \cdot H_2O$ seems to be that given by Malaguti (*A. Ch.* [3] 9, 463), viz. boiling a solution of $UO_2(NO_3)_2$ in absolute alcohol as long as a

reaction proceeds, washing the yellow solid that separates with water, and drying in air or *in vacuo*; EtNO_3 , N_2O_5 , $\text{C}_2\text{H}_4\text{O}$, and $\text{H}_2\text{CO}_3\text{H}$ are formed in the reaction.

$\text{UO}_2\cdot\text{H}_2\text{O}$ is described as a yellow powder; S.G. 5.93 at 15° (Malaguti, *l.c.*); reddens litmus paper; when hot it absorbs CO_2 from the air; heated to 250° – 300° water is given off and UO_3 remains (Ebelmen, *l.c.*; Jacquelin, *A. Ch.* [3] 5, 199); heated to redness gives off O and leaves U_2O_5 . $\text{UO}_3\cdot\text{H}_2\text{O}$ is generally called *uranic acid*; *v.* URANIUM OXYACIDS, AND SALTS THEREOF (*infra*).

URANIUM PEROXIDE. By adding $\text{UO}_2(\text{NO}_3)_2\text{Aq}$ to a mixture of $\text{H}_2\text{O}_2\text{Aq}$ and a large excess of $\text{H}_2\text{SO}_4\text{Aq}$, and allowing to stand for a considerable time, Fairley (*C. J.* 31, 133 [1877]) obtained a small quantity of a heavy, crystalline, almost white pp., which when dried (? in air, or at 100°) had the composition UO_4 . By adding dilute $\text{H}_2\text{O}_2\text{Aq}$ to solution of $\text{UO}_2(\text{NO}_3)_2$ or $\text{UO}_2(\text{C}_2\text{H}_3\text{O}_2)_2$, free from acids, Fairley (*l.c.* p. 127) obtained a yellowish-white pp., which when dried by pressure between filter paper had the composition $\text{UO}_4\cdot 4\text{H}_2\text{O}$, and when dried at 100° the composition $\text{UO}_4\cdot 2\text{H}_2\text{O}$.

Zimmermann (*A.* 232, 273 [1886]) failed to obtain the tetrahydrate $\text{UO}_4\cdot 4\text{H}_2\text{O}$; according to him the dihydrate $\text{UO}_4\cdot 2\text{H}_2\text{O}$ is very hygroscopic, and begins to decompose at 115° . Alibegoff also obtained only $\text{UO}_4\cdot 2\text{H}_2\text{O}$; he failed to prepare the anhydrous oxide UO_4 (*A.* 233, 123 [1886]).

Hydrated uranium peroxide, dried at 100° , is a yellowish-white powder; decomposed by heat, giving off O and leaving much U_2O_5 ; reacts with alkali solutions to give $\text{UO}_3\cdot x\text{H}_2\text{O}$, and a solution from which alkali *peruranate* $2\text{M}_2\text{O}\cdot\text{UO}_4$, 8aq, crystallises (Fairley, *l.c.*; *v.* *Peruranates* under URANIUM OXYACIDS, AND SALTS THEREOF, p. 827).

URANIUM OXYACIDS, AND SALTS THEREOF. $\text{UO}_2\cdot\text{H}_2\text{O} = \text{H}_2\text{UO}_4$ reacts with strong bases as an acid, forming uranates M_2UO_4 ; di-uranates $\text{M}_2'\text{U}_2\text{O}_7$ are also known, and a few tri- and hexa-uranates. A few peruranates are derived from hydrated uranium peroxide $\text{UO}_3\cdot x\text{H}_2\text{O}$. The compounds of UO_2X_2 with MX ($\text{X} = \text{Br}, \text{Cl}, \text{or F}$) may be regarded as bromoxy-, chloroxy-, and fluoxy-uranates. The substance known as *uranium red* is perhaps $\text{UO}_3\cdot\text{ONH}_4\cdot\text{SNH}_4$, *i.e.* the ammonium salt of an oxythio-uranic acid (*v.* URANIUM OXYSULPHIDES, p. 828).

URANIC ACID H_2UO_4 . This compound is obtained as a yellow powder, which reddens litmus paper, and is decomposed to UO_3 and H_2O at 250° – 300° , and to U_2O_5 and O at a higher temperature, by boiling a solution of $\text{UO}_2(\text{NO}_3)_2$ in absolute alcohol, washing the solid that separates with water, and drying in air or *in vacuo*. (For other methods of preparation, and more details *v.* HYDRATES OF URANIUM TRIOXIDE, p. 825.) The salts of H_2UO_4 are prepared indirectly.

URANATES, DI-URANATES, &c. Salts derived from H_2UO_4 ; salts derived from the hypothetical acids $\text{H}_2\text{U}_2\text{O}_7$, $\text{H}_2\text{U}_3\text{O}_{10}$, $\text{H}_2\text{U}_4\text{O}_{13}$, are also known.

URANATES. Salts of the composition $\text{M}_2'\text{UO}_4$ and $\text{M}''\text{UO}_4$. These salts are prepared by ppg. solutions of uranyl salts by bases in solution, or by adding alkali solution to a mix-

ture of a uranyl salt and a metallic oxide in solution; also, in many cases, by oxidising U_3O_8 or UO_3 in presence of a base or a salt of a base. The uranates are insoluble in water, and are not readily decomposed by heat except the ammonium salt. Carson & Norton (*Am.* 10, 219) have pointed out that analyses of uranates always show considerable differences between the percentages of U found and calculated; they have found the same anomaly in analyses of uranates of ammonium and several ammonium derivatives, such as NEtH_4 , NEt_2H_4 , &c.

Ammonium uranates. The pure salt does not seem to have been isolated. An impure uranate containing c. 90 p.c. UO_3 ($(\text{NH}_4)_2\text{UO}_4$ requires 84.66 p.c. UO_3) is obtained by adding NH_4Aq to a solution of a uranyl salt (Péligot); it is a yellow powder, which loses H_2O and NH_3 above 100° , very slightly soluble in water, and insol. NH_4Aq (Arfvedson, *P.* 1, 245). An impure salt is also obtained by adding NH_4ClAq or $(\text{NH}_4)_2\text{SO}_4\text{Aq}$ to boiling $\text{Na}_2\text{UO}_4\text{Aq}$, as long as NH_3 and CO_2 are given off, washing the pp., and drying at a low temperature (Anthon, *D. P. J.* 156, 211). Heated to redness gives U_2O_5 ; many of the compounds of U are prepared from ammonium uranate.

Potassium uranate K_2UO_4 . Prepared by heating 6 g. U_3O_8 with HClAq and HNO_3Aq , adding 4 g. KCl and 16 g. NH_4Cl , evaporating to dryness, heating very strongly until the fused mass is orange-yellow, and washing with water (Zimmermann, *A.* 213, 290). The salt is said to be formed also by strongly heating UO_3HPO_4 (obtained by ppg. a uranyl salt by a phosphate) with K_2SO_4 (Grandeau, *A. Ch.* [6] 8, 223). Orange-yellow, rhombic tablets; insol. water, cold or hot; easily sol. acids (Zimmermann, *l.c.*).

Sodium uranate Na_2UO_4 . Prepared by fusing U_3O_8 with NaCl and Na_2CO_3 , or with NaCl with gradual addition of NaClO_3 , and washing with water; resembles K_2UO_4 (Zimmermann, *l.c.*).

Lithium uranate Li_2UO_4 has been prepared similarly to K_2UO_4 ; it is said to be decomposed by hot water (*Z.*, *l.c.*). Uranates of Ba, Ca, and Sr— MUO_4 —are said by Ditte (*C. R.* 95, 989) to be formed by heating the chlorides of these metals with U_3O_8 .

DI-URANATES. Salts of the composition $\text{M}_2'\text{U}_2\text{O}_7$ and $\text{M}''\text{U}_2\text{O}_7$. The formulae may also be written $\text{M}_2'\text{UO}_4\cdot\text{UO}_3$ and $\text{M}''\text{UO}_4\cdot\text{UO}_3$.

Barium di-uranate BaU_2O_7 . Formed by ppg. $\text{UO}_2(\text{C}_2\text{H}_3\text{O}_2)_2\text{Aq}$ by BaO_2Aq (Berzelius, *P.* 1, 359); also by heating to redness $\text{UO}_3\cdot\text{Ba}(\text{C}_2\text{H}_3\text{O}_2)_2$ (Wertheim, *J. pr.* 29, 207). A yellowish-red powder.

Calcium di-uranate CaU_2O_7 . Formed, according to Ditte (*C. R.* 95, 988), by strongly heating U_3O_8 with $\text{Ca}(\text{ClO}_3)_2$; a yellowish-green solid.

Copper di-uranate CuU_2O_7 . This salt is said to be formed, as a green crystalline powder, by fusing $\text{Cu}(\text{UO}_2\text{PO}_4)_2$, 8aq with Na_2CO_3 , and washing with water (Debray, *A. Ch.* [3] 61, 451).

Lead di-uranate PbU_2O_7 . Formed by digesting $\text{UO}_2(\text{C}_2\text{H}_3\text{O}_2)_2\text{Aq}$ with freshly ppg. PbCO_3 (Wertheim, *J. pr.* 29, 207); also by adding NH_4Aq to a mixture of $\text{UO}_2(\text{NO}_3)_2\text{Aq}$ and $\text{Pb}(\text{NO}_3)_2\text{Aq}$ (Arfvedson, *P.* 1, 258). A yellowish-

red powder, becoming green when heated; strongly heated in H, gives a pyrophoric mixture of Pb and UO_2 .

Potassium di-uranate K_2UO_4 . Formed by melting together UO_3 and K_2CO_3 and washing with water; also by strongly heating $\text{UO}_2 \cdot \text{K}_2(\text{CO}_3)_2$ or $\text{UO}_2 \cdot \text{K}(\text{C}_2\text{H}_3\text{O}_2)_2$ (Berzelius, *P.* 1, 359). A yellowish-red powder.

Silver di-uranate Ag_2UO_4 . Obtained by adding amorphous K_2UO_4 to molten AgNO_3 , and washing with ice-cold water (Alibegoff, *A.* 232, 129; 233, 117, 143). Also by strongly heating $\text{UO}_2 \cdot \text{Ag}(\text{C}_2\text{H}_3\text{O}_2)_2$ (Wertheim, *J. pr.* 29, 221; cf. Rammelsberg, *P.* 59, 10). An amorphous, yellow-red solid; easily sol. acids; decomposed by hot water (Alibegoff, *l.c.*).

Sodium di-uranate Na_2UO_4 . 6aq. Obtained by ppg. uranyl salts by NaOHAq (Patera, *J. pr.* 51, 125; cf. Stolba, *Fr.* 3, 74). Loses water of crystallisation over H_2SO_4 . A light-yellow to darkish-yellow powder. Known commercially as *uranium yellow* (v. DICTIONARY OF APPLIED CHEMISTRY, vol. iii. p. 893).

Di-uranate of strontium SrU_2O_7 , is said also to exist (Ditte, *C. R.* 95, 988).

TRI-URANATES. The only salt that has been isolated is *sodium tri-uranate* $\text{Na}_3\text{U}_2\text{O}_{10}$; it is prepared by fusing $\text{UO}_2(\text{SO}_4)$ with NaCl , and boiling out with water. This salt forms yellow leaflets resembling mosaic gold; S.G. 6.912; hygroscopic; insol. water, sol. acids (Drenkmann, *J.* 1861. 255).

HEXA-URANATES. The *potassium salt*, $\text{K}_6\text{U}_3\text{O}_{18}$, 6aq, is described as a yellow microscopically crystalline powder, which loses all water at $300^\circ\text{--}400^\circ$; prepared by melting $\text{UO}_2(\text{SO}_4)$ with KCl (Drenkmann, *J.* 1861. 255).

PER-URANATES. By adding excess of alkali and $\text{H}_2\text{O}_2\text{Aq}$ to solutions of uranyl salts, Fairley (*C. J.* 31, 184) obtained salts which may be formulated as M^+UO_4 . 2aq and $\text{M}^+\text{R}^+\text{UO}_4$. 2aq where $\text{M} = \text{NH}_4$, K , or Na , and $\text{R} = \text{UO}_2$.

Ammonium-uranyl peruranate $(\text{NH}_4)_2(\text{UO}_2)_3\text{O}_{10}$. 8aq. The formula may also be written $(\text{NH}_4)_2\text{O} \cdot \text{UO}_4$. 8aq, or $(\text{NH}_4)_2\text{O} \cdot \text{UO}_2 \cdot \text{UO}_4$. 8aq, or, regarding the compound as a double peroxide of U and NH_4 , as $2\text{UO}_2(\text{NH}_4)_2\text{O}_4$. 8aq. The salt is prepared by adding excess of NH_4Aq and $\text{H}_2\text{O}_2\text{Aq}$ to a solution of a uranyl salt and ppg. by alcohol; it is an orange-yellow solid, readily soluble in water. The quantity of KMnO_4 in solution decolourised shows that the ratio of U to 'peroxide oxygen' in the salt is U:3O.

Potassium per-uranate K_4UO_6 . 10aq. This salt may also be looked on as a double peroxide of U and K ($\text{UO}_2 \cdot \text{K}_2\text{O}_4$. 10aq), or as $2\text{K}_2\text{O} \cdot \text{UO}_4$. 10aq. It is prepared by adding alcohol to a solution obtained by treating $\text{UO}_2(\text{NO}_3)_2\text{Aq}$ with KOH Aq and excess of $\text{H}_2\text{O}_2\text{Aq}$, and rapidly drying the orange-yellow pp. by pressure in filter paper. The salt rapidly absorbs CO_2 from the air and loses O; it is easily decomposed by heat, giving off H_2O and O. Experiments showed that the ratio of U to 'peroxide oxygen' is U:3O.

Sodium peruranate Na_4UO_6 . 8aq. The formula may also be written $\text{UO}_2 \cdot \text{Na}_2\text{O}_4$. 8aq or $2\text{Na}_2\text{O} \cdot \text{UO}_4$. 8aq. The salt is prepared by dissolving 'ordinary uranic hydrate,' or UO_3 . 2aq, in excess of NaOHAq along with excess of $\text{H}_2\text{O}_2\text{Aq}$, allowing to crystallise if conc. solutions

are used, or ppg. by a little alcohol if dilute solutions are used, and drying by pressure in filter paper. Poleck (*B.* 27, 1051 [1894]) obtained this salt by adding sodium superoxide to solution of a salt of U. The salt is golden-yellow and lustrous; it slowly absorbs CO_2 from the air, and gives off O. When heated, alone or in CO_2 , it gives off 3O; it also loses 3O in contact with acidified KMnO_4Aq or other unstable O compounds. The ratio of U to 'peroxide oxygen' is U:3O as measured by the quantity of KMnO_4 decolourised by a solution of the salt.

Sodium-uranyl per-uranate

$\text{Na}_2(\text{UO}_2)_3\text{O}_{10}$. 6aq. The formula may also be written $\text{Na}_2\text{O} \cdot \text{U}_3\text{O}_{10}$. 6aq or $\text{Na}_2\text{O} \cdot \text{UO}_4 \cdot \text{UO}_4$. 6aq; or, regarding the compound as a double peroxide of U and Na, as $2\text{UO}_2 \cdot \text{Na}_2\text{O}_4$. 6aq. The salt is prepared similarly to Na_2UO_4 . 8aq, but using only the minimum quantity of NaOHAq required for solution, and adding alcohol, when it separates as a red oil which slowly crystallises to a red solid. The quantity of KMnO_4 in solution decolourised by a solution of the salt showed that the ratio of U to 'peroxide oxygen' is U:3O.

Uranium, oxybromide of, UO_2Br_2 . (*Uranyl bromide*.) In preparing UBr_3 , by heating a mixture of U_3O_8 and C in Br vapour, Hermann (*J.* 1861. 260) obtained a yellow, easily volatile sublimate, which was probably an oxybromide. By heating UO_2 with Br and water, also by dissolving UO_3 in HBr Aq , a colourless liquid is obtained, which on evaporation gives yellow needles of the *hydrated oxybromide* $\text{UO}_2\text{Br}_2 \cdot 7\text{aq}$ (Sendtner, *A.* 195, 325). This compound combines with NH_4Br and KBr to form $\text{UO}_2\text{Br}_2 \cdot 2\text{MBr}$ (v. URANOXYBROMIDES, p. 822).

Uranium, oxychloride of, UO_2Cl_2 . (*Uranyl chloride*.) Formed by strongly heating UO_3 in Cl; a yellow, crystalline solid, easily fused, but volatilised only at a high temperature; heated with K forms UO_2 and KCl (Péligot, *A. Ch.* [3] 5, 5). By dissolving $\text{UO}_3 \cdot \text{H}_2\text{O}$ in HCl Aq , also by oxidising UCl_4 by HNO_3Aq , and evaporating, yellowish-green crystals of $\text{UO}_2\text{Cl}_2 \cdot x\text{H}_2\text{O}$ are obtained (Klaproth, *Crell's A.* 1789 [2]. 387).

By dissolving UO_2Cl_2 in ether and evaporating, Regelsberger (*A.* 227, 119) obtained yellow needles of the compound $\text{UO}_2\text{Cl}_2 \cdot 2\text{EtO}$.

UO_2Cl_2 forms compounds with NH_4Cl and KCl of the form $2\text{MCl} \cdot \text{UO}_2\text{Cl}_2$ (v. URANOXYCHLORIDES, p. 823).

UO_2Cl_2 combines with NH_3 to form $\text{UO}_2\text{Cl}_2 \cdot x\text{NH}_3$, where $x = 2, 3$, and 4. The first of these compounds, $\text{UO}_2\text{Cl}_2 \cdot 2\text{NH}_3$, is formed by passing dry NH_3 into UO_2Cl_2 dissolved in ether, drying the voluminous yellow pp. that forms, and then placing it *in vacuo* over H_2SO_4 , until all ether is removed; the second compound, $\text{UO}_2\text{Cl}_2 \cdot 3\text{NH}_3$, is formed by the action of NH_3 on $\text{UO}_2\text{Cl}_2 \cdot 2\text{NH}_3$; and a mixture of $\text{UO}_2\text{Cl}_2 \cdot 3\text{NH}_3$ and $\text{UO}_2\text{Cl}_2 \cdot 4\text{NH}_3$ is produced by passing NH_3 over solid UO_2Cl_2 . When strongly heated in air these compounds give off all NH_3 and Cl and leave U_3O_8 ; heated out of contact with air they give UO_2 (Regelsberger, *A.* 227, 119). The three compounds are called by R. *uranylammonium chlorides*, and their formulas are written $\text{UO}_2(\text{NH}_4\text{Cl})_2$, $\text{UO}_2(\text{NH}_4\text{Cl})(\text{NH}_3 \cdot \text{NH}_4\text{Cl})$, and $\text{UO}_2(\text{NH}_3 \cdot \text{NH}_4\text{Cl})_2$. Water reacts thus:—
(1) $3\text{UO}_2(\text{NH}_4\text{Cl})_2 + 8\text{H}_2\text{O} = (\text{NH}_4)_2\text{U}_3\text{O}_{10} + \text{UO}_2\text{Cl}_2 + 4\text{NH}_4\text{Cl}$;

(2) $\text{UO}_2(\text{NH}_4\text{Cl})_2 + 2\text{H}_2\text{O} = \text{UO}_2(\text{OH})_2 + 2\text{NH}_4\text{Cl}$; the second reaction takes place quickly with warm water.

Uranium, oxyfluoride of, UO_2F_2 . (*Uranyl fluoride*.) This compound is produced by boiling U_3O_8 with HFAq , filtering off UF_4 (v. URANIUM TETRAFLUORIDE, p. 823), and evaporating the filtrate; it is also formed, in small quantities, by heating UF_4 in a closed Pt crucible. The compound differs according to the method of preparation (Smithells, *C. J.* 43, 125).

α -Oxyfluoride. About 1 gram UF_4 is heated in a Pt crucible with the lid on, temperature being raised as quickly as possible; after five minutes the crucible is allowed to cool, the light, bulky sublimate is removed, and the crucible is again heated for five minutes, and these processes are repeated several times (*S., l.c.* p. 129). This form of UO_2F_2 is a very bulky, light, white, crystalline solid; it is very soluble in water, forming a yellow liquid; heated in air it is gradually changed to U_3O_8 .

β -Oxyfluoride. U_3O_8 is treated with boiling HFAq in a leaden vessel, the yellow solution is poured off from green UF_4 , heated until the excess of HF is driven off, and allowed to evaporate; evaporation may be completed over H_2SO_4 and CaO *in vacuo*; the residue is dried at 100° (*S., l.c.* p. 130). This form of UO_2F_2 is a yellow saponaceous mass; in one instance the preparation had a semi-crystalline appearance, forming yellow, lustrous scales; it is very soluble in water or alcohol; heated on Pt foil U_3O_8 is formed; heated in a closed crucible it is slowly decomposed, giving UO_2 . $\beta\text{-UO}_2\text{F}_2$ probably forms a compound with HF ; by evaporating a solution of U_3O_8 in HFAq over H_2SO_4 and CaO until the weight was constant, Smithells (*l.c.* p. 131) obtained a substance which gave results on analyses agreeing fairly with the formula $\text{UO}_2\text{F}_2 \cdot \text{HF} \cdot \text{H}_2\text{O}$.

A solution in water of either form of UO_2F_2 mixed with KFAq and KHF_2Aq , and evaporated, gives the quadratic fluoxy-uranate $\text{K}_2\text{UO}_2\text{F}_6$ (*S., l.c.* p. 130-1). For the compounds of UO_2F_2 with MF v. URANOXYFLUORIDES (p. 824).

Ditte (*C. R.* 91, 115) gave the formula UOF_4 to the sublimate obtained by heating, in a closed Pt crucible, the solid that remained when U_3O_8 was treated with boiling HFAq . Ditte said that this solid was UO_2F_2 ; Smithells (*l.c.*) has, however, shown that the solid obtained by the method used by Ditte is UF_4 , and that the sublimate formed by heating this is $\alpha\text{-UO}_2\text{F}_2$.

Uranium, oxysulphides of. Two compounds probably exist.

URANIUM OXYSULPHIDE $\text{U}_3\text{O}_2\text{S}_2$. This composition was given by Hermann (*J.* 1861. 258) to a dark, greyish-black solid, obtained by heating UO_2 , U_3O_8 , or NH_4 uranate to redness in vapour of CS_2 . Dissolves in conc. HClAq ; burns when heated in air (*cf.* H. Rose, *G. A.* 73, 139).

URANYL SULPHIDE $(\text{UO}_2)_2\text{S}$. A brown solid, obtained by ppg. an ammoniacal solution of a uranyl salt by cold $(\text{NH}_4)_2\text{SAq}$, and quickly washing with conc. alcohol. Probably not obtained pure, as it quickly decomposes; water produces $\text{UO}_2 \cdot \text{H}_2\text{O}$; at 40° - 50° it is changed to UO_2 and S (Remelé, *P.* 124, 114; Zimmermann, *A.* 204, 204). $(\text{UO}_2)_2\text{S}$ is somewhat sol. water or dilute alcohol: dissolved by conc. HClAq , giving UCl_4

and S; dissolved by $(\text{NH}_4)_2\text{SAq}$, only in presence of $(\text{NH}_4)_2\text{CO}_3\text{Aq}$ (Zimmermann, *l.c.*), forming a brown liquid.

Uranium black. By allowing $(\text{UO}_2)_2\text{S}$ to stand in contact with freshly prepared $(\text{NH}_4)_2\text{SAq}$, in absence of air, a dull black amorphous powder is obtained. This solid dissolves in mineral acids, giving off traces of H_2S ; it dissolves partly in warm $(\text{NH}_4)_2\text{CO}_3\text{Aq}$, but not in warm $(\text{NH}_4)_2\text{SAq}$, nor in caustic alkali solutions; heated in a tube to $c. 270^\circ$ it gives off a very little NH_3 and H_2O . Zimmermann (*A.* 204, 204) gives the formula U_3O_8 to uranium black, neglecting (as impurities) the traces of NH_3 and S which the substance contains.

Uranium red. By allowing $(\text{UO}_2)_2\text{S}$ to stand for 24-48 hours in contact with cold $(\text{NH}_4)_2\text{SAq}$, exposed to air, a deep-red solid is obtained; soluble in dilute mineral acids, with separation of S and evolution of H_2S ; gives off NH_3 , S, and H_2O when heated to 150° and, at above 200° , leaves U_3O_8 (Zimmermann, *l.c.*). According to Z., the formation of this red substance takes place only when $(\text{NH}_4)_2\text{S}_2\text{O}_8$ is present in the $(\text{NH}_4)_2\text{SAq}$ used; $(\text{NH}_4)_2\text{S}_2\text{O}_8$ is formed by the action of the air. Z. gives to uranium red the composition $\text{U}_3\text{S}(\text{NH}_4)_2\text{O}_6 = \text{UO}_2 \cdot \text{ONH}_4 \cdot \text{SNH}_4 \cdot 2\text{U}_2\text{O}_3$ (*cf.* Patera, *J. pr.* 51, 122; Remelé, *P.* 124, 158; Hermann, *J.* 1861. 14).

Uranium, salts of. Two classes of salts are formed by treating oxides of U with acids; UO_2 forms corresponding salts, UX_2 , when X = the radicle of a dibasic acid, and UX , when X = the radicle of a monobasic acid; UO_3 forms salts $(\text{UO}_2)_2\text{X}$ when X = the radicle of a dibasic acid, and $(\text{UO}_2)_2\text{X}_2$ when X = the radicle of a monobasic acid. The salts UX^{I} , and UX^{II} , are called *uranous salts*; and $(\text{UO}_2)_2\text{X}_2$ and $(\text{UO}_2)_2\text{X}^{\text{II}}$ are called *uranyl salts*. (For reactions of the two classes of salts v. URANIUM, *Detection and estimation of*, p. 822.) Besides the normal salts, a large number of basic salts of both classes is known, and also many double salts.

The chief *uranous salts* are *arsenates, phosphates, and sulphites*. The chief *uranyl salts* are *arsenates, bromates, double carbonates, chromates, hypophosphite, iodate, nitrates, ozalate, phosphates, phosphite, selenates, selenites, sulphates, and sulphites* (v. NITRATES, SULPHATES, &c.).

Uranium, sulphides of. When U is burnt in vapour of S, the disulphide US_2 is formed; by passing H_2S over heated UBr_2 the sesquisulphide U_2S_3 is produced; and by heating U_3S_8 in H the monosulphide US is obtained. The mol. w. of none of these is known.

URANIUM DISULPHIDE US_2 . Prepared by heating U in vapour of S (Péligot, *P.* 54, 122; *cf.* Zimmermann, *A.* 216, 18); also by heating UCl_4 to redness in H_2S (Hermann, *J.* 1861. 258). A dark greyish-black powder; becomes crystalline when fused with borax; oxidises slowly in air, rapidly on heating. Easily soluble in conc. HClAq (Hermann, *l.c.*).

URANIUM SESQUISULPHIDE U_2S_3 . A stream of dry H_2S , perfectly free from air, is passed over heated UBr_2 , as long as HBr is given off. Grey-black solid, forming pseudomorphs of UBr_2 ; decomposes in air, giving off H_2S ; burns when heated in air; scarcely acted on by HClAq or

dilute HNO_3 ; decomposed violently by conc. HNO_3 (Alibegoff, *A.* 233, 117).

URANIUM MONOSULPHIDE *US.* A black, amorphous powder; obtained by passing dry H_2 over U_2S_5 , kept at a red heat, for c. 40 hours, until H_2S is no longer given off. Similar in properties to U_2S_5 (Alibegoff, *A.* 233, 135).

Uranium thio-acids, salts of. No thio-acid, nor salt of a thio-acid, of U has been definitely isolated. *Uranium red* (*v. supra*, p. 828) may perhaps be an ammonium oxythionate of U .

URANIUM TETRACHLORIDE.

URANOXYFLUORIDES *v.* p. 824, under

URANIUM TETRAFLUORIDE.

URANYL COMPOUNDS, compounds of the radicle UO_2 ; *v.* **URANYL AMMONIUM CHLORIDES** (p. 827), **URANYL BROMIDE** (p. 827), **URANYL CHLORIDE** (p. 827), **URANYL FLUORIDE** (p. 828), **URANYL SALTS** (p. 828), **URANYL SULPHIDE** (p. 828).

URAZOLE. A name given by Pinner (*B.* 20, 2358) to di-oxy-triazole, which may be represented as $\text{NH}_2\text{C}(\text{OH})\text{N}=\text{N}\text{CO}$ or $\text{NH}_2\text{CO}\text{N}=\text{N}\text{CO}$.

UREA $\text{CH}_4\text{N}_2\text{O}$, *i.e.* $\text{CO}(\text{NH}_2)_2$. *Carbamide.* Mol. w. 60. [132°] (Lubavin, *B.* 3, 305). S.G. 1.323 (Schröder, *B.* 12, 562). S. (alcohol) 20 in the cold; 100 at 78°. H.C.v. 152,500. H.C.p. 152,200 (Stohmann & Langbein, *J. pr.* [2] 44, 387); 160,900 (Berthelot & Petit, *C. R.* 109, 759; 110, 887). H.F. 80,800.

Occurrence.—In the urine of mammalia, especially in that of flesh-eaters (Fourcroy & Vauquelin, *A. D.* 1799). Occurs in small quantity in blood, muscle, chyle, and lymph of mammalia (Wurtz, *C. R.* 49, 52; Poisseuille & Gobley, *J.* 1859, 612; Verdel & Dollfus, *A.* 74, 214; Munk, *Pf.* 11, 100; Pickard, *C. R.* 83, 1179; 87, 533; Gréhan & Quinquand, *C. R.* 108, 1092; Garrod, *Pr.* 53, 478). Constitutes about 30 p.c. of the solid substance of the vitreous humour of the eye (Millon, *C. R.* 26, 119; *A.* 66, 128). Occurs also in saliva (Rabuteau, *J.* 1873, 877), in cow's milk (Lefort, *Z.* 1866, 190; Vogel, *J.* 1867, 932), and in other animal secretions.

Formation.—1. By evaporating a solution of ammonium cyanate (Liebig & Wöhler [1828], *B.* 12, 266; *P.* 12, 253; 15, 619; *A.* 38, 108). 2. By adding a little NHO_3 to an ethereal solution of cyanamide (Cannizzaro & Cloëz, *A.* 78, 230) or by the action of dilute (50 p.c.) H_2SO_4 on cyanamide (Baumann, *B.* 6, 1373).—3. From COCl_2 and dry NH_3 (Regnault, *A. Ch.* [2] 69, 180; Natanson, *A.* 98, 287), guanidine and NH_4Cl being formed at the same time (Fenton, *C. J.* 35, 793).—4. By heating carbonic ether with NH_3 at 180°.—5. By heating ammonium carbamate at 140° (Basaroff, *J. pr.* [2] 1, 283).—6. By passing an alternating electric current through a solution of ammonium carbamate (Drechsel, *J. pr.* [2] 22, 481).—7. By electrolysis of ammonia solution, using carbon electrodes (Millet, *Bl.* [2] 46, 243).—8. By passing a mixture of NH_3 and CO through a red-hot tube (Dexter, *Am. J.* 35).—9. Formed by passing air charged with NH_3 and vapour of benzene over a red-hot helix of platinum wire (Herroun, *C. J.*

39, 471). Acetylene, but not ethylene, may be substituted for benzene.—10. By heating ammonium thiocarbamate $\text{NH}_2\text{CO.SNH}_2$, or by shaking it with water and PbCO_3 .—11. By the action of aqueous KMnO_4 on thio-urea (Maly, *M.* 11, 277).—12. By the action of KMnO_4 on KCy in acid solution (Baudrimont, *J.* 1880, 393).—13. By the action of NH_4Aq and H_2S on copper fulminate (Gladstone, *A.* 66, 2).—14. By heating oxamide with HgO (Williamson, *Mémoires du Congrès scientif. de Venise*, A.D. 1847).—15. By oxidation of uric acid.—16. By the action of KClO_3 and HCl on guanine (Strecker, *A.* 118, 159).—17. By boiling guanidine with baryta (Baumann, *B.* 6, 1376).—18. By boiling biguanide sulphate or phenyl-biguanide sulphate with baryta (Emich, *M.* 12, 11).—19. By the action of baryta on arginin (Schulze & Likiernik, *B.* 24, 2701).—20. By boiling creatin with baryta.—21. A product of oxidation of proteids by KMnO_4 (Béchamp, *A. Ch.* [3] 48, 348; *C. R.* 70, 866; Ritter, *Bl.* [2] 16, 32). Stædeler (*J. pr.* 72, 251) and Loew (*J. pr.* [2] 2, 289) failed to obtain urea in this manner. Dreschel (*B.* 23, 3097) obtained urea from albumen by electrolysis, but not by oxidation.

Preparation.—1. Urine, concentrated by evaporation, is treated with nitric or oxalic acid, and the ppd. nitrate or oxalate of urea is decomposed by CaCO_3 .—2. A solution of potassium cyanate mixed with ammonium sulphate is evaporated on a water-bath to dryness, and the residue extracted with alcohol.—3. A mixture of dry K_2FeCy_4 (28 pts.) and MnO_2 (14 pts.) is heated till sticky on an iron plate. A cold aqueous extract of the mass is mixed with $(\text{NH}_4)_2\text{SO}_4$ (20.5 pts.), evaporated to dryness, and extracted with alcohol (Liebig).—4. Dry K_2FeCy_4 (8 pts.) is fused with K_2CO_3 (3 pts.) and PbO (15 pts.) added to the melted mass. The cooled mixture is dissolved in water, mixed with $(\text{NH}_4)_2\text{SO}_4$ (8 pts.) evaporated, and extracted with alcohol (Clemm, *A.* 66, 382). Any K_2FeCy_4 left can be removed by FeSO_4 .—5. Lead cyanate is digested with $(\text{NH}_4)_2\text{SO}_4$ (J. Williams, *C. J.* 21, 64).—6. From NH_4Aq , COS , and lead carbonate (Schmidt, *B.* 10, 193).—7. By the action of $(\text{NH}_4)_2\text{SO}_4$ on KCyO obtained by heating dry K_2FeCy_4 with $\text{K}_2\text{Cr}_2\text{O}_7$; the yield being 25 p.c. of the weight of ferrocyanide (C. A. Bell, *C. N.* 32, 99).—8. A stream of dry NH_3 gas is passed through phenyl-carbonate (from phenol-sodium and COCl_2), melted in a water-bath, and the melt is then poured into hot water; the aqueous solution after separation from the phenol is evaporated to crystallisation (Hentschel, *B.* 17, 1286).

Properties.—Dimetric crystals, *v. e.* sol. water, *m. sol.* cold alcohol, insol. CHCl_3 , nearly insol. ether. Sublimes at 130°. *In vacuo* it distils at 135° (Bourgeois, *Bl.* [3] 7, 45). Urea is not attacked by pure HNO_3 (Franchimont, *R. T. C.* 6, 217).

Reactions.—1. When heated alone at 150°–170° it yields NH_3 , cyanuric acid and biuret; at 140° it yields ammeline.—2. Decomposed into CO_2 and NH_3 by heating with water in sealed tubes above 100°, by boiling with potash, lime, or magnesia, by warming with conc. H_2SO_4 , by evaporating with lead acetate, and by the action of ozone (Gorup-Besanez, *A.* 125, 207).

in presence of free alkali. CaO produces cyanamide (Emich, M. 10, 330). A 3 p.c. HCl solution decomposes 4 p.c. of the urea in 24 hours. NaOH aq. of the same strength has less effect. Cold water does not decompose urea (Berthelot a. André, *Bl.* [2] 47, 840).—3. *Alcoholic potash* forms, on heating in sealed tubes, cyanic acid, NH_3 , and water (Haller, *Bl.* [2] 45, 705).—4. Urea hydrochloride at 145° yields NH_4Cl and cyanuric acid (De Vry, A. 61, 249).—5. *Chlorine* passed over melted urea forms HCl, nitrogen, NH_4Cl , and cyanuric acid (Wurtz, A. 64, 307).—6. *Hypochlorous acid, hypochlorites, chlorine-water, and hypobromites*, set free nitrogen, e.g. $\text{CON}_2\text{H}_4 + 3\text{HOCl} = \text{CO}_2 + 3\text{HCl} + 2\text{H}_2\text{O} + \text{N}_2$.—7. *Nitrous acid* added to a hot solution forms CO_2 and nitrogen: $\text{CON}_2\text{H}_4 + \text{N}_2\text{O}_3 = \text{CO}_2 + 2\text{H}_2\text{O} + 2\text{N}_2$. Nitrous acid (2 mols.) when added to a cold solution of urea (1 mol.) reacts as follows: $2\text{CON}_2\text{H}_4 + \text{N}_2\text{O}_3 = (\text{NH}_4)_2\text{CO}_3 + 2\text{N}_2 + \text{CO}_2$ (Claus, B. 4, 140).—8. Neutral KMnO_4 has no action in the cold, and acts but slowly at 100° . In acid solutions KMnO_4 gives off nitrogen (1 vol.) and CO_2 (2 vols.) (Béchamp, J. 1856, 696; cf. Wanklyn a. Gamgee, C. J. 21, 25).—9. *Bromine* added gradually to an alcoholic solution of urea forms NH_4Br , cyanuric acid, and nitrogen. In sealed tubes Br gives NH_4Br and cyanamide (Smolka, M. 8, 64).—10. Heating with P_2O_5 forms cyanic and cyanuric acids, ammeline, cyanamide, and NH_3 (Weltzien, A. 107, 219).—11. Yields cyanamide on warming with Na (Fenton, C. J. 41, 262).—12. Conc. HNO_3 reacts thus: $\text{CON}_2\text{H}_4 + 2\text{HNO}_3 = \text{CO}_2 + \text{N}_2\text{O} + \text{NH}_4\text{NO}_3 + \text{H}_2\text{O}$ (Franchimont, R. T. C. 2, 96; 3, 219).—13. P_2S_5 forms crystalline $\text{C}_2\text{H}_4\text{N}_2\text{PS}_2\text{O}_2$, which yields $\text{C}_2\text{H}_4\text{AgN}_2\text{PS}_2\text{O}_2$ and $\text{C}_2\text{H}_4\text{Ag}_2\text{N}_2\text{PS}_2\text{O}_2$, and gives off PH_3 on warming (Kutschig, M. 9, 406).—14. *Zinc-dust* at a red heat forms ZnCy_2 , ammonia, and hydrogen (Aufschläger, M. 13, 272).—15. CS_2 at 100° forms COS and ammonium sulphocyanide. With alcohol and CS_2 the products are mercaptan, CO_2 , and ammonium sulphocyanide (Ladenburg, Z. [2] 5, 253; B. 1, 273; 2, 271; Fleury, A. 123, 144).—16. *Alcohols* in sealed tubes form carbamic ethers and alkyl allophanates (Cabours, C. R. 76, 1387).—17. Boiling Ac_2O forms acetamide and diacetamide (Hofmann, B. 14, 2733).—18. ZnEt_2 forms $\text{CON}_2\text{H}_2\text{Zn}$, which is reconverted into urea by water (Gal, *Bl.* [2] 39, 648).—19. *Oxalic ether* at 135° – 170° forms oxamide, allophanic ether, and alcohol (Grabowski, A. 134, 115). *Oxamic ether* forms, on fusion, oxaluramide (Carstanjen, J. pr. [2] 9, 143).—20. *Methylamido-acetic acid* (sarcosine) forms methyl-hydantoin on fusion (Huppert, B. 6, 1278).—21. *Aniline* at 150° – 170° gives NH_3 and di-phenyl-urea (Baeyer, A. 131, 251).—22. *Aniline sulphonic acid* at 120° gives NH_3 , CO_2 , $\text{NH}_4\text{C}_6\text{H}_4\text{SO}_3\text{H}$ (Ville, *Bl.* [3] 6, 6).—23. *Biquanide sulphate* forms, on heating, ammeline, NH_3 , and $(\text{NH}_4)_2\text{SO}_4$ (Smolka a. Friedreich, M. 10, 96).—24. Heated with *acetone* and ZnCl_2 or P_2O_5 at 110° – 140° it gives s-t-l-methylpyridine and a base $\text{C}_8\text{H}_9\text{N}$ [119°] (320°) (Riehm, A. 238, 22). This base forms hard monoclinic crystals, with metallic ring; its solutions fluoresce. It gives $\text{B}_2\text{H}_3\text{PtCl}_4$ [225°].—25. Heated with *acetyl-acetone* (1 mol.), urea (2 mols.) forms $\text{CH}_2(\text{CMe:N.CO.NH}_2)_2$, which crystallises from alcohol [200°] (Combes, *Bl.* [3]

7, 790). The same body is formed, together with $\text{CH}_2\langle\text{CMe:N.CO.NH}_2\rangle\text{CO}$ [198°], by adding HCl aq or H_2SO_4 to an alcoholic solution of urea and acetyl-acetone (Evans, J. pr. [2] 46, 352; 48, 499).—26. *Benzoyl-acetone* forms, in like manner, $\text{Bz.CH}_2\text{CMe:N.CO.NH}_2$ [191°] and $\text{CH}_2\langle\text{CMe:N.CO.NH}_2\rangle\text{CO}$ [227°] (Evans, J. pr. [2] 46, 352; 48, 509).—27. *Acetoacetic ether* (2 mols.) and NaOEt (2 mols.) form in the cold $\text{C}_6\text{H}_5\text{H}_2\text{N}_2\text{O}_2\text{Na}_2$ [c. 165°] (Ernert, A. 258, 361). Acetoacetic ether in alcoholic solution forms uramido-crotonic acid (q. v.).—28. Urea reacts with aldehydes in the cold. In aqueous solution a diureide $\text{R.CH}(\text{NH.CO.NH}_2)_2$ is usually formed, while solid urea forms triureides. On warming with excess of aldehyde, di- and tri-ureides yield tetra- and hexa-ureides (H. Schiff, A. 161, 186). These ureides are sparingly soluble neutral solids, and are split up by warming with acids into the parent substances. Benzoic aldehyde forms benzylidene-di-urea (q. v.), while o-xy-benzoic aldehyde forms $\text{C}_6\text{H}_4(\text{OH}).\text{CH}(\text{NH.CO.NH}_2)_2\text{aq}$, which is converted by acetoacetic ether in alcohol into $\text{C}_6\text{H}_4(\text{OH}).\text{CH:N.CO.NH.CO.NH.CMe.CH}_2\text{CO}_2\text{Et}$ [200°], $\text{C}_6\text{H}_4(\text{OH}).\text{CH:N.CO.NH.CMe.CH}_2\text{CO}_2\text{Et}$ [204°], and $\text{C}_6\text{H}_4\langle\text{O.CH:N.CO.O.CH:CMe}\rangle\text{NH}$, which decomposes between 260° and 270° (Biginelli, B. 24, 2963). Acrolein forms $(\text{CON}_2\text{H}_4)_3\text{C}_2\text{H}_3\text{O}$, which chars at 250° (Lüdy, M. 10, 295). o-Nitro-benzoic aldehyde forms nitro-benzylidene-di-urea $\text{C}_6\text{H}_4(\text{NO}_2).\text{CH}(\text{NH.CO.NH}_2)_2\text{aq}$ [200°]. In like manner cumic aldehyde in alcohol forms the di-ureide $\text{C}_6\text{H}_5.\text{C}_6\text{H}_4.\text{CH}(\text{NH.CO.NH}_2)_2$ [176°] (Biginelli, B. 24, 2964), and cinnamic aldehyde forms $\text{Ph.CH.CH.CH}(\text{NH.CO.NH}_2)_2$ [172°], and compounds melting at 116° and 212° .—29. *Chloral* added to conc. aqueous solutions of urea forms $(\text{C}_2\text{HClO})_3\text{CON}_2\text{H}_4$ [150°], v. e. sol. hot water, and $(\text{C}_2\text{HClO})_2\text{CON}_2\text{H}_4$ [190°] nearly insol. hot water, both compounds being crystalline (Jacobsen, A. 157, 246). Chloral cyanhydrin at 105° forms the very stable crystalline $\text{C}_2\text{H}_5\text{Cl}_2\text{N}_2\text{O}$ (Pinner a. Fuchs, B. 10, 1069).—30. *Benzene sulphonic chloride* at 100° forms colourless crystals of $\text{C}_6\text{H}_5\text{SONH}_2\text{C}_2\text{O}_2\text{aq}$ (Elander, *Bl.* [2] 54, 207). Naphthalene (a)-sulphonic chloride acts similarly.—31. *Cinnamoyl chloride* forms $\text{C}_6\text{H}_5(\text{NH.CO.NH.C}_6\text{H}_5.\text{NH.CO.NH}_2)_2$ [184°] (Biginelli, B. 24, 2965).—32. ClCH_2OH forms methylene-urea, which is split up by hot dilute H_2SO_4 into formic aldehyde and urea (Von Hemmelmayr, M. 12, 89).—33. *Trichloroacetic acid* and a little water form, on heating, acetylene-urea $\text{C}_2\text{H}_2\text{N}_2\text{O}_2$ (Pinner, B. 17, 1997).—34. *Hexachloro-acetone* (2 mols.) heated with urea (1 mol.) at 150° forms $\text{CO:NH}_2(\text{C}_2\text{Cl}_4\text{O})_2$, crystallising from alcohol in hexagonal plates (Clôéz, A. Ch. [6] 9, 145).

Detection.—Urea gives, in conc. solution, crystalline pps. with nitric and oxalic acids. Urea dissolved in amyl alcohol is completely ppd. by an ethereal solution of oxalic acid (Brücke, M. 8, 195). Musculus (C. R. 78, 182) filters putrid urine, dries the filter at 85° , and employs it as a test for urea, which it converts into ammonium carbonate. A conc. aqueous solution of furfuraldehyde followed by a drop of HCl aq (S.G. 1.10) colours a crystal of urea

violet (Schiff, *B.* 10, 774). *o*-Nitro-benzoic aldehyde added to an alcoholic solution of urea forms, on warming, a white pp. of *o*-nitro-benzylidene-di-urea [200°]. When present in small quantities this compound may be detected by resolving into the parent substances by boiling with very dilute H_2SO_4 , and then adding a little phenylhydrazine solution, which produces a red colour (Lüdy, *M.* 10, 295). Mercuric nitrate gives a white pp. with solutions of urea. The various methods of estimating urea may also be employed for its detection.

Estimation. — Hypobromite method. Urea is mixed with NaOH (100g. in 250 c.c. water) to which bromine (25 g.) has been added, and the nitrogen collected and measured (Knop, *Fr.* 9, 226; Hüfner, *J. pr.* [2] 3, 1; Dupré, *C. J.* 31, 534; Simpson a. O'Keefe, *C. J.* 31, 838; Russell a. West, *C. J.* 27, 749; Eykman, *R. T. C.* 3, 125; Schleich, *J. pr.* [2] 10, 263; Colquhoun, *C. N.* 67, 123; Camerer, *Zeit. Biol.* 29, 239). When this method is applied to urine it must be remembered that uric acid gives off 48 p.c. and creatinin 37 p.c. of its nitrogen in this way (Falk, *Fr.* 21, 300). Nevertheless, the quantity of nitrogen evolved is 8 p.c. less than the calculated amount (R. a. W.). Using Knop's solution, ammonia, urea, and oxamide give off 93, 92.3, and 75 p.c. of their nitrogen as gas (Foster, *C. J.* 33, 470; 35, 119). In the case of urea and oxamide the 'suppressed' nitrogen is present as cyanate and as nitrate (Fauconier; Luther, *H.* 13, 500). The amount of 'suppressed' nitrogen is less in dilute than in concentrated solutions (Hüfner, *H.* 1, 350; cf. Pflüger a. Bohland, *Pf.* 38, 325; 39, 1, 143), and is greatly diminished by the addition of 1 to 5 p.c. acetoacetic ether (Jacoby, *Fr.* 24, 318). According to Duggan (*Am.* 4, 47), if bromine is added to a solution of urea in NaOH aq the yield of nitrogen is 99.4 p.c. of the theoretical amount. In estimating urea in urine Pflüger (*Fr.* 26, 117) adds HCl aq (1 c.c.) to urine (10 c.c.), ppts. various nitrogenous bodies by phosphotungstic acid, neutralises the filtrate with lime and then adds an equal volume of conc. NaOH aq and, after allowing to stand for some time, decomposes with Knop's hypobromite. Frothing of albuminous urine can be avoided by first shaking with a pilule of fat (Méhu, *J. Ph.* [5] 15, 607). Hamburger (*R. T. C.* 2, 181) introduced a volumetric method of employing hypobromite, but Pflüger a. Schenck (*Pf.* 37, 399) consider the method to be untrustworthy. E. Salkowski adds two drops of HCl to urine (2.5 c.c.) diluted with 5 or 10 volumes of water until the air is expelled from the flask, then adds the hypobromite, continues boiling, and collects the nitrogen. Fenton (*C. J.* 33, 300) recommends the use of sodium hypochlorite, which was first proposed by E. W. Davy (A.D. 1854). In this case free NaOH must not be present, though excess of Na_2CO_3 may be present.

Mercuric nitrate method. Urea is completely pptd. by a solution of $\text{Hg}(\text{NO}_3)_2$. The white pp. is not decomposed, and therefore not turned yellow by Na_2CO_3 . Urine (2 vols.) is mixed with a solution (1 vol.) prepared from saturated solutions of baryta (2 vols.) and $\text{Ba}(\text{NO}_3)_2$ (1 vol.); filtered through a dry filter

from the pptd. sulphate and phosphate and 15 c.c. (equivalent to 10 c.c. urine) of the filtrate are titrated with standard mercuric nitrate till a drop taken out gives a yellow pp. with Na_2CO_3 (Liebig, *A.* 85, 370). Assuming the compound $\text{CON}_2\text{H}_2\text{HgO}$ to be formed, 1 pt. urea should ppt. 7.2 pts. HgO , but in practice 7.72 pts. of the latter are required. A solution of 71.48 g. mercury in HNO_3 diluted to 1 litre is equivalent to .01 g. urea per c.c. If the urine contains more than 2 p.c. urea the titration gives too low results; in this case the urine must be diluted. When mercuric nitrate is added to a solution of urea nitric acid is set free. Liebig recommended the addition of Na_2CO_3 from time to time to keep the liquid neutral. Pflüger (*Fr.* 19, 375) proceeds as follows: During the titration, after each addition of $\text{Hg}(\text{NO}_3)_2$, a drop is placed in contact with a little pasty NaHCO_3 . Long before the titration is ended, a yellow colour is seen between the two drops, but disappears on mixing them together. When the yellow colour is permanent, the titration is near its end; at this point the solution is neutralised by Na_2CO_3 , and the titration continued till a permanent yellow colour is got on mixing the drops. Should the entire liquid become yellow on adding Na_2CO_3 , a fresh quantity of urea solution must be taken and the operation be repeated with greater speed. The presence of over 1 p.c. NaCl in urine interferes with the titration when Na_2CO_3 is used as indicator, the final reaction not being sharp. Since NaHCO_3 does not ppt. HgCl_2 , when the bicarbonate is used as indicator the titration may proceed as if NaCl were absent, subtracting the amount of $\text{Hg}(\text{NO}_3)_2$ that is converted into HgCl_2 by the chloride (Rautenburg, *A.* 133, 55; Pfeiffer, *Fr.* 24, 475; Pflüger, *Fr.* 27, 120). It is, however, better to ppt. the chlorides by AgNO_3 and titrate in the usual way.

Barium carbonate method. The solution is heated with BaCl_2 and NH_4Aq in sealed tubes at 220°–240° and the pptd. BaCO_3 weighed (Bunsen, *A.* 65, 875). Before applying this method to urine other substances which might form BaCO_3 must be pptd. by phosphotungstic acid (Pflüger a. Bleibtreu, *Fr.* 28, 377).

Kjeldahl's method. Nitrogen in urea may be estimated by Kjeldahl's method. 5 c.c. urine are heated with H_2SO_4 (10 c.c.), and Nordhausen H_2SO_4 (10 c.c.) until no more water or gas comes off, and the liquid is clear yellow. After cooling, water (200 c.c.) and NaOH are added and NH_3 distilled off. In the case of urine it must be remembered that about 13 p.c. of the nitrogen is, on an average, combined in substances other than urea (Pflüger, *Pf.* 35, 454; 40, 533; Camerer, *Z. B.* 24, 306).

Other methods. Urea may also be estimated by fermentation and determination of ammonia set free (Miquel, *C. R.* 111, 501).

Campani (*G.* 17, 187) proposes to decompose urea by nitrous acid and pass the CO_2 into a solution of lime-water of known strength, and titrate with oxalic acid.

Cazeneuve and Hugouneng (*Bl.* [2] 48, 82) heat urea with a large excess of water and titrate the resulting ammonium carbonate.

Riegler (*Fr.* 33, 49) decomposes urea with Millon's reagent and measures the mixture of N and CO_2 evolved.

Möner a. Sjöqvist (*Fr.* 80, 388) add 5 c.c. of a saturated solution of BaCl_2 containing 5 p.c. baryta to 5 c.c. urine and then add 100 c.c. of a mixture of 97 p.c. alcohol (2 pts.) and ether (1 pt.). After 24 hours the liquid is filtered, the pp. washed with 50 c.c. alcohol-ether, and the filtrate and washings evaporated at 50° to 25 c.c., MgO and some water added, and the evaporation continued as long as NH_3 comes off. The urea is then determined by Bunsen or Kjeldahl's method (Böttker, *H.* 17, 140).

Salts.— B'HCl . Very deliquescent crystalline mass, formed from urea and dry HCl . Decomposed by water into urea and HCl . At 140° it yields NH_4Cl and cyanuric acid.— B'HNO_3 . Small plates, sl. sol. water and alcohol, v. sl. sol. HNO_3 .— $\text{B}_2\text{H}_2\text{C}_2\text{O}_4$. S. 4.4 at 15° . S. (alcohol of S.G. .833) 1.65. Monoclinic tables; $a:b:c = 1:564:491$; $\alpha = 82^\circ 10'$ (Loschmidt, *Sitz.* W. 51, ii. 7, 384). V. sol. hot water. Ppd. from its aqueous solution by oxalic acid.— $\text{B'H}_2\text{C}_2\text{O}_4\text{aq}$ (Lubavin, *A. Suppl.* 8, 83).— $\text{B'HAuCl}_4\text{aq}$: orange-red prisms or needles, v. sol. water, alcohol, and ether.— B'HAuCl_4 : yellow needles, v. sol. hot water (Heintz, *A.* 202, 264).— $\text{B}_2\text{H}_2\text{PtCl}_2\text{aq}$. Yellow, deliquescent tables, v. sol. water and alcohol, insol. ether (Heintz, *A.* 198, 91).— $\text{B'H}_3\text{PO}_4$. Large crystals, v. sol. water and alcohol, sl. sol. ether (Lehmann, *Buchn. Rep.* 15, 224; Schmeltzer a. Birnbaum, *Z.* [2] 5, 206). Its solution does not ppt. MgSO_4 .— $\text{B}_2\text{H}_2\text{PO}_4$. Its aqueous solution gives a crystalline pp. of cyanuric acid on heating.

Tri-chloro-acetate $\text{B'C}_2\text{HClO}_4$. Plates (from alcohol) (De Clermont, *J.* 1873, 536).—The fumarate $\text{B}_2\text{C}_2\text{H}_2\text{O}_4$, maleates $\text{B}_2\text{C}_2\text{H}_2\text{O}_4$, and $\text{B}_2\text{C}_2\text{H}_2\text{O}_4$, malate $\text{B}_2\text{C}_2\text{H}_2\text{O}_4$, gallate $\text{B}_2\text{C}_2\text{H}_2\text{O}_4$, and succinate $\text{B}_2\text{C}_2\text{H}_2\text{O}_4$ [145°], all crystallise in monoclinic forms (Loschmidt, *Sitz.* W. 52, ii. 238). The parabanate $\text{B}_2\text{C}_2\text{H}_2\text{N}_2\text{O}_4$ and tartrate $\text{B}_2\text{C}_2\text{H}_2\text{O}_4$ are trimetric.—The citrate $\text{B}_2\text{C}_2\text{H}_2\text{O}_4$ is triclinic (L.). An acid tartrate $\text{B}_2\text{C}_2\text{H}_2\text{O}_4$ and an acid citrate $\text{B}_2\text{C}_2\text{H}_2\text{O}_4$ have been prepared (Hlasiwetz, *J.* 1856, 698).—Cyanurate $\text{B}_2\text{C}_2\text{H}_2\text{O}_4$. Monoclinic crystals.—Picrate $\text{B}_2\text{C}_2\text{H}_2\text{N}_2\text{O}_4$ [142°] (Smolka, *M.* 6, 920). S. 1.9 at 18.5° . S. (95 p.c. alcohol) 6 at 18° . Slender yellow needles (from alcohol). Tri-chloro methane sulphinate $\text{B'CCl}_2\text{SO}_2\text{H}$. [96°–100°]. Thin prisms (McGowan, *J. pr.* [2] 36, 220).

Compounds with metallic oxides.— $\text{B}_2\text{Ag}_2\text{O}$ (Liebig). Formed by adding moist Ag_2O to a solution of urea. Grey powder composed of slender needles. According to Müller (*B.* 6, 1019), the yellow pp. got by adding NaOH to a solution of urea mixed with AgNO_3 is $\text{CON}_2\text{H}_4\text{Ag}$. It combines with iodine, forming $\text{CON}_2\text{H}_4\text{AgI}$, a greenish mass, darkened by light (Tafel a. Enoch, *B.* 23, 1554).— B'HgO . Got by adding $\text{Hg}(\text{NO}_3)_2$ to a solution of urea mixed with KOH . White pp.— B_2HgO . White pp. formed by adding HgCl_2 to a solution of urea and HgCl_2 changes to a yellow granular powder on boiling with water.— B_2HgO . Formed by adding $\text{Hg}(\text{NO}_3)_2$ to a warm solution of urea (Dessaignes, *A.* 82, 232; Liebig, *A.* 85, 289).

Compounds with metallic salts.— B'AgNO_3 . Prisms. Yields silver cyanate on

boiling with water.— B'PdCl_2 . Ppd. by adding a solution of PdCl_2 to one of urea (Drechsel, *J. pr.* [2] 20, 469).— B'NaClaq . [60°–70°]. Formed by evaporation of a solution of urea and NaCl . Deliquescent prisms. Alcohol extracts urea from the compound.— $\text{B'NaNO}_3\text{aq}$. Prisms (from water).— $\text{B'NH}_4\text{Cl}$. Deliquescent crystals.— $\text{B}_2(\text{NH}_4\text{Cl})_2\text{HCl}$. Formed by dissolving urea in bleaching-powder solution (Beckmann, *A.* 91, 367). Large plates, sol. alcohol mixed with ether.— $\text{B'Mg}(\text{NO}_3)_2$ (Werther, *J. pr.* 85, 5).— $\text{B'_Ca}(\text{NO}_3)_2$.— B'_ZnCl_2 . Very deliquescent crystals (Neubauer a. Kerner, *A.* 101, 337).— B'CdCl_2 . Needles.— $\text{B'_Hg}(\text{NO}_3)_2\cdot 3\text{HgO}$. Granular powder formed by mixing warm dilute solutions of urea and mercuric nitrate. At the moment of formation the pp. is flocculent.— $\text{B'_Hg}(\text{NO}_3)_2\cdot 2\text{HgO}$. Formed by pouring mercuric nitrate into a solution of urea as long as a pp. is produced, and keeping the whole at 40° to 50° for some time (Liebig). Six-sided laminae.— $\text{B'_Hg}(\text{NO}_3)_2\cdot \text{HgO}$. Formed by adding an acid solution of mercuric nitrate to a solution of urea nitrate. Crusts of small tabular crystals (Liebig, *A.* 85, 296).— B'HgCl_2 . Flat crystals, v. sl. sol. cold water (W.).— $\text{B}_{12}\text{Cr}_2\text{O}_{21}\cdot 3\text{aq}$. Formed by the action of water on the product of the action of CrO_2Cl_2 on urea (W. J. Sell, *Pr.* 33, 267; 45, 321). Olive-green needles (from hot water). PtCl_4 added to its solution in hot water ppts. silky green needles of $\text{B'_Cr}_2\text{Cl}_2(\text{PtCl}_4)_2\text{aq}$. The chromate treated with PbCl_2 forms lead chromate and a liquid from which gaseous HCl ppts. green prisms of $\text{B'_Cr}_2\text{O}_6\cdot 6\text{aq}$, the aqueous solution of which heated with Ag_2SO_4 gives dark-green prisms of $\text{B'Cr}_2(\text{SO}_4)_3\cdot 10\text{aq}$. In a similar way green prisms of $\text{B'Cr}_2(\text{NO}_3)_4$ may be got.— $\text{B'_Cr}_2\text{Cl}_2\text{O}_4\cdot 2\text{aq}$. Green monoclinic crystals, got from the product of the action of CrO_2Cl_2 on urea by crystallising from conc. HClaq (1 vol.) diluted with water (9 vols.). By treatment with water it is split up into $\text{B'Cr}_2\text{O}_{21}$ and $\text{B'_Cr}_2\text{Cl}_2$. By treatment with conc. HClaq (1 vol.) and water (6 vols.) it is converted into the salts $\text{B'_Cr}_2\text{Cl}_2\text{O}_{12}\cdot 3\text{aq}$.— $\text{B'_Cr}_2\text{O}_{14}\cdot 4\text{aq}$.— $\text{B'_Cr}_2\text{Br}_2\cdot 6\text{aq}$.— $\text{B'_Cr}_2\text{Cl}_2\cdot 6\text{HgCl}_2$.— $\text{B'_Cr}_2(\text{CO}_3)_2\cdot 4\text{aq}$.— $\text{B'_Cr}_2\text{I}_2$.— $\text{B'_Cr}_2(\text{SO}_4)_2\cdot \text{I}_2$.— $\text{B'_Cr}_2(\text{CO}_3)_2\cdot \text{I}_2$.— $\text{B'_Cr}_2(\text{CO}_3)_2\cdot \text{I}_2$.— $\text{B'_Cr}_2\text{Br}_{11}$. Bronze-yellow tables, giving off bromine in air.— B'_CuCl_2 . Small blue crystals.

Formyl derivative $\text{NH}_2\text{CO.NH.CHO}$. [159°]. H.F. 13,400 (Matignon, *C. R.* 112, 1867). Formed by boiling urea with conc. formic acid (Geuther, *Z.* [2] 4, 300). Crystals, v. sol. water, being decomposed into urea and formic acid.

Acetyl derivative $\text{C}_2\text{H}_5\text{N}_2\text{O}_2$, i.e. $\text{NH}_2\text{CO.NHAc}$. *Acetureide*. Mol. w. 102. [214°]. H.F. –200 (M.). S. (alcohol) 1 in the cold; 10 at 78° . Formed by boiling urea with AcCl or Ac_2O (Zinin, *A.* 92, 405; G.; Zander, *R. T. C.* 8, 235). Got also by the action of KMnO_4 on methyl-uracil (Behrend, *A.* 229, 29). Four-sided needles (from alcohol). Slowly but completely decomposed by pure HNO_3 with evolution of CO_2 (1 vol.) and N_2O (2 vols.) (Franchimont, *R. T. C.* 6, 215). It is not ppd. by $\text{Hg}(\text{NO}_3)_2$.

Di-acetyl derivative $\text{CO}(\text{NHAc})_2$. [153°]. A product of the action of COCl_2 on acetamide at 50° (Schmidt, *J. pr.* [2] 5, 68).

Formed also from mercurio fulminate and AcCl (Scholl, *B.* 23, 3515). Needles (from alcohol), sl. sol. cold water.

Chloro-acetyl derivative

$\text{NH}_2\text{CO.NH.CO.CH}_2\text{Cl}$. Formed from chloro-acetyl chloride and urea (Jazukovitch, *Z.* 1868, 234; Tommasi, *C. R.* 76, 640). Thin needles (from alcohol). Begins to melt at 160° .

Tri-chloro-acetyl derivative

$\text{NH}_2\text{CO.NH.CO.CCl}_3$. [150°]. Crystals (from alcohol) (De Clermont, *J.* 1874, 798; Meldola & Tommasi, *C. J.* 1874, 404; Cloez, *A. Ch.* [6] 9, 219). Nearly insol. hot water.

Bromo-acetyl derivative

$\text{NH}_2\text{CO.NH.CO.CH}_2\text{Br}$. Needles (from dilute alcohol) (Baeyer, *A.* 130, 156). Pure HNO_3 gives off CO_2 (1 vol.) and N_2O (2 vols.) (Franchimont, *P. T. C.* 6, 218).

Tri-bromo-acetyl derivative

$\text{NH}_2\text{CO.NH.CO.CBr}_3$. [148°]. Formed by the action of Br on an aqueous solution of di-bromo-barbituric acid (Baeyer). Crystals, v. sol. hot alcohol. Yields crystalline $\text{B}^2\text{Ba}(\text{OH})_2$ aq, v. e. sol. water.

Cyano-acetyl derivative

$\text{NH}_2\text{CO.NH.CO.CH}_2\text{Cy}$. [200°–210°] (Mulder, *B.* 12, 466). Crystalline.

Butyryl derivative $\text{NH}_2\text{CO.NHC}_3\text{H}_7\text{O}$

[176°]. Formed from urea and butyryl chloride (Moldenhauer, *A.* 94, 101). Plates.

Isovaleryl derivative $\text{C}_4\text{H}_9\text{N}_2\text{O}_2$

[191°]. Minute prisms, v. sl. sol. water.

Carbonyl derivative $\text{CO}(\text{NH.CO.NH})_2$

Formed by heating urea with COCl_2 at 100° (E. Schmidt, *J. pr.* [2] 5, 39; Emich, *M.* 10, 347). Powder composed of minute crystals, v. sl. sol. cold water and alcohol. Decomposed by heat into NH_3 and cyanuric acid. Boiling KOH also produces cyanuric acid.— B^2HgO : crystalline powder, insol. water.

Succinyl derivative

$\text{C}_4\text{H}_5\text{O}_2(\text{NH.CO.NH})_2$. Formed by heating urea (2 mols.) with succinyl chloride (1 mol.) at 65° (Conrad, *J. pr.* [2] 9, 301). Colourless powder, v. sl. sol. hot water.

Methyl-malonyl derivative

$\text{CHMe:C}_2\text{O}_2\text{N}_2\text{H}_2\text{CO}$. [192°]. Formed by heating methyl-malonic acid with urea and POCl_3 (Franchimont & Klobbie, *R. T. C.* 7, 22). Pointed plates, v. sol. water and alcohol.

Benzoyl derivative $\text{NH}_2\text{CO.NHBz}$

[c. 200°]. S. (alcohol) 1 in the cold; 4 at 78° . Formed by heating urea with BzCl or Bz_2O at 150° (Zinin, *A.* 92, 404; Geuther, *Z.* [2] 4, 299). Four-sided plates (from alcohol), insol. ether).

Di-benzoyl derivative $\text{CO}(\text{NHBz})_2$

[210°] (S.); [197°] (H.). A product of the action of COCl_2 on benzamide at 165° (E. Schmidt, *J. pr.* [2] 5, 58). Formed also by heating guanidine carbonate with Bz_2O at 100° (Creath, *B.* 7, 1789), and by treating mercurio fulminate with BzCl (Holleman, *R. T. C.* 10, 72; *B.* 23, 2998, 8742). Needles (from alcohol), sl. sol. water. Aniline at 180° gives NH_3 , benzamide, benzanilide, and *s*-di-phenyl-urea.

u-Di-benzoyl derivative $\text{NH}_2\text{CO.NBz}_2$

[c. 197°]. Formed by heating sodium benzoyl-cyanamide NaBzN.ON with BzCl , followed by boiling alcohol (Buddéus, *J. pr.* [3] 42, 97). White needles.

VOL. IV.

m-Nitro-benzoyl derivative

$\text{NH}_2\text{CO.NH.CO.C}_6\text{H}_4\text{NO}_2$ [1:8]. Plates (Griess, *B.* 8, 222).

m-Amido-benzoyl derivative $\text{C}_6\text{H}_4\text{N}_2\text{O}_2$

Formed by boiling the preceding body with aqueous ammonium sulphide (G.). Needles (from water), decomposing at 200° . — B^2HCl aq: needles.— $\text{B}^2\text{H}_2\text{PtCl}_6$.

(\beta)-Naphthoyl derivative

$\text{NH}_2\text{CO.NH.CO.C}_{10}\text{H}_7$. [215°]. Formed from naphthoyl chloride and urea (Vieth, *A.* 180, 319). Minute needles, m. sol. alcohol, v. sl. sol. benzene.

Di-(\beta)-naphthoyl urea [286°] (Ekstrand, *B.* 20, 1853). Needles.

Lactyl derivative v. LACTYL-UREA.

Glycollyl derivative v. HYDANTOIN.

Reference.—OXY-UREA.

UREA CARBOXYLIC ACID v. ALLOPHANTIC ACID.

UREA CHLORIDES. A name sometimes used to denote alkyl-carbamic chlorides X.NH.CO.Cl .

URECHITIN $\text{C}_{28}\text{H}_{42}\text{O}_8$. Occurs, together with urechitoxin, in the leaves of *Urechites suberecta*, growing in Jamaica (Bowrey, *C. J.* 33, 252). Crystallises from alcohol in needles (containing aq), tastes bitter. It is very poisonous (*Pr.* 27, 309). Nearly insol. water, m. sol. ether. Appears to be a glucoside. Conc. H_2SO_4 forms a yellow liquid, turning red, and finally purple, especially in presence of an oxidising agent.

Urechitoxin $\text{C}_{18}\text{H}_{20}\text{O}_8$. Bitter poison, split up by acids into sugar and urechitoxetin.

UREIDES. Compounds obtained by elimination of water between urea and an acid or an aldehyde. Many of them may be represented as amides in which NH_2 is replaced by NH.CO.NH_2 .

BIURET v. vol. i. p. 517.

URETHANE v. CARBAMIC ETHER.

ISURETINE v. FORMAMIDOXIM.

URIC ACID $\text{C}_5\text{H}_4\text{N}_2\text{O}_6$, i.e.

$\text{CO} \begin{array}{c} \text{NH.CO.C.NH} \\ \text{NH} \end{array} \text{CO} \begin{array}{c} \text{NH.CO.C.NH} \\ \text{NH} \end{array} \text{CO}$ (Medicus, *A.* 175, 243; Fischer, *B.* 17, 329, 1776). Mol. w. 168. S.G. 1.87. H.C.p. 461,400 (Berthelot, *C. R.* 110, 887; Matignon, *C. R.* 110, 1267); 462,500 (Stohmann, *J. pr.* [2] 44, 390). H.C.v. 462,700 (M.). H.F. 148,100 (M.). S. .002 at 0° ; .006 at 20° ; .0625 at 100° (Blarez & Denigès, *C. R.* 104, 1847; cf. Garrod, *Pr.* 35, 63).

Occurrence.—In urine and in urinary calculi (Scheele, *A.D.* 1776; Liebig & Wöhler, *A.* 26, 241; Horbaczewski, *M.* 12, 221). About .5 g. is daily excreted in human urine. Uric acid occurs in urine of carnivora, herbivora (Mittelbach, *H.* 12, 468), and of birds. Serpent's urine is chiefly composed of acid ammonium urate. A considerable quantity occurs in the blood of gouty subjects, and sodium urate is deposited as 'chalk stones.' Very small quantities are normally present in the liver, lungs, brain, and blood. It occurs in the green gland of the fresh-water crayfish (Griffiths, *Pr.* 88, 187). Urea, glycocholl, leucine, and aspartic acid given to fowls appear in the urine as uric acid (Jaffé & Meyer, *B.* 10, 1930; Knierim, *B.* 10, 1930).

Synthesis.—1. By rapidly heating glycocholl (1 pt.) with urea (10 pts.) to 230° (Horbaczewski, *B.* 15, 2678; *M.* 8, 796; 6, 856).—2. By heating

8 H

urea with tri-chloro-lactic acid or its amide (Horbaczewski, *M.* 8, 201, 584).—3. By preparing methyl-uracil from acetoacetic ether and urea; converting methyl-uracil into nitro-uracil carb-oxylic acid by treatment with fuming HNO_3 ; boiling the carboxylic acid with water, and reducing the resulting nitro-uracil to amido-uracil, and finally to isobarbituric acid by means of tin and HClAq ; oxidising the isobarbituric acid to isodialuric acid; and heating the isodialuric acid (1 pt.) with urea (1 pt.) and H_2SO_4 (6 pts.) (Behrend & Roosen, *A.* 251, 235).—4. By fusing urea (4 g.) with cyano-acetic acid (1 g.) (Formánek, *B.* 24, 8419).

Preparation.—1. Serpent's urine is dissolved in boiling KOHAc , filtered, and the uric acid ppd. by HCl or dilute H_2SO_4 . If the uric acid is much coloured a little KMnO_4 or $\text{K}_2\text{Cr}_2\text{O}_7$ (Gibbs, *Am. S.* [2] 48, 215) should be added to the boiling alkaline solution before ppn.—2. Guano is boiled with borax (1 pt.) and water (120 pts.), and the solution of sodium urate thus obtained ppd. by HCl .—3. Guano is extracted with dilute HClAq , and the residue dissolved in conc. H_2SO_4 and ppd. by water.

Properties.—White anhydrous scales (by ppn.). When slowly deposited from dilute solutions (e.g. urine) it separates as large crystals (containing 2aq). Nearly insol. water, insol. alcohol and ether. Sol. conc. H_2SO_4 and reppd. by water. Its solution in hot H_2SO_4 deposits on cooling a deliquescent compound of uric acid with H_2SO_4 . Uric acid is m. sol. glycerin, hot NaOAc , and sodium phosphate. Lithium carbonate (1 pt.) dissolved in water (90 pts.) can dissolve uric acid (4 pts.). Aqueous K_2CO_3 also dissolves uric acid.

Reactions.—1. Decomposed by heat, without fusion, yielding HCy and a sublimate of cyanuric acid, ammonium cyanate, urea, and ammonium carbonate, and leaving a carbonaceous residue. 2. Water at 180° forms mycemic acid (Hlasiwetz, *A.* 103, 211).—3. Potash-fusion yields NH_3 and potassium oxalate, carbonate, and cyanate.—4. Chlorine and bromine in presence of water yield alloxan, urea, and parabanic acid (Hardy, *A. Ch.* [4] 2, 372). Alloxan is also produced by iodine, by HNO_3 , and by MnO_2 and H_2SO_4 .—5. Boiling with water and PbO_2 yields allantoin. Allantoin is also produced by osone (Gorup-Besanez, *A.* 110, 94), alkaline K_2FeCy_6 , KMnO_4 (Claus, *B.* 7, 226), and MnO_2 and water. 6. Pure HNO_3 decomposes uric acid in the cold, with evolution of CO_2 (14 vols.), N_2O (24 vols.), and nitrogen (4 vols.) (Franchimont, *R. T. O.* 6, 222). 7. KNO_3 and HOAc yield urinic acid (Sokoloff, *Z.* [2] 5, 78) and styphnic acid (Gibbs, *Am. S.* [2] 48, 215).—8. HIAq at 165° forms glycooall, NH_4I , and CO_2 (Strecker, *Z.* [2] 4, 215).—9. Exposed to the air in alkaline solution it yields oxonic and uroxanic acids.—10. A dilute solution of sodic urate absorbs oxygen from the air at 35° according to the equation $\text{C}_4\text{H}_3\text{N}_3\text{O}_6 + \text{O} + 2\text{H}_2\text{O} = \text{C}_4\text{H}_3\text{N}_3\text{O}_8$ (uroxanic acid). Uric acid in dilute NaOH solution is completely decomposed by 85 days' digestion at 35° (Nencki & Sieber, *J. pr.* [2] 26, 18). 5 g. uric acid dissolved in 200 c.c. water and 20 g. potash disappeared in 5 days. However, if no oxygen be present the uric acid is not affected.—11. In fermenting urine uric

acid is completely split up into CO_2 and NH_3 (Sestini, *G.* 20, 133).

Detection.—Uric acid may be recognised by its insolubility in water and HClAq , by its crystalline character under the microscope, and especially by the murexid- reaction. When evaporated with HNO_3 on a water-bath it leaves an orange residue, which is coloured violet-red by ammonia and violet-blue by potash. A solution of uric acid in aqueous Na_2CO_3 produces a dark-brown spot of reduced silver when added to paper moistened with AgNO_3 (Schiff, *A.* 109, 65). Uric acid (1 mol.) reduces boiling Fehling's solution, forming a pp. of Cu_2O (1 mol.) (W. Müller, *J. Th.* 1881, 78). In presence of KOH uric acid dissolves CuO , forming a blue solution, which slowly deposits white cuprous urate. The compound $\text{C}_4\text{H}_3\text{N}_3\text{O}_6\text{Cu}_2\text{O}$ is ppd. when an alkaline solution of uric acid is treated with Fehling's solution and hydroxylamine hydrochloride (Balke, *J. pr.* [2] 47, 546). Uric acid evaporated with a little dilute HNO_3 gives a blue colour on shaking with H_2SO_4 and benzene containing thiophene (Denigès, *J. Ph.* [5] 18, 161).

Estimation in urine.—1. Urine (500 c.c.) is concentrated, HCl is added, and after twenty-four hours the pp. is collected and weighed. Uric acid may be separated from xanthine by ppn. with conc. H_2SO_4 (Horbaczewski, *H.* 18, 341; cf. Wulff, *H.* 17, 634).—2. Urine (200 c.c.) is mixed with conc. $\text{Na}_2\text{CO}_3\text{Aq}$ (10 c.c.), and after an hour conc. NH_4ClAq (20 c.c.) added. After forty-eight hours the pp. is collected, washed with HCl (1 pt. of S.G. 1.123), diluted with water (10 pts.), the washings allowed six hours to deposit any dissolved uric acid, the combined pps. washed with alcohol and dried at 110° (Salkowski, *Fr.* 16, 373). Uric acid may also be ppd. as ammonium urate by saturating urine with solid NH_4Cl (30 g. to 100 c.c.) (Hopkins, *Pr.* 52, 93).—3. Fresh urine is mixed with very dilute (15 p.c.) NaOHAc , filtered from phosphates, and diluted to S.G. 1.010. To 300 c.c. of this solution is added 50 c.c. of magnesia mixture [MgSO_4 , 7aq (1 pt.), NH_4Cl (2 pts.), NH_4Aq (4 pts. of S.G. .924), and water (8 pts.)]. The pp. is filtered off, and 175 c.c. of the filtrate mixed with 5 g. CaCO_3 and 5 c.c. of a 8 p.c. solution of AgNO_3 . The pp. is washed and dried, and a nitrogen estimation made by Kjeldahl's method (Camerer, *Z. B.* 28, 84; cf. Salkowski, *Pf.* 5, 819).—4. Urine (25 c.c.) is mixed with NaHCO_3 (1 g.) and NH_4Aq (2 to 3 c.c.), and ammoniacal AgNO_3 (1 to 2 c.c. of a solution of 5 g. AgNO_3 in 100 c.c. water, to which NH_4Aq is added till the ppd. Ag_2O is just re-dissolved). The pp. is collected, washed, dissolved in HNO_3 , and the silver determined volumetrically by the sulphocyanide method (Haycraft, *Fr.* 25, 167; 30, 648). This method is liable, according to Salkowski (*H.* 14, 31) and Gossage (*Pr.* 44, 284), to an error which may amount to 60 p.c. The error is partly due to variations in composition of the silver urate, and partly to presence of bodies of the xanthine group (Deroide, *Bl.* [8] 7, 863). V. also Herrmann, *H.* 12, 496; Czapek, *H.* 12, 502).—5. In a solution containing not more than .0125 p.c. of uric acid 1 c.c. of decimormal permanganate is reduced by .0074 g. uric acid (Blazac & Denigès, *C. R.* 104, 789).—6. By treat-

ment with a standard iodine solution in presence of alkali (Kreidl, *M.* 14, 109).

Salts.— $(\text{NH}_4)\text{HA}''$. S. '06 at 15°. Slender needles.— $(\text{NH}_4)_2\text{HA}''_2$ — $(\text{NH}_4)_2\text{H}_2\text{A}''$ (Maly, *J.* 1863, 621).— $\text{K}_2\text{A}''$. S. 3 at 16°. Small needles.— KHA'' . S. '13 at 20°. Amorphous.— $\text{Na}_2\text{A}''$ aq. S. 1-5. Nodules.— NaHA'' $\frac{1}{2}$ aq (dried at 100°). Crystalline powder. S. '09 at 15°; '8 at 100°. Occurs as an amorphous urinary deposit.— LiHA'' . S. '27 at 20°; '9 at 40°; 2-5 at 100° (Schilling, *A.* 122, 241).— BaA'' aq (dried at 100°). Granular pp. S. '013 in the cold.— $\text{BaH}_2\text{A}''_2$ 2aq (dried at 100°). Amorphous, insoluble powder (Behrend a. Roosen, *A.* 251, 250).— CaA'' . S. '066 in the cold; '7 at 100°.— $\text{CaH}_2\text{A}''_2$ 2aq. S. '15 in the cold; '37 at 100°. More sol. KClAq .— SrA'' 2aq. Minute stellate groups of needles. S. '023 in the cold; '055 at 100°.— $\text{SrH}_2\text{A}''_2$ 2aq.— $\text{MgH}_2\text{A}''_2$ 6aq. S. '03 in the cold; '6 at 100°.— $\text{PbH}_2\text{A}''_2$ 'dried at 100°. Insol. water.— PbA'' (dried at 100°).— $\text{Cu}_2\text{A}''$ aq.— $\text{Cu}_2\text{A}''_2(\text{OH})_2$ 4aq: green pp.

Reference.—METHYL-URIC ACID.

Iso-uric acid $\text{C}_5\text{H}_7\text{N}_3\text{O}_6$. Formed by boiling cyanamide (1 pt.) with an aqueous solution of alloxantin (2 pts.) (Mulder, *B.* 6, 1236; 7, 1633). Powder, almost insol. water. Oxidised by boiling with I and water. Its solution in K_2CO_3 reduces AgNO_3 .

Pseudo-uric acid $\text{C}_5\text{H}_7\text{N}_3\text{O}_6$, i.e.

$\text{CO} \begin{smallmatrix} \text{NH.CO} \\ \text{NH.CO} \end{smallmatrix} \text{CH.NH.CO.NH}_2$. Formed by the action of KCyO on uramil (Baeyer, *A.* 127, 3), and by heating uramil with urea at 180° (Grimaux, *Bl.* [2] 31, 535). White crystalline powder composed of small prisms, v. sl. sol. water. HNO_3 yields alloxan. Boiled with water and PbO , it yields oxalic acid, but no allantoin. H_2SO_4 at 150° forms xanthinine.— $(\text{NH}_4)\text{HA}''$ aq.— KHA'' aq.: scales.— NaHA'' 2aq: groups of prisms, v. sol. hot water.— BaA'' 5aq: groups of slender needles.

URINILIC ACID $\text{C}_8\text{H}_9\text{N}_3\text{O}_6$. Formed by the action of KNO_3 and HOAc on uric acid (Sokoloff, *Z.* 1869, 78). Prisms (from water).— $\text{K}_2\text{HA}'''$. Prisms, v. e. sol. water. $\text{Ca}_2\text{A}'''_2$. Crystalline pp. insol. water and HOAc .— SrA'''_2 .— BaA'''_2 .— CdHA''' 8aq.— CuHA''' 4aq. Slender red needles.— $\text{Ag}_2\text{HA}'''$. Pp.— $\text{Ag}_2\text{A}'''$. Gelatinous pp. quickly blackening in light.

UROBILIN.

Occurrence.—Often in urine (Jaffé; Disqué, *H.* 2, 271; *C. C.* 1878, 711; Eikholz, *J. Physiol.* 14, 326). In bile, especially of the mouse.

Preparation.—Urine containing urobilin is ppd. by lead acetate and sub-acetate until the absorption band at F is removed. The pp. is extracted with alcohol, acidified with HCl or H_2SO_4 , filtered, diluted with water, and extracted with chloroform.

Properties.—A red amorphous, shiny substance. Prepared as above it contains HCl or H_2SO_4 , as the case may be. Its spectrum exhibits a dark band at F, destroyed by NH_3 , but on adding NaOH another band near the red is formed (MacMunn, *Pr.* 30, 250; 31, 26, 206; v. also *HYDROBILIRUBIN*, this vol. p. 273).

Detection and estimation in urine: Jolles, *H.* 18, 545; Studansky, *C. C.* 1893, ii. 668.

UROCANINIC ACID $\text{C}_{12}\text{H}_9\text{N}_3\text{O}_6$. [218°]. Occurs in dog's urine (Jaffé, *B.* 7, 1669; 8, 811).

Prisms (containing 4aq), v. sol. hot water, insol. alcohol and ether. Decomposed by fusion into CO_2 and urocanine $\text{C}_{11}\text{H}_9\text{N}_3\text{O}$, an amorphous base yielding $\text{B'H}_2\text{PtCl}_4$.— $\text{HA}'2\text{HCl}$: needles, v. e. sol. water.— $\text{HA}'2\text{HNO}_3$: crystalline pp. insol. dilute HNO_3 , v. sol. water.— $\text{HA}'\text{H}_2\text{SO}_4$. Minute needles and plates.

UROCHLORALIC ACID $\text{C}_8\text{H}_7\text{Cl}_3\text{O}$ (?) [142°]. S. (ether) 4. Found in the urine after administration of chloral (Von Mering a. Musculus, *B.* 8, 662; *H.* 6, 483; Külz, *C. C.* 1881, 486). Silky needles, v. e. sol. water and alcohol. Decomposed by boiling dilute H_2SO_4 into tri-chloroethyl alcohol and glycuronic acid $\text{C}_6\text{H}_9\text{O}_6$.— NaA' .— KA' .— BaA'_2 : satiny plates (from ether-alcohol).

UROFUSCOHEMATIN v. this vol. p. 274.

UROLEUCIC ACID $\text{C}_6\text{H}_9\text{O}_6$. [133-5°]. An acid occurring in human urine which darkens on addition of alkalis (Kirk, *Brit. Med. Journ.* [1888] 2, 232). Crystals. Its solution is ppd. by $\text{Pb}(\text{OAc})_2$ and gives a transient green colour with very dilute FeCl_3 . FeCl_3 colours the crystals red.

UROMELANIN $\text{C}_{11}\text{H}_{13}\text{N}_3\text{O}_{10}$. A black substance which separates on treating urine with H_2SO_4 or HClAq in presence in air (Thudichum, *J. pr.* 104, 257; *C. R.* 106, 1803; Plossz, *H.* 8, 89; Udranski, *H.* 11, 537; 12, 32; this vol. p. 274). It yields $\text{C}_{11}\text{H}_{10}\text{AgN}_3\text{O}_9$ (Thudichum).

URONITROTOLUOLIC ACID $\text{C}_{11}\text{H}_9\text{N}_3\text{NO}_6$. Occurs in urine of dogs after a dose of *o*-nitrotoluene (Jaffé, *H.* 2, 47). Very deliquescent. Asbestos-like mass, v. e. sol. water and alcohol. Decomposed by dilute H_2SO_4 into *o*-nitro-benzyl alcohol and a syrupy acid. Salts.— BaA'_2 : crystalline powder, v. e. sol. water, insol. alcohol.— $\text{CO}(\text{NH}_2)_2\text{HA}'_2$ $\frac{1}{2}$ aq. [149°]. Needles, v. e. sol. water, sl. sol. cold alcohol.

UROROSEIN v. this vol. p. 274.

UROSULPHINIC ACID $\text{C}_8\text{H}_9\text{N}_3\text{SO}_6$. Formed by heating thio-uramido-barbituric acid (1 pt.) with H_2SO_4 (2 pts.) at 160° (Nencki, *B.* 4, 724; 5, 45). Nodules (from hot HClAq). Its K salt crystallises in needles, m. sol. cold water.

UROXANIC ACID $\text{C}_8\text{H}_9\text{N}_3\text{O}_6$. Formed by leaving a solution of uric acid (5 g.) in water (200 c.c.) containing KOH (20 g.) to stand for 5 days at 85°, neutralising by HOAc , filtering, and evaporating (Nencki a. Sieber, *J. pr.* [3] 24, 504; cf. Städeler, *A.* 78, 286; 80, 119; Strecker, *A.* 155, 177; Mulder, *B.* 8, 1291). Tetrahedra, sl. sol. cold water, insol. alcohol. Decomposed by boiling water into CO_2 , urea, and allanturic acid.— $\text{K}_2\text{A}''$ 8aq. Four-sided pearly plates, v. sol. hot water.— CaA'' 4aq.— BaA'' 5aq.— PbA'' $\frac{1}{2}$ aq. Insol. water.— $\text{Ag}_2\text{A}''$: flocculent pp. turned red by light.

URSONE $\text{C}_8\text{H}_9\text{O}_3$ 2aq. [265°] (Gintl, *M.* 14, 255). Occurs in the leaves of the red bear-berry (*Arctostaphylos Uva-ursi*) (Trommsdorff, *Ar. Ph.* [2] 80, 273; Hlasiwetz, *J. pr.* 64, 123). Needles, insol. water, acids, and alkalis, sl. sol. alcohol and ether. Conc. H_2SO_4 added to its solution in Ac_2O gives a red colour, changing through blue to green. Does not react with hydroxylamine or phenyl-hydrazine. Reduced by HI and F at 360° to C_8H_{12} (256°-267°).

Acetyl derivative [264°].

Benzoyl derivative [214°].

URUSHIC ACID $C_{11}H_{10}O_2$. S.G. 25° -985. Occurs in urushi or Japanese lacquer (Yoshida, *C. J.* 43, 472). Dark, pasty mass, v. sol. benzene and ether, insol. water. Br in CS_2 forms $C_{11}H_{12}Br_2O_2$. HNO_3 forms $C_{11}H_{10}(NO_2)_2O_2$, which forms FeA' . Chromic acid mixture forms oxyurushic acid $C_{11}H_{10}O_4$.— PbA'_2 (dried at 100°). [110°–115°]. Flocculent pp.— $FeH_2A'_{12}2aq$.— $FeH_2A'_2$. Deep-black pp.

USNETIC ACID $C_9H_8O_2$. [172°]. Occurs in small quantity, together with usnic acid, in the lichen *Usnea barbata* (Hesse, *B.* 10, 1326). Flat prisms (from alcohol), v. sol. ether. $FeCl_3$ colours its alcoholic solution bluish-violet. Bleaching-powder does not colour its alkaline solution. Is perhaps identical with decarbusnic.

USNIC ACID $C_{11}H_{10}O_2$ (Salkowski; Paterno) or $C_{11}H_{10}O_2$ (Hesse), or $C_{11}H_{10}O_2$ (Stenhouse a. Groves, *C. J.* 39, 234). *Carbusnic acid*. [195°–4° cor.]. S. (ether) 3 at 20°. Occurs in the lichens *Usnea barbata*, *Usnea florida*, *Zeora sordida* (Knop, *A.* 49, 103; Rochleder a. Heldt, *A.* 48, 12; Thomson, *A.* 53, 252; Stenhouse, *Pr.* 18, 222; *A.* 68, 97, 114; 155, 51; Hesse, *A.* 117, 343; Paterno, *G.* 8, 225; Salkowski, *B.* 8, 1459). Sulphur-yellow monoclinic crystals, sl. sol. alcohol, v. sol. hot ether and benzene. Does not yield betorcin when heated. Conc. H_2SO_4 forms usnetic acid $C_{22}H_{20}O_6$ [213°] crystallising in small yellowish prisms (Stenhouse a. Groves, *C. J.* 39, 236). When it is heated with an alcoholic solution of aniline it yields the anilide $C_{18}H_{16}O_4(NHPh)$, crystallising from alcohol in pale-yellow plates [171°], and forming in KOHAq a yellow solution from which HCl ppts. $C_{22}H_{22}NO_6$ [171°].

Salts.— $NaC_{11}H_9O_2$ 2aq (Spica, *G.* 12, 432). Pale-yellow, silky needles.— $KC_{11}H_9O_2$ 3aq or $KO_{11}H_9O_2$ 3aq. Pale-yellow plates (from 50 p.c. alcohol) (Hesse, *B.* 10, 1325).— $KC_{11}H_9O_2$ aq or $KO_{11}H_9O_2$ aq. Yellow prisms (from 93 p.c. alcohol).— CuA'_2 : green pp.

Decarbusnic acid $C_{11}H_{10}O_2$. [175°]. Formed by heating usnic acid (1 pt.) with alcohol (3½ pts.) at 160° (Paterno, *G.* 12, 234). Yellow, silky needles, sol. hot alcohol, sl. sol. water and ether. Not coloured by $FeCl_3$. Not attacked by $AcCl$. Reduces warm ammoniacal $AgNO_3$. Boiling KOHAq in absence of air splits it up into HOAc and decarbusnic acid $C_{11}H_{10}O_2$, which crystallises from alcohol in lemon-yellow prisms [199°] and yields, when boiled with Ac_2O , two acetyl derivatives $C_{11}H_{10}AcO_2$ [148°] (isomeric with decarbusanin) and $C_{11}H_{10}Ac_2O_2$ [131°].

Pyrousnetic acid $C_{11}H_{10}O_3$ (P); $C_9H_8O_4$ (Salkowski, *B.* 8, 1461). [197°]. Formed, together with pyrousnetic acid, by boiling usnic acid (2 pts.) with KOH (5 pts.) and water (5 pts.) in an atmosphere of hydrogen (Paterno, *G.* 6, 113; 12,

242). Shining scales (from ether), v. sol. alcohol, sl. sol. ether. Its alkaline solution absorbs oxygen from the air, turning green and ultimately brown. Reduces ammoniacal $AgNO_3$ readily. Ac_2O yields an acetyl derivative [205°]. Alcohol and HCl form an ether [147°]. Pyrousnetic acid is split up on dry distillation in a current of H into CO_2 and usneole $C_{11}H_{10}O_3$, which crystallises from alcohol in yellow prismatic tablets [176°] and is converted by $AcCl$ into a di-acetyl derivative [142°].

Pyrousnetic acid $C_{11}H_{10}O_3$, i.e. $C_{11}H_{10}O_3(CO_2H)$. [186°]. Formed by boiling usnic acid (10 pts.) with KOH (25 pts.) and water (25 pts.) for 15 minutes (Paterno, *G.* 12, 238). Colourless plates or needles (from alcohol). Ac_2O yields $C_{11}H_{10}AcO_3$ [168°]. When heated in a current of H, pyrousnetic acid is split up into CO_2 and usnetole $C_{11}H_{10}O_3$, which crystallises from dilute alcohol in yellowish needles [179°].

(8)-Usnic acid v. CLADONIC ACID.

UVIC ACID v. PYROTITRITIC ACID.

UVINONE $C_{11}H_{12}O_4$, i.e.

$O \begin{matrix} \diagup \\ \diagdown \end{matrix} \begin{matrix} CMe:C.CO.C:CM \\ CMe:C.CO.C:CM \end{matrix} O$ (?) [247°]. Formed, to the extent of 2 p.c., by distilling pyrotitric acid (Dietrich a. Paal, *B.* 20, 1086). Yellow needles (by sublimation), sol. HOAc, v. sl. sol. alcohol. Conc. H_2SO_4 forms a solution with green fluorescence. Br at 100° forms crystalline $C_{11}H_{12}Br_2O_4$.

UVITIC ACID $C_9H_8O_4$, i.e.

$C_9H_8Me(CO_2H)_2$ [1:3:5]. *Mesidic acid*. Mol. w. 180. [288°]. H.C.v. and p. 928,900. H.F. 193,100 (Stohmann, *J. pr.* [2] 40, 128). Formed, together with uvitonic acid, by boiling pyruvic acid with baryta-water (Finck, *A.* 122, 184). Formed also by oxidation of mesitylene or mesitylenic acid (Fittig a. Von Furtenbach, *Z.* [2] 4, 1; *A.* 147, 295), by oxidation of di-methyl-ethyl-benzene (Wroblewski, *A.* 192, 217), and by heating $C_9H_8Me(SO_2NH_2)(CO_2H)_2$ with conc. $HClAq$ at 230° (Hall a. Remsen, *Am.* 2, 136). Slender needles (from water), v. sl. sol. hot water, m. sol. alcohol and ether. Yields toluene on heating with soda-lime (Baeyer, *Z.* [2] 4, 119). The Ca salt heated with lime yields m-toluic acid (Böttinger a. Ramsay, *A.* 168, 255). Chromic acid mixture oxidises it to trimelic acid.

Salts.— K_2A'' : plates (from alcohol), v. sol. water.— BaA'' aq.— CaA'' aq.— Ag_2A'' . Nearly insol. cold water.

Ethyl ether Et.A''. [35°]. Crystalline.

References.—AMIDO-, BROMO-, NITRO-, and OXY-UVITIC ACID.

Isouvitic acid v. CARBOXY-PHENYL-ACETIC ACID.

Uvitic acid v. METHYL-PYRIDINE-DICARBOXYLIC ACID.

V

VALERAL v. VALERIC ALDEHYDE.

VALERAL-DI-ACETONAMINE v. *Pentylidene di-ACETONAMINE*.

VALERALDINE $C_{11}H_{21}NS_2$. *Thiovaleraldine*.

[41°]. Formed by the action of H_2S on isovaleric aldehyde ammonia suspended in water (Beisenhertz, *A.* 90, 109; Parkinson, *A.* 90, 119). Formed also from thio-isovaleric aldehyde and dry NH_3 (Schröder, *B.* 4, 468). Plates (from

ether), with powerful smell, sol. alcohol, insol. water.—B'HCl. Needles, sol. water.

VALERCREATININ v. METHYL-GUANIDO-VALERIC ACID.

VALERIAN OIL. An essential oil obtained from the root of *Valeriana officinalis*. It contains a terpene $C_{10}H_{16}$ (156°) $[\alpha]_D = -21^\circ$, a camphene, borneol $C_{10}H_{18}O$, di-bornyl oxide ($C_{10}H_{18}$)₂O (285°–290°), formyl-, acetyl-, and valeryl-borneol, and a little valeric acid (Gerhardt, *A. Ch.* [3] 7, 275; Pierlot, *A. Ch.* [3] 56, 291; Bruylants, *J. Ph.* [4] 27, 349; *B.* 11, 452; Haller, *C. R.* 103, 151; Oliviero, *C. R.* 117, 1096).

n-VALERIC ACID $C_5H_{10}O_2$ i.e. $CH_3 \cdot CH_2 \cdot CH_2 \cdot CH_2 \cdot CO_2H$. Mol. w. 102. (186° cor.). S.G. $\frac{2}{3}$.9562 (Zander, *A.* 224, 65); $\frac{15}{16}$.9446; $\frac{15}{16}$.9375 (Perkin); $\frac{20}{21}$.9298 (Brühl). C.E. (0°–10°) .00098 (Z.). S. 3.5 at 16°. S.V. 130.0 (Z.). M.M. 5.51. at 13°. $\mu_p = 1.4093$. $R_\infty = 43.16$ (Brühl). H.F. 137,800 (Stohmann, *J. pr.* [2] 49, 99). Occurs in crude wood vinegar (Grodzki a. Krämer, *B.* 11, 1358).

Formation.—1. By saponifying its nitrile (*n*-butyl cyanide) (Lieben a. Rossi, *A.* 159, 58; *G.* 1, 239).—2. By oxidation of *n*-amyl alcohol (L. a. R.).—3. By the action of metallic silver on a mixture of EtI and β -iodopropionic acid (W. von Schneider, *Z.* [2] 5, 343).—4. By oxidising α -oxy-*n*-caproic acid (Erlenmeyer, *B.* 9, 1840).—5. By heating β -acetyl-propionic acid with HI and P at 200° (Kehrer a. Tollens, *A.* 206, 233).—6. By reducing β -acetyl-propionic acid with sodium-amalgam (Wolff, *A.* 208, 110).—7. By heating *n*-propyl-malonic acid at 180° (Juslin, *B.* 17, 2504; Furth, *M.* 9, 308).—8. By fermentation of calcium lactate (Fitz, *B.* 13, 1309; 14, 1084). 9. By heating the lactone of γ -oxy-*n*-valeric acid with HIAq and P at 240° (Fittig, *A.* 226, 346).—10. A product of oxidation of castor oil by dilute HNO_3 (Wahlforss, *B.* 22 Ref., 438).

Properties.—Liquid, smelling like butyric acid.

Salts.—KA'. Plates (from alcohol).—CaA'₂ aq. S. 10.267 at 0°; 8.144 at 60°. Least soluble at 60°–70° (F.).—CaA'₂ 1½aq (Schorlemmer, *A.* 161, 270).—BaA'. S. 21.693 at 0°; 23.076 at 80°.—MnA'₂ aq.—CuA'₂: minute green needles. More sol. cold than hot water.—ZnA'₂. S. 2.6 at 25°.—AgA'. S. .229 at .3°; .641 at 70.5°.

Methyl ether MeA'. (127.3°). S.G. $\frac{0}{10}$.9097 (G.); $\frac{20}{21}$.8795. C.E. (0°–10°) .00106. S.V. 149.1 (Gartenmeister, *A.* 233, 273). $\mu_p = 1.3997$. $R_\infty = 50.7$.

Ethyl ether EtA'. Mol. w. 130. (144.7° cor.). S.G. $\frac{2}{3}$.8939 (G.); $\frac{20}{21}$.8765 (Lieben a. Rossi, *A.* 165, 117); $\frac{20}{21}$.8661 (Brühl). S.V. 174.3. C.E. (0°–10°) .00111. $\mu_p = 1.402$. $R_\infty = 58.08$ (B.).

n-Propyl ether PrA'. (167.5°). S.G. $\frac{2}{3}$.8888. C.E. (0°–10°) .00106 (G.). S.V. 197.8.

n-Butyl ether C₄H₉A'. (185.8°). S.G. $\frac{2}{3}$.8847. C.E. (0°–10°) .00101. S.V. 222.1.

n-Amyl ether C₅H₁₁A'. Mol. w. 172. (208.7°). S.G. $\frac{2}{3}$.8812 (G.); $\frac{20}{21}$.8568 (Brühl). C.E. (0°–10°) .00097. S.V. 245.8. $\mu_p = 1.417$. $R_\infty = 80.48$.

n-Heptyl ether C₇H₁₅A'. (223.8°). S.G. $\frac{2}{3}$.8797. C.E. (0°–10°) .00096. S.V. 272.0.

n-Heptyl ether C₇H₁₅A'. (248.6°). S.G. $\frac{2}{3}$.8786. C.E. (0°–10°) .00090. S.V. 297.4.

n-Octyl ether C₈H₁₇A'. (260.2°). S.G. $\frac{2}{3}$.8784. C.E. (0°–10°) .00088. S.V. 322.6.

Amide C₅H₉CO.NH₂. Mol. w. 101. [116°]. Pearly plates (Weidel a. Ciamician, *B.* 13, 69). V. sol. water, alcohol, and ether.

Nitrile C₅H₉CN. **n-Butyl cyanide.** (140°). S.G. $\frac{2}{3}$.816 (Lieben a. Rossi, *A.* 158, 171). Formed, together with amylamine, by allowing a mixture of hexoic amide (1 mol.) and bromine (2 mols.) to run into a 10 p.c. solution of NaOH (Hofmann, *B.* 17, 1410).

Isovaleric acid (CH₃)₂CH.CH₂.CO₂H. **Isopropyl-acetic acid.** (176° cor.). S.G. $\frac{15}{16}$.9336; $\frac{20}{21}$.9261 (Perkin); $\frac{20}{21}$.931 (E. a. H.). M.M. 5.685 at 16°. S. 4.24 at 20°.

Vapour tension: Richardson, *C. J.* 49, 767.

Heat of neutralisation: Gal a. Werner, *Bl.* [2] 46, 801.

Occurs in the fat of *Delphinium Phocæna* (Chevreul [1817], *Corps gras*, pp. 99, 209), in valerian root (Grote, *B.* J. 11, 225; Trommsdorff a. Ettling, *A.* 4, 229; 6, 176), in the root of *Angelica Archangelica* (Meyer a. Zenner, *A.* 55, 328), in the root of *Athamanta Oreo-selinum*, in the bark of the alder tree, in the berries and bark of the Guelder rose (*Viburnum Opulus*) (Moro, *A.* 55, 330), in the root of *Viburnum prunifolium* (Allen, *Ph.* [3] 11, 413), and in oil of geranium (O. Jacobsen, *A.* 157, 232). A valeric acid occurs in rosin oil (Lwoff, *B.* 20, 1017) and in yolk of wool (suint) (Buisine, *Bl.* [2] 48, 639).

Formation.—1. By oxidation of inactive fermentation amyl alcohol (Dumas a. Stas, *A.* 33, 156; 35, 143; Erlenmeyer a. Hell, *A.* 160, 257; Pedler, *C. J.* 21, 74).—2. By boiling its nitrile with alcoholic potash (E. a. H.; Schmidt a. Sachtleben, *A.* 193, 87).—3. Together with the active acid by oxidation of leucine (amido-hexoic acid) (E. a. H., cf. Neubauer, *A.* 106, 59).—4. By heating isopropyl-malonic acid at 180° (*B.* 11, 596).—5. By oxidising di-methyl-allyl-carbinol, treating the resulting CMe₂(OH).CH₂.CO₂H with HI, and reducing the β -iodo-valeric acid so formed by means of 3 p.c. sodium-amalgam applied in an acid solution (Schirokoff, *J. pr.* [2] 23, 286).—6. By the action of KOH or HClAq on *Athamantin* (Schneidermann a. Winckler, *A.* 51, 324).—7. By putrefactive fermentation of proteids (Ijkeno, *A.* 63, 269).—8. By the action of CrO₃ on gelatin and albumen (Schlieper, *A.* 59, 7; Guckelberger, *A.* 64, 71).—9. From isopropyl-aceto-acetic ether (Frankland a. Duppa, *A.* 145, 84).—10. By distilling isopropyl-malonic acid (Conrad a. Bischoff, *A.* 204, 151).—11. A product of distillation of colophony (Renard, *A. Ch.* [6] 1, 253).

Preparation.—1. **Isoamyl alcohol** is oxidised by less than the calculated quantity of KMnO₄ in the cold. Some acetic acid is formed, but this can be got rid of by distilling a dilute solution of the acids, for valeric acid passes over in the first quarter of the distillate, the acetic acid remaining behind (Duclaux, *C. R.* 105, 171).—2. By oxidising isoamyl alcohol (1,000 c.c.) with K₂Cr₂O₇ (1,000 g.) dissolved in water (8,500 c.c.) by adding in the cold H₂SO₄ (1,400 g.) mixed with water (800 g.). The resulting isoamyl isovalerate is saponified by potash (Pierre a. Puchot, *A. Ch.* [4] 29, 229).—3. By

distilling valerian root with dilute phosphoric acid, neutralising the distillate with Na_2CO_3 , and decomposing the resulting Na salt by H_2SO_4 . In purifying valeric acid use may be made of the fact that the acid forms crystalline acid salts with K and Na (Lescœur, *Bl.* [2] 27, 104).

Properties.—Liquid, inactive to light. Its smell is powerful and unpleasant. Sl. sol. water. Separated from aqueous solution by CaCl_2 . Volatile with steam. Mixes with alcohol and ether. It is set free from its salts by mineral acids, by HOAc , by oxalic, tartaric, citric, and malic acids, but not by butyric acid. When conc. valeric acid is added to a solution of cupric acetate, anhydrous cupric valerate separates in oily drops, which soon change to a greenish-blue crystalline powder of the hydrated salt; butyric acid would at once give a crystalline pp. (Larocque a. Huraut, *J. Ph.* [3] 9, 430).

Reactions.—1. Oxidised by chromic acid mixture at 20° to acetic acid and CO_2 .—2. Boiling dilute HNO_3 forms nitro-valeric acid, methyl-malic acid, and a little di-nitro-propane (when prepared from valerian) or di-nitro-butane (when prepared from isoamyl alcohol) (Bredt, *B.* 14, 1782; 15, 2319; cf. Dessaignes, *A.* 79, 374).—3. Dilute alkaline KMnO_4 forms $\text{CMe}_2(\text{OH})\cdot\text{CH}_2\cdot\text{CO}_2\text{H}$.—4. Electrolysis of the K salt in conc. solution yields octane C_8H_{18} (Kolbe, *A.* 69, 259).—5. Passed through a red-hot tube it yields ethylene, propylene, butylene, and other hydrocarbons (Hofmann, *C. J.* 3, 121). 6. The Ca salt yields di-isobutyl ketone on distillation by itself, valeric aldehyde on distillation with calcium formate, and methyl isobutyl ketone on distillation with calcium acetate.

Salts.— $\text{NH}_4\text{A}'$. V. sol. water and alcohol. — $(\text{NH}_4)_2\text{H}_2\text{A}'_2$. — KA' . Deliquescent crystalline mass. S. (alcohol) 26 at 20° . [140°]. — $\text{LiA}'\frac{1}{2}\text{aq}$. Nodules. — TlA' . V. sol. water. — CaA'_2 3aq: needles (Barone, *A.* 165, 120; Schmidt a. Sachtleben, *A.* 193, 87; Schirokoff, *J. pr.* [2] 23, 286). S. 18.4 at 0° (Sedlitzky, *M.* 8, 563). — CaA'_2 4aq. — CaA'_2 5aq. — BaA'_2 . Triclinic plates. S. 94 at 18° . S. (alcohol) 3:3 at 20° . — BaA'_2 3aq. — BaA'_2 2aq. — SrA'_2 . — MnA'_2 2aq. — ZnA'_2 2aq. Crystalline. — ZnA'_2 . S. 1 in the cold. S. (80 p.c. alcohol) 1.7 in the cold; S. (ether) .2 in the cold; .5 at 35° (Wittstein, *J.* 1847, 557). — ZnA'_2 12aq. — ZnA'_2 3aq. — ZnA'_2 2 NH_3 (Lutschak, *B.* 5, 30). — CuA'_2 . Green crystalline pp. — CuA'_2 3aq. — $\text{BiA}'_2(\text{OH})_2\text{O}_2$ (Schuch, *Ar. Ph.* [3] 2, 97). — FeA'_2 . — $\text{FeA}'_2(\text{OH})_2$. — PbA'_2 : easily fusible laminæ. — $\text{PbA}'_2\text{O}_2$. Groups of needles, sl. sol. water. — AgA' . S. 177 at 0° (Sedlitzky); 185 at 20° (Erlenmeyer).

Methyl ether MeA' . (116°). S.G. $\frac{2}{9007}$. C.E. (0° – 10°) .001174. S.V. 149.6 (Elsässer, *A.* 218, 315); 148.8 (R. Schiff, *A.* 220, 334). S.H. (21° – 45°) .491 (Kopp). Smells like bananas.

Ethyl ether EtA' . (134°). (E.); (185° cor.) (Perkin). S.G. $\frac{2}{8851}$ (E.); $\frac{1}{8714}$; $\frac{2}{8632}$ (P.). C.E. (0° – 10°) .001034. S.V. 173.4 (E.); 173.0 (S.). M.M. 7.615 at 18° . Oil, sol. alcohol. Smells like rennet apples and water-mint (Pierre a. Puchot, *A. Ch.* [4] 20, 284). Converted by sodium into oxy-decic acid, ethyl ethoxy-decote (Hantzsch, *A.* 249,

64), an acid $\text{C}_{10}\text{H}_{18}\text{O}_2$ [α . 127°] (295°), and other bodies (Greiner, *Z.* [2] 2, 460; Wanklyn, *C. J.* 17, 371; Geuther a. Greiner, *J.* 1865, 319).

n-Propyl ether PrA' . (166°). S.G. $\frac{2}{8809}$. C.E. (0° – 10°) .000997. S.V. 197.5 (Elsässer); 196.8 (Schiff).

Isopropyl ether PrA' . (142°). S.G. $\frac{2}{870}$; $\frac{1}{854}$ (Silva, *A.* 153, 136).

Di-chloro-propyl ether $\text{C}_3\text{H}_5\text{Cl}_2\text{A}'$. (245°) at 737 mm. S.G. $\frac{1}{1149}$. Formed from epichlorhydrin and isovaleryl chloride (Truchot, *A.* 138, 298).

Isobutyl ether $\text{C}_4\text{H}_9\text{A}'$. (169°) (Elsässer, *A.* 218, 328); (173°) (P. a. P.). S.G. $\frac{2}{8736}$ (E.). $\frac{2}{8884}$ (P. a. P.). C.E. (0° – 10°) .001027. S.V. 223.4 (E.).

Isoamyl ether $\text{C}_5\text{H}_{11}\text{A}'$. (188°) (Kopp; R. Schiff, *A.* 234, 344); (196°) (Balard); (190°) (Balbiano, *J.* 1876, 348); (194°) (Kahlbaum). S.G. $\frac{2}{870}$ (Balbian). S.V. 244.5. V.D. 6.1. Smells, when dissolved in alcohol (7 pts.), like apples.

Octyl ether $\text{C}_8\text{H}_{17}\text{A}'$. (250°). S.G. $\frac{1}{862}$ (Zincke, *A.* 152, 6).

Cetyl ether $\text{C}_{16}\text{H}_{33}\text{A}'$. [25°]. (280° – 290°) at 202 mm. S.G. $\frac{2}{852}$ (Dollfus, *A.* 131, 233).

Allyl ether $\text{C}_3\text{H}_5\text{A}'$. (154°). Oil (Cahours a. Hofmann, *A.* 102, 296).

Glyceryl derivative v. GLYCERIN.

Chloride $\text{Pr}\cdot\text{CH}_2\cdot\text{COCl}$. (114°) at 726 mm. S.G. $\frac{2}{9887}$. μ_D 1.4213. R_∞ 49.14. Liquid, easily decomposed by water (Béchamp, *C. R.* 42, 224; Brühl, *A.* 203, 24).

Bromide $\text{C}_3\text{H}_5\text{OBr}$. (143°). Liquid.

Iodide $\text{C}_3\text{H}_5\text{OI}$. (168°) (Cahours, *C. R.* 44, 1252).

Anhydride $(\text{C}_5\text{H}_9\text{O})_2\text{O}$. Mol. w. 186. (215°) (Chiozza, *A.* 84, 106). Converted by hydrated BaO into the oily peroxide $(\text{C}_5\text{H}_9\text{O})_2\text{O}_2$ (Brodie, *Pr.* 12, 655).

Aceto-valeric anhydride $(\text{C}_5\text{H}_9\text{O})_2\text{OAc}$. (147° – 160°) (Autenrieth, *B.* 20, 3187).

Amide $\text{C}_5\text{H}_9\text{CONH}_2$. [128°] (Letts, *B.* 5, 669; Hofmann, *B.* 15, 982); [135°] (Schmidt a. Sachtleben, *A.* 193, 102). (231°). Silky plates, v. sol. water and alcohol.

Anilide $\text{C}_5\text{H}_9\text{CO}\cdot\text{NHPh}$. [115°] (Chiozza, *A. Ch.* [3] 39, 201; Kelbe, *B.* 16, 1200; cf. Dumas, *C. R.* 25, 475, 658; Dessaignes, *A.* 63, 333). Sl. sol. hot water, v. sol. alcohol and ether.

Nitrile $\text{Pr}\cdot\text{CH}_2\cdot\text{CN}$. **Isobutyl cyanide**. Mol. w. 83. (129°) (R. Schiff, *B.* 19, 567). S.G. $\frac{2}{823}$. V.D. 2.89. Formed by heating ammonium valerate or valeramide with P_2O_5 (Dumas, Malaguti a. Leblanc, *C. R.* 25, 658). Occurs among the products of oxidation of gelatin and casein by chromic acid mixture (Schlieper, *A.* 59, 15; Guckelberger, *A.* 64, 72), of the action of chlorine on leucine (Schwanert, *A.* 102, 228), and of the action of conc. HNO_3 on castor oil (Hell a. Kitrosky, *B.* 24, 980). Formed also, together with valeramide, by heating valeric acid with potassium sulphocyanide (Letts, *B.* 5, 669). It is also got by the action of cold Ac_2O on the oxim of valeric aldehyde (Dollfus, *E.* 25, 1915). Prepared by digesting isobutyl iodide with KC_y and alcohol (Erlenmeyer a. Hell, *A.* 160, 266). Liquid, smelling like almonds dissolving in about four times its volume of water.

Sodium converts it, on heating, into cyanbutine C_4H_7N , crystallising in stellate groups of needles, which yield $BHCl$ and $B'H_2PtCl_6$, and is converted by nitrous acid into $C_4H_7(OH)N_2$ [89°] (E. von Meyer, *J. pr.* [2] 37, 407).

Active valeric acid $CHMeEt.CO_2H$. *Methyl-ethyl-acetic acid*. *Hydrotiglic acid*. (177° i.V.). S.G. $\frac{24}{17.5}$.938 (Saur). S.V. 129.1 (Lossen, *A.* 254, 60). Occurs in the essential oil from the fruit of *Angelica Archangelica* (R. Müller, *B.* 14, 2476).

Formation.—1. By oxidation of isoamyl alcohol.—2. By reducing tiglic acid with HI and P (Schmidt a. Berendes, *A.* 191, 117).—3. By heating methyl-ethyl-malonic acid (Bischoff a. Conrad, *A.* 204, 151).—4. From methyl-ethyl-acetoacetic ether (Saur, *A.* 188, 257).—5. By reducing angelic acid (Schmidt, *A.* 208, 261).—6. By reducing bromo-hydro-tiglic acid (Pagenstecher, *A.* 195, 111).—7. By the action of $NaOEt$ and EtI on propionyl-propionic acid (Israel, *A.* 231, 219).—8. By oxidation of the corresponding aldehyde (Lieben a. Zeisel, *M.* 7, 56).

Properties.—The acid obtained by synthetic methods is inactive, but when obtained by oxidation of active amyl alcohol it is dextro-rotatory, but is mixed with inactive isovaleric acid. By oxidation of an amyl alcohol $[a]_D = -4.4^\circ$ Guye and Chavanne (*C. R.* 116, 1454) obtained a valeric acid (174°), $[a]_D = +13.6^\circ$, S.G. $\frac{22}{25}$.938. By oxidation of an amyl alcohol $[a]_D = -5.2^\circ$ at 22° Rogers (*C. J.* 63, 1130) got a valeric acid (175°), S.G. $\frac{22}{25}$.936, $[a]_D = +13.9^\circ$ at 22°. Methyl-ethyl-acetic acid can be separated from isopropyl-acetic acid through the greater solubility of its silver salt. Dilute $KMnO_4$ oxidises methyl-ethyl-acetic acid to $CMeEt(OH).CO_2H$.

Salts.— CaA'_2 5aq: needles. S. (of CaA'_2) 29.— BaA'_2 : gummy mass.— ZnA'_2 : Needles, more sol. cold than hot water.— CuA'_2 : bluish-green, crystalline pp.— AgA' : groups of needles. S. 1:13 at 20° (C. a. B.); 1:11 at 1° (Sedlitzky, *M. S.* 6, 568).

Ethyl ether EtA' . (133.5° i.V.). S.G. $\frac{20}{17.5}$.8695.

Nitrile C_4H_7N . (125°). S.G. $\frac{2}{2}$.8061. Formed by adding Na and EtI to a solution of acetonitrile in benzene (Hanriot a. Bouveault, *Bl.* [2] 51, 173). Liquid.

Valeric acid $CHMe.CO_2H$. *Tri-methyl-acetic acid*. [35°]. (163.5° i.V.). S.G. $\frac{22}{25}$.905. S. 2:2 at 20°. *Heat of neutralisation*: Gal a. Werner, *Bl.* [2] 46, 801. Formed by heating its nitrile with alcoholic potash or conc. $HClAq$ at 100° (Butleroff, *A.* 165, 322; 170, 151; 173, 355; *B.* 5, 478). Formed also by action of CrO_3 on pinacolin (Friedel a. Silva, *B.* 6, 146, 826) and on tri-methyl-pyruvic acid (Glücksman, *M.* 10, 777). Monometric crystals. Does not yield a bromo-derivative on heating with Br , either alone or in presence of P (Reformatsky, *B.* 23, 1596).

Salts.— NaA'_2 2aq. Prisms, v. sol. water.— KHA'_2 : Needles, m. sol. water.— CaA'_2 5aq.— CaA'_2 4aq. S. 7 at 1°.— SrA'_2 5aq.— BaA'_2 5aq. S. 84 at 2° (Landau, *M.* 14, 707).— MgA'_2 8aq.— ZnA'_2 2aq. S. (of ZnA'_2) 1:7 at 20°. The cold saturated solution becomes filled on warming

with a solid salt, which dissolves up again on cooling.— PbA'_2 — $PbHA'$: needles.— CuA' aq: greenish pp.— AgA' . S. 1:1 at 1°; 1:27 at 27° (Stiasny, *M.* 12, 599).

Methylether MeA' . (101°) (Butleroff). *Ethyl ether* EtA' . (118.5° i.V.). S.G. $\frac{20}{17.5}$.875.

Tert-butylether C_4H_9A' . (135° i.V.). *Amyl ether* CM_2CH_2A' . (165°) (Tissier, *Bl.* [2] 24, 558).

Chloride $CM_2.COCl$. (106°). *Anhydride* $(CM_2.CO)_2O$. (190°). *Amide* $CM_2.CO.NH_2$. [154°]. (212°).

Formed by heating the ammonium salt in sealed tubes at 230° (Franchimont a. Klobbie, *R. T. C.* 6, 238). Long needles. Decomposed by pure HNO_3 (S.G. 1:53) with evolution of N_2O .

Methylamide $CM_2.CO.NHMe$. [91°]. (204°).

Dimethylamide $CM_2.CO.NMe_2$. (186°).

Ethylamide $CM_2.CO.NHEt$. [49°]. (204°).

Diethylamide $CM_2.CO.NEt_2$. (203°). S.G. $\frac{15}{15}$.891.

Nitrile $CM_2.CN$. *Tert-butyl cyanide*. [16°]. (106°). Formed, together with a polymeride (160°), by the action of tert-butyl iodide on dry potassio-mercuric cyanide below 5° (Butleroff, *A.* 170, 151; Freund a. Lenze, *B.* 23, 2866; 24, 2161). Crystalline mass with pungent smell. On heating with aniline hydrochloride it yields phenyl-valeramide, which forms an oxalate [192°]. Hydroxylamine forms the amidoxim $CM_2.C(NH_2).NOH$ [116°].

References.—AMINO-, BROMO-, CHLORO-, IODO-, NITRO-, NITROSO-, AND OXY-VALERIC ACIDS.

n-VALERIC ALDEHYDE

$CH_3.CH_2.CH_2.CH_2.CHO$. (103°). S.G. $\frac{11}{11}$.819. Formed by distilling calcium *n*-valerate with calcium formate (Lieben a. Rossi, *A.* 159, 70; Zander, *A.* 224, 81).

Isovaleric aldehyde $(CH_3)_2CH.CH_2.CHO$. *Valeral*. Mol. w. 86. (92.5°). S.G. $\frac{11}{11}$.8041; $\frac{25}{25}$.7961 (Perkin, *C. J.* 45, 477). μ_s 1.3934. R_{20} 40.66 (Brühl). V.D. 43.06 (calc. 43) (Schröder, *B.* 4, 400, 468). S.V. 118.5. Formed by oxidation of isoamyl alcohol (Dumas a. Stas, *A. Ch.* [2] 73, 145; Parkinson, *A.* 90, 114; Kolbe a. Guthrie, *A.* 109, 296). Formed also by distilling calcium iso-valerate with calcium formate (Limpricht, *A.* 97, 370), by the distillation of isovalerates (Chancel, *A.* 60, 318; Ebersbach, *A.* 106, 262; Schmidt, *B.* 5, 600), by oxidation of gluten (Keller, *A.* 72, 34) and castor oil (Arzbächer, *A.* 73, 202), and by the action of SO_2 on leucine (Schwanert, *A.* 102, 226).

Properties.—Neutral oil, with pungent fruity odour. Polymerises on keeping. Mixes with alcohol and ether. On heating with ammonium sulphocyanide it yields a dark-red liquid, sol. alcohol, ether, and $HOAc$ (Brodsky, *M.* 8, 87). Alkaline sodium nitroprusside gives a violet-red colour, destroyed by $HOAc$ (Von Bitto, *A.* 267, 376). Combines with sodium bisulphite, forming $(C_5H_9O)NaHSO_3$.

Reactions.—1. Readily oxidised to valeric acid.—2. *Chlorine* forms mono- and di-chloro-valeric aldehydes, and, at 140°, oily $C_5H_9Cl_2O$ (204°), which is converted by alcoholic soda into $C_5H_9Cl_2O$ (209°).—3. PCl_5 forms $C_5H_9Cl_2$.—4. *Potash-fusion* gives valeric acid.—5. Heating with lime forms isoamyl alcohol, calcium

valerate and other bodies (Fittig, *A.* 117, 68).—6. *Sodium-amalgam* and water slowly form isoamyl alcohol (Wurtz, *A.* 184, 201).—7. *Sodium* forms isoamyl alcohol, sodium valerate, decyl alcohol $C_{10}H_{22}O$ (203°), an oil $(C_{10}H_{21}O)_n$ (250°–290°), the compound $C_{20}H_{42}O_n$, and the acid $C_{10}H_{20}O_2$ (Borodin, *Z.* 1864, 353; *B.* 5, 480).—8. KOH at 0° produces an oily polymeride, lighter than water, not capable of combining with $NaHSO_4$, and yielding isovaleric aldehyde and the compounds $C_{10}H_{20}O$ and $C_{20}H_{42}O_2$ on distillation (Borodin, *B.* 6, 982). This polymeride, left in contact with Na_2CO_3 Aq, often forms needles of $C_{20}H_{42}O_2$ [70°].—9. Heating with KOH forms the aldehyde $C_{10}H_{20}O$ and a compound $C_{20}H_{42}O_2$ (260°–290°). S.G. .90.—10. Heating with *zinc* at 180° forms decenoic aldehyde $C_{10}H_{18}O$ (190°), S.G. .862 (Riban, *C. R.* 75, 96; Kekulé, *A.* 162, 77) and other products.—11. $ZnEt_2$ produces the oil $(C_{10}H_{18}O)_n$ in large quantity (Beilstein *A.* Rieth, *A.* 126, 242). $ZnMe_2$, followed by water, forms methyl-isobutylcarbinol (Kuvsinoff, *J. R.* 1887, 204).—12. Dry K_2CO_3 at 50° forms an oily polymeride, which is reconverted at 180° into the aldehyde. Boiling with K_2CO_3 yields $C_{10}H_{18}O$ (*v. supra*), $C_{20}H_{42}O_2$ (265°–270°), and $C_{15}H_{32}O_2$ (235°–240°) (Gäss *a.* Hall, *B.* 8, 369).—13. Dry K_2CO_3 added to moist isovaleric aldehyde forms, after some days, crystals of a polymeride [84°], which is reconverted at 108° into the original aldehyde (Bruylants, *B.* 8, 414).—14. PH_4I forms a compound $(C_4H_9O)_2PH_4I$, crystallising from ether in plates [119°], converted by cold potash into $(C_4H_9O)_2PH_4OH$, crystallising in prisms [125°], insol. water (De Girard, *A. Ch.* [6] 2, 33; *C. R.* 94, 215).—15. On heating with *hypophosphorous acid* in an atmosphere of hydrogen the compound $(C_4H_9O)_2H_3PO_2$ [160°] is formed. It yields BaA_2 aq (Ville, *C. R.* 109, 71).—16. $AcCl$ at 100° combines, forming chloro-amyl acetate $C_5H_{11}CHCl.OAc$ (Maxwell Simpson, *Pr.* 27, 120).—17. *m-Amido-benzoic acid* forms $C_5H_{11}NO_2$ [c. 130°].—18. Dry HCl forms $(C_4H_9CHCl)_2O$ (180°) (Bruylants, *B.* 8, 414).—19. Conc. NH_3 Aq forms isovaleric aldehyde-*ammonia* $C_4H_9CH(NH_2)OH$ 7aq [58°] (Erdmann, *A.* 130, 211; Petersen, *A.* 132, 158; Ljubavin, *B.* 6, 1460), which yields, on allowing its alcoholic solution to stand, or on boiling with potash, the oily 'trioxymethylamine' $C_{11}H_{23}NO_3$, forming $B'HCl$ [113°] and $B'_2H_2PtCl_6$. $AgNO_3$ reacts with isovaleric aldehyde-*ammonia*, forming $(C_4H_9N)_2AgNO_3$ and $(C_4H_9N)_2AgNO_3$ (Goldschmidt, *B.* 11, 1200; Mixer, *J.* 1878, 488).—20. Alcoholic NH_3 at 150° forms valeritine, hydrovaleritine, and other bodies. Valeritine $C_{11}H_{21}N$ is a very unstable liquid (250°–260°), yielding $B'HHgCl_2$ [88°], $B'_4H_4PtCl_6$, and $B'_2C_4H_8N_2O$ [130°]. Hydrovaleritine $C_{11}H_{23}N$ or $C_{11}H_{21}N$ is a liquid, yielding crystalline $B'HCl$. S. 2-87 at 22°, not melted at 180° (Ljubavin, *B.* 6, 565).—21. H_2S passed into an aqueous solution forms thiovaleric aldehyde C_4H_9S [89°]. An isomeride (115°) is got, together with a polymeride [94-5°], by heating isovaleric aldehyde with sulphur at 250° (Barbaglia, *B.* 13, 1574; 17, 2654; *G.* 11, 95; 16, 426).—22. OS_2 and NH_3 Aq form carbovaleraldine $C_{11}H_{23}N_2S_2$ (Schröder, *B.* 4, 469; Mulder, *A.* 168, 237), which melts at 109°

(Guareschi, *A.* 222, 811).—23. $NH_2.OS.OEt$ and HCl form $C_4H_9(NH.OS.OEt)$, [108°] (Bischoff, *B.* 7, 1078).—24. H_2Se passed into an aqueous solution of valeric aldehyde forms C_4H_9Se [56-5°].—25. *Acetone* and dilute NaOH yield $Pr.CH_2.CH:CH.CO.CH_3$ (180°) (Barbier *a.* Bouveault, *C. R.* 118, 198).

Oxim $C_4H_9CH:NOH$. Mol. w. 101. (163°). S.G. .8934 (*in vacuo*). μ_D 1.487 (Petracek, *B.* 16, 829; Trapezonjanz, *B.* 26, 1428). It is a *syn*-oxim, because it yields valeritrile when mixed with Ac_2O and ether (Dollfus, *B.* 25, 1915).

Isovaleric orthaldehyde. *Amylidene glycol*. *Acetyl derivative* $C_4H_9CH(OAc)_2$ (195°). Formed by heating isovaleric aldehyde with Ac_2O at 200°.

Benzoyl derivative $C_4H_9CH(OBz)_2$ [111°]. (264°). Formed by heating the aldehyde with Bz_2O at 260° (Guthrie *a.* Kohe, *A.* 109, 298).

Di-methyl ether $C_4H_9CH(OMe)_2$ (124°). S.G. .852. Formed from isovaleric aldehyde (2 vols.), MeOH (5 vols.), and HOAc (1 vol.) (Alsberg, *J.* 1864, 486).

Di-ethyl ether $C_4H_9CH(OEt)_2$ (168°). S.G. .835. Formed in like manner.

Di-isoamyl ether $C_4H_9CH(OC_5H_{11})_2$ (c. 248°). S.G. .849.

Ethyl isoamyl ether $C_4H_9CH(OEt)(OC_5H_{11})$ (c. 205°). S.G. .875. Formed by the action of Na on an ethereal solution of isovaleric ether (Greiner, *Z.* 1866, 465).

Valeric aldehyde $CHMeEt.CHO$. (91°). Formed by reducing tiglic aldehyde with iron and HOAc (Herzig, *M.* 3, 123; Lieben *a.* Zeisel, *M.* 7, 56), and by warming $CH_2:CH.CHEt.OH$ with dilute (1 p.c.) H_2SO_4 (Kondakoff, *J. R.* 20, 154).

Valeric aldehyde $CMe_2.CHO$. [3°]. (75°). S.G. .7927 (Tissier, *B.* [2] 24, 558).

Di-isovaleric aldehyde *v.* DECENOIC ALDEHYDE.

Reference.—DI-BROMO-, CHLORO-, IODO-, and OXY-VALERIC ALDEHYDE.

VALEROGUANAMINE C_4H_9N , *i.s.*

$Pr.CH_2.C(NC(NH))>NH$. *Butylguanamine*.

[178°]. Formed by heating guanidine isovalerate (Bandrowski, *B.* 9, 240; Haaf, *J. pr.* [2] 48, 76). Flat plates (from water). Weak base.— $B'HCl$: needles, *v.* sol. water.— $B'_2H_2SO_4$.— $B'AgNO_3$.

VALEROLACTIDE *v.* OXY-VALERIC ACID.

VALEROLACTONE *v.* OXY-VALERIC ACID.

VALERONE *v.* DI-ISOBUTYL KETONE.

VALERONITRILE *v.* Nitrile of VALERIC ACID.

VALEROVALERIC ACID *v.* VALERYL-VALERIC ACID.

DIVALERYL C_4H_9O , *i.s.* $C_4H_9.CO.CO.C_4H_9$. (270°–280°). Formed by the action of Na on valeryl chloride (Brühl, *B.* 12, 815). Oil.

VALERYL-ACETOPHENONE *v.* PHENYL BUTYL METHYLENE KETONE.

VALERYL CHLORIDE *v.* Chloride of VALERIC ACID.

VALERYL-CYANAMIDE *v.* CYANIC ACIDS.

VALERYLENE *v.* PENTENES and also BROMO- and DI-CHLORO-VALERYLENE.

VALERYLENE TETRABROMIDE *v.* TETRABROMO-PENTANE.

VALERYLENE HYDRATE *v.* **PENTENZYL ALCOHOL.**

VALERYLENE HYDROCHLORIDE *v.* **CHLORO-AMYLENE.**

VALERYL-VALERIC ACID. *Ethyl ether* $C_{12}H_{22}O_4$, i.e. $CH_3Pr.CO.OHPr.CO.Et$. (206°) at 722 mm. Formed by the action of sodium on isovaleric ether (Greiner, *Z.* 1866, 461; Wohlbrück, *B.* 20, 2335). Oil, sol. alcohol and ether.

VALYLENE C_8H_8 . Mol. w. 66. (50°). A product of the action of alcoholic potash on valerylene dibromide (Reboul, *A.* 185, 372). Liquid, with odour of garlic and prussic acid. Ammoniacal Cu_2Cl_2 ppts. yellow C_8H_8Cu , which yields the pure hydrocarbon on treatment with dilute $HClAq$. Bromine at 0° forms crystalline $C_8H_8Br_2$. Ammoniacal $AgNO_3$ yields a white pp. of C_8H_8Ag .

VANADATES *v.* **VANADIUM OXYACIDS, AND SALTS AND DERIVATIVES THEREOF**, p. 851.

VANADIC ACIDS *v.* **VANADIUM OXYACIDS**, p. 851.

VANADIUM. *V.* At. w. 51.2. Mol. w. not known. Melts at a very high temperature; probably higher than m.p. of Mo, which does not melt at 1700° – 1800° (Moissan, *C. R.* 116, 1225). S.G. 5.5 at 15° (Roscoe, *T.* 1869, 679). For emission-spectrum, obtained by using electric sparks, *v.* Thalén (*A. Ch.* [4] 18, 243).

Historical.—In 1801 Del Rio announced the discovery of a new metal in a lead ore from Zimapán in Mexico (*G. A.* 71, 7); to this metal he gave the name *erythronium*, but at a later time he thought the metal was only impure chromium. In 1830 Sefström found a new element in the bar-iron and refinery slags where iron-ore from Taberg in Sweden was smelted (*P.* 21, 43); this element he called *vanadium* (from a Scandinavian deity *Vanadis*). In the same year (*P.* 21, 49) Wöhler found that the lead ore examined in 1801 by Del Rio contained lead vanadate; and he showed that the metal which Del Rio had called erythronium, and had then supposed to be impure chromium, was really vanadium. In 1831 Berzelius supposed he had prepared vanadium by heating an oxychloride in NH_3 , and also by heating the highest oxide with K (*P.* 22, 1); but in 1867 Roscoe (*T.* 1868, 1; 1869, 679; *v.* also 1870, 317) showed that one of the substances which until then had been taken to be the element V was a nitride, and that another substance, taken to be V, was an oxide of this element. Roscoe obtained pure V by heating $VOCl_2$ to redness for many hours in dry H. Roscoe was led to doubt the accuracy of the statement of the properties and at. w. of V that had been accepted on the authority of Berzelius, because he found that several compounds of V and Pb were isomorphous, but that it was impossible to assign comparable formulæ to these compounds if the at. w. given by Berzelius for V were accepted (*v. T.* 1868, 1 *et seq.*). Berzelius gave the value 68.5 to the at. w. of V; he assigned the formulæ VO , VO_2 , and VO_3 ($O=8$) to the three oxides, and classed V with Cr, Mo, and W. Roscoe's researches showed that the at. w. of the metal is 51.2, that the oxides are best represented as V_2O_3 , V_2O_5 , and V_2O_6 , that the substance thought to be V was

really chiefly V_2O_5 , that the compound supposed by Berzelius to be $VOCl_2$ was $VOCl_3$, and that V must be classed with P and As.

Occurrence.—Small quantities of compounds of V are found fairly widely distributed; the element does not occur uncombined. The chief minerals that contain V compounds are *mottramite* (Cu-Pb vanadate), *descloizite* (Pb-Zn vanadate), *dechenite* (Pb-Zn-Cu vanadate), *roscoelite* (Al vanadate with K silicate), *vanadinite* (vanadate of lead with lead chloride), and some other minerals, which generally contain vanadates of Cu, Pb, Zn, or Ca. Small quantities of compounds of V are found in all *pisolitic limonites* (Böttger, *C. G.* 1878, 514), in some *pitchblendes*, *clays*, and *basalts*, and in a few other rocks. Compounds of V have also been found, in small quantities, in the slag from copper extraction works (Karsten, *P.* 52, 629; Witz a. Osmond, *Bl.* [2] 38, 49); in many specimens of pig-iron (*v.* Riley, *C. J.* 17, 21; cf. Hodges, *C. N.* 26, 238; Walz, *Am. Ch.* 6, 453); in some meteorites (*v.* Apjohn, *C. J.* 27, 104); in caustic soda and sodium phosphate (Schöne a. Rammelsberg, *B. B.* 1864, 681; Donath, *D. P. J.* 240, 318); and, according to Lookyer (*Pr.* 27, 279), probably in the sun.

Preparation.—1. From the refinery slag of the Taberg iron-ore. The finely-powdered slag is heated with KNO_3 and Na_2CO_3 , the fused substance is digested with boiling water, and solution of a salt of Ba or Pb is added to the filtered liquid; the ppd. Ba or Pb vanadate is decomposed by boiling with a slight excess of H_2SO_4 , and the solution is filtered from $BaSO_4$ or $PbSO_4$; the filtrate is neutralised by NH_3Aq and concentrated, and pieces of NH_4Cl are placed in the liquid until some NH_4Cl remains undissolved; the NH_4VO_3 , which is thus ppd. as a white crystalline powder is washed with conc. NH_4ClAq , and then with alcohol, and is then decomposed by heating strongly in an open vessel, whereby V_2O_5 is produced (Berzelius, *P.* 22, 1). Wöhler (*A.* 78, 125) employed a very similar process for preparing V_2O_5 from *limonite*.—2. From *vanadinite*. L'Hôte (*C. R.* 101, 1151) recommends to mix finely-powdered *vanadinite* (approximately $3Pb_3V_2O_8.PbCl_2$) with four times its weight of lampblack and a little oil, to heat strongly in a closed vessel, and then to heat to 300° in a stream of dry Cl, whereby $VOCl_3$ is formed, and distilled over into a cooled U-tube; other compounds of V are readily prepared from $VOCl_3$.—3. From the cobalt-ore of Mottram in Cheshire. This source of V compounds was discovered by Roscoe (*v. C. J.* [2] 6, 326). The Cheshire Keuper sandstone contains carbonates of Cu, carbonate of Pb and *galena*, *black cobalt-ochre*, iron oxides, and salts of As, Ag, Mn, and Ba. The compound of V was probably *vanadinite*. The sandstone was crushed, and the metallic compounds were dissolved by $HClAq$; bleaching-powder and milk of lime were added till the reaction was alkaline; and it was from the pp. thus obtained that Roscoe prepared V and its compounds. The lime pp. contained chiefly As, Cu, Fe, Pb, V, and Ca in combination with SO_4 and PO_4 ; it was heated in a furnace with ground coal to remove As, then roasted with a quarter its weight of Na_2CO_3 ,

and lixiviated with water; the solution was saturated with H_2S and filtered, and H_2S was boiled off; crude oxide of V was then pptd. by NH_4Aq ; the oxide was dried and heated with conc. HNO_3Aq to oxidise it to vanadic acid, which was then boiled with saturated $(\text{NH}_4)_2\text{CO}_3\text{Aq}$, and the somewhat soluble NH_4 vanadate was crystallised from water, and then strongly heated in an open vessel; the V_2O_5 thus obtained was suspended in water into which NH_3 was passed; the solution of NH_4 vanadate was filtered from silica, phosphates, &c., evaporated to dryness, and heated in an open vessel until V_2O_5 remained.

The metal vanadium is prepared by reducing VCl_3 in H (for preparation of VCl_3 v. VANADIUM DICHLORIDE, p. 844). The process is conducted in perfectly pure and dry H; every trace of moisture and air must be excluded. The pure and dry H is passed for 12 hours through a porcelain tube, connected (by specially arranged paraffin-joints) by a glass tube to the H apparatus; the VCl_3 is then placed in the porcelain tube (a special arrangement for doing this is described by Roscoe), and H is passed through the apparatus for 6 hours. The porcelain tube is then gradually heated to full redness, and the passage of H is continued so long as HCl is given off, after which the tube is allowed to cool for several hours in the stream of H. The process occupies from 40 to 80 hours according as from 1 to 4 g. of VCl_3 are used. The V thus obtained contains traces of H and O. Reduction proceeds more quickly at a white heat, but the product is not so pure; it generally contains c. 95 to 96 p.c. V. (For details, and figures of the apparatus, v. Roscoe, *T.* 1869. 679; 1870. 317; or *C. J.* [2] 8, 344; 9, 23.)

Moissan (*C. R.* 116, 1225) obtained V containing from 17.5 to 25.7 p.c. C, by heating a mixture of C and one of the oxides of V in an electric furnace, using a current of 70 volts and 1,000 ampères; with a current of 70 volts and 350 ampères reduction proceeded very slowly.

Vanadium, mixed with V_2O_5 , was obtained by Roscoe (*l.c.*) by strongly heating a mixture of one of the chlorides of V with Na in an atmosphere of H, and lixiviating with water; the admixed black, powdery V_2O_5 can be removed from the heavier, grey, lustrous, metallic powder, by repeated washings with water, and a substance containing c. 91 p.c. V can be obtained.

The substance supposed by Berzelius (*P.* 22, 1) to be V, and obtained by heating V_2O_5 with K, was shown by Roscoe to consist chiefly of V_2O_5 . The black powder which Uhrlaub (*P.* 103, 134) prepared by heating V oxychloride in NH_3 , and which he supposed to be V, was found by Schaffarik (*W. A. B.* 33, 5) to be VN_3 (*cf.* Roscoe, *l.c.*).

Properties.—A light-grey, lustrous powder; under the microscope it is seen to be composed of crystalline, silver-white particles. Does not become coherent and dense when strongly compressed. S.G. 5.5 at 15° . Not magnetic. Is not oxidised in air at the ordinary temperature, nor by moistening and then drying *in vacuo*. Has not been melted, except perhaps when reduced from the oxides by C in an electric furnace (v. Moissan, *C. R.* 116, 1225). When powdered V is thrown into a Bunsen flame it burns brilliantly; when strongly heated in O it forms

V_2O_5 ; and when slowly heated in air it perhaps forms V_2O_5 , then V_3O_5 , V_2O_4 , and finally V_2O_3 . Burns in Cl, forming VCl_3 ; combines with N to form VN; also combines with S. V is insoluble in HClAq ; it dissolves in hot conc. H_2SO_4 , and in HNO_3Aq . V dissolves in molten NaOH, giving off H, and for a time a vanadate. V acts on glass vessels in which it is heated, forming a compound with Si; it also alloys with Pt (*R.*, *l.c.*).

The at. w. of V has been determined (1) by reducing V_2O_5 to V_2O_3 by heating in H (Berzelius, *P.* 22, 15 [1831]; Roscoe, *T.* 1868. 8); (2) by oxidising V_2O_3 to V_2O_5 by HNO_3 (*B.*, *l.c.* [1831]); (3) by analysing $(\text{V}_2\text{O}_5)(\text{SO}_4) \cdot 4\text{H}_2\text{O}$ (*B.*, *l.c.*, p. 18 [1831]); (4) by ppg. VOCl_3 by AgNO_3Aq , removing excess of Ag from the filtrate, evaporating to dryness, heating, and weighing the V_2O_5 produced (*B.*, *l.c.* [1831]); (5) by determining the weight of Ag required to ppt. the Cl from VOCl_3 ; also by weighing the AgCl pptd.; also by filtering from AgCl, evaporating, and weighing the V_2O_5 obtained (Roscoe, *T.* 1868. 23); (6) by determining V.D.s of, and analysing, VCl_3 and VOCl_3 (*g. v.*). The results obtained by Berzelius (with the necessary corrections on account of the wrong formulæ used by him; v. Roscoe, *l.c.*) gave values for at. w. of V varying from 49.3 to 52.5; Roscoe's values from the reduction of V_2O_5 to V_2O_3 varied from 51.13 to 51.35, and from the analyses of VOCl_3 from 50.32 to 51.877. The S.H. of V has not been determined.

Vanadium is both metallic and non-metallic in its reactions. V_2O_5 interacts with strong acids to form divanadyl salts, $\text{V}_2\text{O}_5(\text{SO}_4)_2$, &c.; hypovanadates $\text{V}_2\text{O}_5(\text{OM})_2$ are also derived from a hydrate of V_2O_5 ; V_2O_5 interacts with conc. H_2SO_4 to form $\text{V}_2\text{O}_5 \cdot 3\text{SO}_3$ and $\text{V}_2\text{O}_5 \cdot 2\text{SO}_3 \cdot x\text{H}_2\text{O}$; V_2O_5 also forms $\text{V}_2\text{O}_5 \cdot \text{H}_2\text{O}$ ($=\text{HVO}_3$) and $\text{V}_2\text{O}_5 \cdot 2\text{H}_2\text{O}$ ($=\text{H}_2\text{V}_2\text{O}_7$), which react as acids, and salts of the acid H_2VO_4 are also known; V_2O_5 also combines with various acidic oxides (P_2O_5 , MoO_3 , &c.) and basic oxides, to form complex, salt-like compounds. The sulphides of V dissolve in alkali sulphide solutions; several thiovanadates have been isolated, e.g. $(\text{NH}_4)_2\text{VS}_4$; and also thio-oxyvanadates, e.g. $\text{Na}_2\text{VS}_2\text{O}$. The haloid compounds of V are generally decomposed by water to oxyhaloid compounds.

Vanadium is placed in Group V., with N, P, As, Nb, Sb, Bi, Er, Ta and Bi. V is the second member of the even series family of this group, the family consisting of N, V, Nb, Ta and an unknown element with an at. w. between those of Th (=232) and U (=239). Group V does not show a marked division into families; the gradation of properties from N to Bi is fairly regular, nevertheless the families (1) N and P, (2) V, Nb and Ta, (3) As, Sb and Bi are distinctly indicated. No hydrides of members of the vanadium family have been isolated with certainty. The highest oxides, M_2O_5 , are salt-forming; all of them interact with alkalis to form salts containing the elements M in the acidic radicles; V_2O_5 also forms basic salts $(\text{VO})_x\text{R}_y$, with strong acids; normal salts have not been obtained by the reactions of M_2O_5 with acids. Oxyacids of V, viz. HVO_3 and $\text{H}_2\text{V}_2\text{O}_7$, have been isolated, but definite oxyacids of Nb and Ta are unknown. Both Nb and Ta form chlorides, corresponding with their highest

oxides M_2O_5 ; but the highest haloid compound of V is VX_5 , corresponding with V_2O_5 ; oxyhaloid compounds of V of the form of VX_3 exist ($VOCl_3$, $VOBr_3$) (*v. NITROGEN GROUP OF ELEMENTS*, vol. iii. p. 571).

In considering the relations between vanadium and the elements of Group V., the position of V in series 4 must be taken into account: as compared with the elements that form series 3, in which series P is placed, the elements of the vanadium series are metallic (V is preceded by Ti, Sc, Ca and K, and is followed by Cr, Mn, and the iron elements); the elements of the vanadium series are nearly as metallic, and also as non-metallic, as Rb, Sr, Y, Nb, Mo, —, and the Ru metals, which elements form series 6, *i.e.* the niobium series. Hence V would be expected to be distinctly more like a metal, in its chemical relations, than P, and about equal to Nb in its metallic and non-metallic tendencies. As V is the second member of the even series family of Group V., it might be expected to resemble N, which is the first of the even series elements of this group; but it is to be remembered that the differences between the first and second even series members of the groups (*i.e.* the differences between Li and K, Be and Ca, B and Sc, C and Ti, N and V, O and Cr, F and Mn), become more marked in passing from Group I. to Group VII., and it is also to be remembered that the resemblances between the first even series members and the succeeding odd series members, become more marked as the atomic weights increase; F is more like Cl and Br than O is like S, Se, and Te; but O resembles S, Se, and Te more than N resembles P, As, Sb, &c.; and C is more like Si, Ge, Sn, &c., than B is like Al, Ga, In, &c.; but C less resembles Si, &c., than N resembles P, &c.

Reactions and Combinations.—(Roscoe, *T.* 1869. 679; 1870. 317.) 1. Heated in air, V burns to V_2O_5 ; lower oxides are first formed if the temperature is low.—2. Does not decompose water at 100° .—3. Heated to redness in chlorine burns to VCl_4 ; heated in bromine produces VBr_3 ; does not combine with iodine.—4. Heated with excess of sulphur, V forms V_2S_5 (*v. Kay, C. J.* 37, 728).—5. Heating in a stream of pure nitrogen produces VN.—6. V combines directly with silicon and also with platinum.—7. Molten potash or soda dissolves V, forming an alkali vanadate and giving off H.—8. V dissolves in conc. sulphuric acid (? forming a vanadyl salt); also in nitric acid, probably forming a basic nitrate; also, slowly, in hydrofluoric acid (? forming VF_3).

Detection and Estimation.—Small quantities of compounds of V give a colourless borax or microcosmic salt bead in the outer flame, becoming green in the reducing flame; if much V compound is present the bead is yellow in the outer flame. Solutions of V_2O_5 in acids are not pptd. by H_2S , but are reduced to solutions of V_2O_3 which are lavender-blue; if reduction is effected by Zn, Cd, or Na-amalgam the liquid becomes green, then blue, and finally lavender-blue; after reduction the solution bleaches indigo very rapidly, and soon absorbs O. Solutions of vanadates, either neutral or acidified by acetic acid, give finely-divided black pps. with tincture of galls, and the liquids appear like ink.

When an acidified solution of a vanadate is shaken with an ethereal solution of H_2O_2 , the latter solution becomes dark red (Werther, *J. pr.* 88, 195).

Vanadium is generally estimated by converting it into an ammonium salt, strongly heating this in air, and either weighing the V_2O_5 thus produced or heating in H and weighing the V_2O_3 that remains. For a volumetric method of estimating V *v. Gerlach (B.* 10, 1216).

Vanadium, acids of, *v.* VANADIUM OXYACIDS, AND SALTS AND DERIVATIVES THEREOF, p. 851.

Vanadium, bromides of. Only one bromide of V has been obtained.

VANADIUM TRIBROMIDE VBr_3 . Mol. w. not known; from analogy of PBr_3 , $AsBr_3$, &c., the formula VBr_3 is probably molecular. Formed by heating V or VN to redness in vapour of Br. Also by passing Br vapour over a mixture of V_2O_3 and C kept at a red heat; $VOBr_3$ is formed, then $VOBr_2$, and then VBr_3 sublimes (Roscoe, *T.* 1870. 317). Roscoe (*l.c.*) recommends to prepare VBr_3 by placing pure VN in a porcelain boat in a tube of hard glass, driving out all air by dry CO_2 , then passing vapour of Br through the tube while that part where the boat is placed is heated to redness, when brown vapours are given off and condense on the cooler parts of the tube, and finally driving out all traces of Br by a stream of dry CO_2 . VBr_3 is a greyish black, opaque, amorphous, very deliquescent solid; loses Br even in a sealed tube; heated gently in air gives V_2O_3 , and at a higher temperature V_2O_5 . Dissolves in water, without giving off any Br, forming a brown liquid which goes green on addition of a few drops of HCl aq; this reaction is said by R. to be characteristic of a salt of V_2O_3 .

Vanadium, chlorides of. Three chlorides have been isolated: VCl_2 , VCl_3 , and VCl_4 . V burns when heated in Cl, forming VCl_3 , and the other chlorides are formed by reducing VCl_3 by H. The V.D. of VCl_4 has been determined, and the formula VCl_4 is molecular; the formula VCl_3 is probably molecular, from the analogy of $AsCl_3$, PCl_3 , $BiCl_3$, &c.; VCl_2 , AsI_2 , PI_2 and $BiCl_2$ are the only haloid compounds of the form MX_2 that have been isolated in Group V.; the mol. w.s. of these compounds have not been determined.

VANADIUM TETRACHLORIDE VCl_4 . Mol. w. 192.68. Prepared by Roscoe (*T.* 1869. 691).

Formation.—1. V or VN is heated in Cl.—2. The vapour of $VOCl_3$, mixed with excess of Cl, is passed slowly over a long layer of sugar-charcoal heated to redness.

Preparation.—VN is heated to redness in a tube of hard glass, in a current of pure, dry Cl, which must be free from air. The first few drops of distillate are rejected, as they contain traces of $VOCl_3$ formed from traces of oxide in the nitride used. The dark-red liquid that is formed is saturated with dry Cl, then heated for some hours in a current of dry CO_2 in a vessel connected with an upright condenser, and then fractionated.

Properties and Reactions.—A thick, dark, brownish-red liquid; boils at 154° under 760 mm. pressure. S.G. 1.8584 at 0° , 1.8363 at 8° , 1.8159 at 30° . V.D. 98.1 at c. 200° . Does not solidify at any temperature above -18° . Slowly decomposes to VCl_2 and Cl at ordinary tempera-

tures, more quickly when exposed to light, and rapidly when heated. Gives off white fumes in the air. Dissolves in water, forming a blue solution, which does not bleach; this solution is oxidised by KMnO_4 to HClO_4 and V_2O_5 , taking up O. Reacts violently with alcohol and ether, forming deep-coloured liquids. When heated with Br in a sealed tube, VCl_3 is formed. VCl_3 does not combine with Cl to form a higher chloride. H_2S reacts with VCl_3 to form VCl_2 , HCl , and S (Kay, *C. J.* 38, 736).

VANADIUM TRICHLORIDE VCl_3 . Mol. w. not determined, but formula is probably molecular from analogy of PCl_3 , AsCl_3 , &c. Prepared by heating VCl_3 in a retort as long as Cl is given off, and heating the residual solid to 160° in a stream of dry CO_2 (Roscoe, *T.* 1869, 691). Also by heating pure V_2S_5 in a stream of dry, air-free Cl, separating S_2Cl_2 by repeatedly distilling the liquid product, and heating the residue at 140° in dry CO_2 to remove the last traces of S_2Cl_2 (Halberstadt, *B.* 15, 1619). Lustrous, peach-blossom coloured tablets, resembling CrCl_3 ; S.G. 3.0 at 18° . Deliquesces very rapidly in air to a brown liquid, which goes green on addition of a drop or two of HClO_4 ; this solution is oxidised by KMnO_4 , 2VCl_3 taking up 2O, to HClO_4 and V_2O_5 . Soluble in alcohol and in ether. Heated in air forms V_2O_5 . Heated in H is reduced to VCl_2 and then, gradually, to V.

VANADIUM DICHLORIDE VCl_2 . Mol. w. not known. Formula possibly V_2Cl_4 . Prepared by passing vapour of VCl_3 , mixed with a large excess of pure, dry H, through a glass tube heated to dull redness. The distillation of VCl_3 should be slow, and the mixture of vapour of VCl_3 and H should be brought at once into the heated part of the tube. Forms apple-green, micaceous, hexagonal plates; S.G. 3.23 at 18° ; very hygroscopic. Dissolves in water, forming a violet solution, which bleaches indigo and litmus, and reacts as a solution of a salt of V_2O_5 . Dissolves in alcohol and in ether. The solution in water is oxidised by KMnO_4 to HClO_4 and V_2O_5 , 2VCl_2 taking up 3O. Heated in H, is slowly reduced to V; heating to whiteness in NH_3 produces VN (Roscoe, *l.c.*).

Vanadium, ferrocyanide of, v. vol. ii. p. 337.

Vanadium, fluorides of. Only one fluoride, VF_5 , has been isolated; there are indications of the existence of a higher fluoride in solutions in conc. HFAq .

VANADIUM TRIFLUORIDE $\text{VF}_3 \cdot 3\text{H}_2\text{O}$. Mol. w. not known; formula probably molecular, from analogy of trihalides of other elements of Group V. Prepared by evaporating a solution of V_2O_5 in HFAq at 100° , and crystallising from water containing a little HFAq . A white crystalline crust, consisting of rhombohedra. Easily soluble in water; solution reacts acid. Insoluble in conc. alcohol. Effloresces in air; loses some water at 100° , and all at 130° , with absorption of O; V_2O_5 is formed on heating to redness in air. An aqueous solution reduces Ag salts to Ag, Hg and Cu salts to mercurous and cuprous salts; alkalis or alkali carbonates ppt. $\text{V}_2\text{O}_5 \cdot x\text{H}_2\text{O}$ from VF_3 (E. Petersen, *J. pr.* [2] 40, 44).

Vanadoxyfluorides. (Fluovanadates.) A number of compounds of the forms $\text{VF}_5 \cdot x\text{MF}$ and $\text{VF}_5 \cdot x\text{MF}_2$ were obtained by Petersen (*l.c.*) by adding various fluorides to solutions of V_2O_5

in HFAq , and crystallising. These salts are generally greenish coloured, and crystalline; most of them are soluble in water, but not in KFAq ; they lose water of crystallisation from 100° to 200° . The vanadoxyfluorides may be regarded as salts of hypothetical acids HVF , H_2VF , and H_3VF ; they may also be formulated as double salts (*v. supra*). The following salts are described by Petersen (*l.c.*):

Ammonium vanadoxyfluorides $\text{NH}_4\text{VF}_5 \cdot 2\text{aq}$, $(\text{NH}_4)_2\text{VF}_6 \cdot \text{aq}$, and $(\text{NH}_4)_3\text{VF}_7$.

Cadmium vanadoxyfluoride $\text{CdVF}_5 \cdot 7\text{aq}$ (Piccini a. Giorgis, *G.* 22 [1] 55).

Cobalt vanadoxyfluoride $\text{CoVF}_5 \cdot 7\text{aq}$.

Nickel vanadoxyfluoride $\text{NiVF}_5 \cdot 7\text{aq}$.

Potassium vanadoxyfluoride $\text{K}_2\text{VF}_6 \cdot \text{aq}$.

Sodium vanadoxyfluoride $\text{Na}_2\text{V}_2\text{F}_{11} \cdot \text{aq}$ = $2\text{VF}_5 \cdot 5\text{NaF} \cdot \text{aq}$ (? $\text{Na}_2\text{VF}_6 \cdot \text{aq}$).

Zinc vanadoxyfluoride $\text{ZnVF}_5 \cdot 7\text{aq}$ (P. a. G., *l.c.*).

Vanadoxyfluorides. (Fluoxyvanadates.)

These salts are generally produced by dissolving V_2O_5 in HFAq , adding metallic fluorides, and crystallising; also by dissolving V_2O_5 in solutions of metallic fluorides, and crystallising; some of them are obtained by treating solutions of V_2O_5 in metallic fluoride solutions with reducing agents, and then crystallising. The vanadoxyfluorides have been examined by Baker (*C. J.* 33, 388 [1878]), Ditte (*C. R.* 105, 1067; 106, 270 [1888]), Piccini a. Giorgis (*G.* 18, 186 [1889]; *G.* 22 [1] 55 [1892]), and Petersen (*B.* 21, 3257 [1888]; more fully in *J. pr.* [2] 40, 193, 271 [1890]). There are still considerable discrepancies between the results obtained by the different observers. For a criticism of Baker's results *v. Petersen* (*J. pr.* [2] 40, 289-92). The vanadoxyfluorides belong to two main classes: (1) those obtained by dissolving V_2O_5 in HFAq , adding a fluoride (or carbonate), and crystallising: many of these salts are also formed by dissolving V_2O_5 in solutions of fluorides, and crystallising; (2) those obtained by partially reducing solutions of V_2O_5 in HFAq , then adding fluorides, and crystallising. The first class of salts may be divided into (i.) those wherein one atom of O in V_2O_5 is substituted by 2F, and which, therefore, are represented as $x\text{MF} \cdot y\text{VO}_2\text{F}$ (V_2O_5 gives $\text{V}_2\text{O}_5\text{F}_2 = 2\text{VO}_2\text{F}$); and (ii.) those wherein 3O in V_2O_5 is substituted by 6F, and which, therefore, are represented as $x\text{MF} \cdot y\text{VOF}$, (V_2O_5 gives $\text{V}_2\text{O}_5\text{F}_6 = 2\text{VOF}_3$). Salts of the second class are regarded as compounds of MF with VOF_2 , and VOF_2 is looked on as obtained by substituting 2O in V_2O_5 by 4F (V_2O_5 gives $\text{V}_2\text{O}_5\text{F}_4 = 2\text{VOF}_2$). The salts derived from V_2O_5 , *i.e.* $x\text{MF} \cdot y\text{VO}_2\text{F}$ and $x\text{MF} \cdot y\text{VOF}$, are often called *fluoxyvanadates*, and those derived from V_2O_4 , *i.e.* $x\text{MF} \cdot y\text{VOF}$, are often called *fluoxyhypovanadates*; the former class of salts will here be called *vanadoxyfluorides*, and the latter *hypovanadoxyfluorides*.

Ammonium vanadoxyfluorides. Three salts are described by Baker (*C. J.* 33, 388 [1878]), and also by Piccini a. Giorgis (*G.* 22 [1] 55, [1892]); the formulæ given by the different experimenters do not agree.

Lamellar ammonium vanadoxyfluoride. This salt was obtained by Baker by dissolving V_2O_5 in NH_4HFAq , and then adding more NH_4HF_2 ; it separates in small yellow, pearly,

hexagonal plates. P. a. G. obtained the salt by dissolving V_2O_5 in a slight excess of HFAq, adding NH_4F in the ratio $3NH_4F:2V_2O_5$, and evaporating. B. gives the formula $6NH_4F.V_2O_5.2VOF_2$; P. a. G. give the formula $3NH_4F.2VOF_2$. If both formulæ are expressed as $3NH_4F.2VOF_2$, then $x=1\frac{1}{2}$ in Baker's formula and $=2$ in the formula of P. a. G. A salt obtained by Petersen (*J. pr.* [2] 40, 193, 271 [1890]), by a similar process to those used by B. and by P. a. G., was formulated by him as $7NH_4F.4VOF_2.HF$.

Pyramidal ammonium vanadoxyfluoride. Obtained by Baker by adding NH_4HF_2 to a solution of the lamellar salt; P. a. G. prepared the salt by dissolving V_2O_5 in excess of HFAq, and exactly neutralising the hot solution by NH_4Aq . This salt crystallises in yellow, simple pyramids (Baker). The formula assigned by B. is $12NH_4F.V_2O_5.2VCO_2$, while that given by P. a. G. is $3NH_4F.VO_2F$; Petersen gives the same formula as P. a. G. If Baker's formula is expressed as $3NH_4F.VO_2F_v$, x must be put $=1\frac{1}{2}$, and $y=1\frac{1}{2}$.

Acicular ammonium vanadoxyfluoride. Baker obtained this salt by dissolving the pyramidal salt in warm HFAq and allowing to cool; P. a. G. prepared it by a similar reaction. This salt crystallises in pale-yellow acicular prisms; when dry it has the odour of HF; it acts on glass. The formula given by P. a. G. is $3NH_4F.2VOF_2$; Baker assigned to this salt the formula $3NH_4HF_2.2VOF_2$, but his analyses were, admittedly, not very trustworthy.

Adopting the formulæ given by P. a. G. for the three ammonium vanadoxyfluorides, these salts are represented as

- (1) $3NH_4F.2VOF_2 = (NH_4)_3V_2O_5F_8$
- (2) $3NH_4F.VO_2F = (NH_4)_3VO_2F_4$
- (3) $3NH_4F.2VOF_2 = (NH_4)_3V_2O_5F_8$.

A few of the other vanadoxyfluorides seem to belong to one or other of these types; P. a. G. and also Petersen, describe a *potassium vanadoxyfluoride* $3KF.2VOF_2 = K_3V_2O_5F_8$, belonging to the same form as the lamellar ammonium salt. But most of the vanadoxyfluorides described belong to forms which are not represented by the ammonium salts. The following are the principal salts:—

Ammonium salts. $9NH_4F.5VOF_2.3HF$; $7NH_4F.4VOF_2.HF$ (Petersen).

Potassium salts $2KF.VO_2F$; $2KF.VOF_2$; $3KF.2VOF_2.HF$; $4KF.VF_3.VOF_2$ (P.).

Sodium salt $3NaF.VOF_2.VO_2F$ (P. a. G.).

Zinc salts. $ZnF_2.VO_2F.7aq$ (P. a. G.); $ZnF_2.ZnO.2VOF_2.14aq$ (B.).

In none of these compounds does the atomic ratio of V to O exceed 1:2. According to Ditte (*C. R.* 105, 1067; 106, 270 [1888]), many compounds of alkali fluorides with V_2O_5 are formed by heating the constituents together, digesting with water, and crystallising; the atomic ratio of V to O in these compounds, as given by Ditte, is 2:5. The formulæ assigned to the compounds may be generalised as $xV_2O_5.yMF$; $M=K$ or Na , $x=1, 8$, and 4, and $y=1, 2, 4$, and 8. Ditte (*l.c.*) says that crystals of $V_2O_5.4NH_4F.4aq$ are obtained by dissolving V_2O_5 in hot conc. NH_4FAq , and that this compound is formed, along with $V_2O_5.8NH_4F.4aq$, when V_2O_5 is dissolved in cold

conc. NH_4FAq ; but the experiments of Baker, Piccini a. Giorgis, and Petersen, all agree in assigning to the compounds formed in these reactions formulæ wherein the atomic ratio of V to O does not exceed 1:2.

Hypovanadoxyfluorides. (*Fluoxhypovanadates.*) These compounds are formed by partially reducing mixtures of V_2O_5 and fluorides, or carbonates, dissolved in HFAq. If sufficient F is assigned to the metal present to form the normal fluoride, then the atomic ratio of V to the remaining F in these compounds is 1:2, and that of V to O is 1:1; the formulæ are written $xMF.yVOF_2$. All the salts described by Baker and Piccini a. Giorgis, except one, belong to the form $2M^+F.VOF_2$ or $M^{II}F_2.VOF_2$; these formulæ may evidently be written M^+_2 (or M^{II}) VOF_2 .

Ammonium hypovanadoxyfluoride $2NH_4F.VOF_2$. $aq (= (NH_4)_2VOF_2.aq)$ was prepared by Baker (*C. J.* 33, 395) by passing H_2S into a solution of V_2O_5 in HFAq, concentrating, filtering, and adding NH_4F . The same salt was prepared by Piccini a. Giorgis (*G.* 22 [1] 55) by electrolytically reducing a solution of NH_4VO_3 in HFAq, after adding NH_4F ; also by reducing NH_4VO_3 in HFAq by SO_2Aq , neutralising by NH_4Aq , and adding NH_4F ; and in each case dissolving the crystals that were formed (said by P. a. G. to be $3NH_4F.VOF_2$) in hot HFAq, and crystallising. Petersen (*J. pr.* [2] 40, 196) also obtained this salt. The salt crystallises in clear blue monoclinic forms; $a:b=9653:1$ (Baker, *l.c.*).

Petersen (*J. pr.* [2] 40, 197) described two other ammonium hypovanadoxyfluorides, $7NH_4F.4VOF_2.5aq$ and $3NH_4F.VOF_2$.

The other hypovanadoxyfluorides described by P. a. G. (*l.c.*) are $2KF.VOF_2$ and $MF_2.VOF_2.2aq$ where $M=Cd, Co, Ni$ and Zn . The K salt was prepared by reducing V_2O_5 in HFAq by SO_2Aq and adding KF; the other salts by dissolving MO , or MCO_3 , along with V_2O_5 in HFAq, and reducing electrolytically. According to Petersen (*l.c.* pp. 199, 200), the salts $7KF.3VOF_2$ and $8NaF.3VOF_2.2aq$ also exist.

P. a. G. (*l.c.*) remark that the tendency to form highly fluorinated compounds increases in the family V, Nb, Ta as the atomic weight increases; thus, VO_2F is not affected by a little HFAq, while Nb_2OF_6 forms $NbOF_3$, and $TaOF_5$ is converted into TaF_5 . They also point out that the three compounds, $ZnF_2.VO_2F.7aq$, $ZnF_2.VOF_2.7aq$, and $ZnF_2.VF_3.7aq$, all crystallise with the same number of molecules of water, all contain the same number of atoms, have the same crystalline form, and are geometrically isomorphous.

VANADIUM PENTAFLUORIDE VF_5 . According to Petersen (*J. pr.* [2] 40, 271), this compound exists in a solution of V_2O_5 in conc. HFAq. No compound was isolated, nor is any trustworthy evidence given of the existence of VF_5 in solution.

Vanadium, haloid compounds of. When V is heated in excess of Cl the tetrachloride VCl_4 is produced; heating in Br produces the tribromide VBr_3 . V does not combine with I. The haloid compounds of V belong to the forms VX_4 , VX_3 , and VX_2 ; $X=Cl$ in each case, $X=Br$ or F in the one case of VX_3 . The formula VX_4 is molecular; the other formulæ are probably molecular. VCl_3 , $BiCl_3$, AsI_3 , and PI_3 are the

only dihalides known of members of Group V. Attempts to prepare halides higher than VX_3 have failed. Solutions in water of the haloid compounds of V behave like solutions of the corresponding oxides in haloid acids; VCl_3 Aq like a solution of V_2O_5 in HCl Aq, VX_3 Aq like a solution of V_2O_5 in $HXAq$, and VCl_2 Aq like a solution of V_2O_3 in HCl Aq. VCl_3 is decomposed by heat to VCl_2 and Cl_2 , and heating VCl_3 with H produces VCl_2 . VF_3 combines with metallic fluorides to form *vanadofluorides*, many of which belong to the form M_2VF_6 or $M^+VF_6^-$ (v. p. 844). Several oxychlorides and oxybromides of V have been isolated: VOX_2 and VOX_3 , where $X = Cl$ or Br ; also $VOCl$, V_2O_3Cl , and VO_2Cl ; the existence of other oxybromides also is probable. No oxyfluoride has been isolated with certainty. But many compounds exist which may be regarded as containing the oxyfluorides VO_2F , VOF_2 , and VOF_3 , respectively; the compounds $VO_2F \cdot xMF$ and $VOF_2 \cdot xMF$ are obtained by dissolving V_2O_5 and fluorides in $HFAq$ and crystallising; they are described as *vanadoxyfluorides* (p. 844); the compounds $VOF_2 \cdot xMF$ are obtained by partially reducing solutions of V_2O_5 and fluorides in $HFAq$, they are described as *hypovanadoxyfluorides* (p. 845).

Vanadium, iodides of. No iodide of V has been isolated. No reaction occurs when vapour of I is passed over VN heated to redness, nor do I and V_2O_5 react at any temperature (Roscoe, *C. J.* [2] 9, 28). I does not react with V_2O_5 when digested therewith for a long time in presence of water or alcohol (Guyard, *Bl.* [2] 25, 351).

Vanadium, nitrides of. V and N combine directly. Two nitrides are known.

VANADIUM MONONITRIDE VN. Mol. w. not known. Obtained by heating V in a stream of pure N; also by saturating $VOCl_3$ with dry NH_3 , and heating to full whiteness in a stream of NH_3 . Better prepared by heating NH_4VO_3 in the air, and then heating the residue to a full white heat in a stream of dry NH_3 (Roscoe, *C. J.* [2] 8, 844). VN may also be prepared by heating V_2O_5 to whiteness in NH_3 (R., *l.c.*). VN is a greyish-brown, metal-like powder; heated in air it is oxidised to V_2O_3 , and then to V_2O_5 ; heated with soda-lime it gives off NH_3 .

VANADIUM DINITRIDE VN_2 . A black powder; exposed to air gives off NH_3 and is oxidised. Prepared by saturating $VOCl_3$ with dry NH_3 , heating the solid so obtained in a glass tube as long as NH_4Cl sublimes, washing the residue with water containing a little NH_3 , and drying *in vacuo* over H_2SO_4 (Roscoe, *C. J.* [2] 6, 849); examined by Uhrlaub, who did not succeed in determining its composition (P. 108, 184; cf. Schafarik, *W. A. B.* 33, 5).

Vanadium, oxides and hydrated oxides of. By gently heating V in air the oxide V_2O_3 is possibly formed, and, on continued heating, oxidation proceeds to V_2O_3 , V_2O_4 , V_2O_5 , and finally V_2O_5 . The oxides V_2O_3 , V_2O_4 , and V_2O_5 are also formed by reducing V_2O_5 by heating with H or K. Several oxides intermediate between V_2O_3 and V_2O_5 seem also to exist. The oxides V_2O_3 , V_2O_4 , V_2O_5 , and V_2O_5 are feebly basic; V_2O_3 and V_2O_4 are also acidic. The oxides of V correspond in composition with the oxides of N; corresponding oxides of Bi

are known. The names generally given to the oxides of V do not, unfortunately, tally with the names given to the corresponding oxides of N; thus, V_2O_3 is generally called hypovanadous oxide, while NO is called nitric oxide; V_2O_5 is called vanadic oxide, while the name nitrogen peroxide is often quite wrongly applied to NO_2 . The mol. w. of none of the oxides of V is known.

? **VANADIUM MONOXIDE (V_2O).** 'When the powdered metal is . . . slowly heated in a current of air it glows brightly, with absorption of oxygen, forming in the first place a brown oxide (V_2O or V_2O_3); and on further heating this oxide again glows, and passes through the black trioxide and blue tetroxide to pentoxide' (Roscoe, *C. J.* [2] 8, 357). This statement seems to contain all that is known of an oxide lower than V_2O_3 .

VANADIUM DIOXIDE V_2O_4 (*Hypovanadous oxide*). This substance was supposed by Berzelius (P. 22, 1) to be V; Roscoe (T. 1868. 1) proved it to be an oxide with the atomic ratio $V:O = 1:1$. The mol. w. is not known; the formula is generally written V_2O_4 rather than VO , as the double formula is, on the whole, more in keeping with the reactions of the compound.

Formation.—1. By heating one of the higher oxides with K (Berzelius, *l.c.*).—2. By passing vapour of $VOCl_3$, mixed with much dry H, over red-hot charcoal (Schafarik, A. 109, 85).—3. By strongly heating V_2O_3 and V_2O_5 , mixed in the ratio $V_2O_3:V_2O_5$, out of contact with air (Petersen, *J. pr.* [2] 40, 193).

Preparation.—A mixture of much dry H and vapour of $VOCl_3$ (q. v. p. 854) is passed through a hard glass tube containing powdered charcoal and kept red hot. Some solid oxychlorides are deposited on the cooler parts of the tube, while the V_2O_4 remains mixed with the C. The contents of the tube are then strongly heated in a current of dry H to remove traces of Cl compounds; and the grey metal-like V_2O_4 is separated from the C (Roscoe, *C. J.* [2] 6, 834). When Zn, Cd, or Na-amalgam is added to a solution of V_2O_4 in H_2SO_4 Aq (prepared by dissolving the oxide in hot conc. acid and diluting with 50 pts. water), the liquid becomes blue, green, and finally lavender. The lavender solution absorbs O very rapidly; exposure to the air for a few seconds causes the colour to change to deep chocolate-brown. By determining the quantity of standardised $KMnO_4$ decolourised by the lavender solution, Roscoe (*C. J.* [2] 6, 834) proved that this solution contained V_2O_4 , probably combined with SO_4 . After passing air into the lavender solution until it becomes permanently blue, the solution contains V_2O_5 ; if the free acid in the lavender solution is neutralised by zinc, and the liquid is then exposed to the air until permanently brown, and a little acid is then added, a green solution is formed which contains V_2O_4 (R., *l.c.*).

Properties and Reactions.—A light-grey, lustrous powder; or a lustrous, metal-like, crystalline crust, S.G. 3.64; very brittle; fuses at a very high temperature. Heated to redness in air, V_2O_4 burns to V_2O_5 ; heated in O, burns to V_2O_5 . Insoluble in water; dissolves in dilute acids, giving a lavender solution, which bleaches strongly; from these solutions KOH Aq or

NH_3Aq ppts. a brown hydrated oxide, which rapidly oxidises (Brierley, *C. J.* 49, 824). According to Petersen (*J. pr.* [2] 40, 194), V_2O_5 dissolves in HFAq , and on evaporation, solution of the residue in water, and evaporation over H_2SO_4 , blue, microscopic crystals are obtained, which are, perhaps, $\text{VOF}_2 \cdot x\text{aq}$; no analyses were made. Addition of alkali fluorides to V_2O_5 in HFAq produces various compounds of the form $x\text{VOF}_2 \cdot y\text{MF}$ (*v. HYPOVANADOXYFLUORIDES*, p. 845).

HYDRATE OF VANADIUM DIOXIDE. By adding NH_3Aq to a lavender-coloured solution of V_2O_5 (? in $\text{H}_2\text{SO}_4\text{Aq}$), Brierley (*C. J.* 49, 824) obtained a deep-purple gelatinous pp. which he said was hydrated V_2O_5 ; the pp. rapidly oxidised in the air.

VANADIUM TRIOXIDE V_2O_5 . (*Vanadous oxide. Vanadium sesquioxide.*) Mol. w. not known. This compound was represented by Berzelius as VO ($\text{V} = 68.5$, $\text{O} = 8$).

Formation.—1. By heating V_2O_5 to redness in H (Schäffarik, *A.* 109, 85). The presence of traces of P_2O_5 prevents reduction (Roscoe, *C. J.* [2] 6, 331).—2. By heating V_2O_5 in a carbon crucible (Berzelius, *P.* 22, 1).

Preparation.—Pure V_2O_5 is heated in perfectly pure and dry H until the substance ceases to lose weight; the tube is allowed to cool completely in H , and then a stream of dry air is passed through it (Roscoe, *C. J.* [2] 6, 331). When a solution of V_2O_5 in conc. H_2SO_4 is much diluted, and then treated with Mg until the liquid is green, this solution contains V_2O_5 , combined with SO_3 (*v. VANADOUS SALTS, infra*). A similar solution is obtained from the lavender solution of V_2O_5 in $\text{H}_2\text{SO}_4\text{Aq}$ (prepared from V_2O_5 in H_2SO_4 , *v. supra*) by neutralising free acid by zinc, exposing to the air, and adding a little acid (Roscoe, *C. J.* [2] 6, 337).

Properties and Reactions.— V_2O_5 is a black powder, resembling graphite; or, formed by reducing VOCl_3 by H , it is a black, lustrous, crystalline crust. S.G. 4.72 at 16° . Does not fuse in the blowpipe flame. When warm V_2O_5 is exposed to the air it glows and oxidises to V_2O_5 ; and even at the ordinary temperature it takes up O , being changed after some months to V_2O_5 (R., *l.c.*). Heated in Cl gives V_2O_5 and VOCl_3 (R., *l.c.*). Heated in NO_2 to $300^\circ\text{--}400^\circ$ V_2O_5 is oxidised to V_2O_5 (Sabatier & Senderens, *C. R.* 115, 236). Heating to redness in H_2S produces V_2S_5 (Kay, *C. J.* 37, 728). V_2O_5 dissolves in hot conc. H_2SO_4 , forming $\text{V}_2\text{O}_5 \cdot x\text{SO}_3$ (*v. VANADOUS SALTS, infra*). V_2O_5 dissolves in HFAq , and $\text{VF}_3 \cdot 3\text{H}_2\text{O}$ has been isolated from this solution (*v. VANADIUM TRIFLUORIDE*, p. 844).

HYDRATE OF VANADIUM TRIOXIDE. By adding KOHAc , or NH_3Aq , to an aqueous solution of $\text{V}_2\text{O}_5 \cdot 4\text{SO}_3 \cdot 9\text{H}_2\text{O}$ (*v. infra*) Brierley (*C. J.* 49, 824), obtained a dirty green, gelatinous pp., which oxidised rapidly in air. According to B., this pp. was hydrated V_2O_5 .

VANADOUS SALTS $\text{V}_2\text{O}_5 \cdot x\text{X}$ ($\text{X} = \text{acidic oxide}$ or V_2R_3 , ($\text{R} = \text{acidic radicle}$)). Only one salt derived from an oxyacid has been certainly isolated; it has the composition $\text{V}_2\text{O}_5 \cdot 4\text{SO}_3 \cdot x\text{H}_2\text{O}$, or the formula may be written $\text{V}_2\text{H}_2(\text{SO}_4)_x \cdot y\text{H}_2\text{O}$.

Vanadous tetrakisulphate, or acid vanadous sulphate, $\text{V}_2\text{O}_5 \cdot 4\text{SO}_3 \cdot x\text{H}_2\text{O}$ or $\text{V}_2\text{H}_2(\text{SO}_4)_4 \cdot y\text{H}_2\text{O}$.

A hydrate with $x = 3$ or $y = 2$ was obtained

by Gerland (*B.* 10, 2111 [1877]) by heating a solution of V_2O_5 in a large excess of conc. H_2SO_4 for a long time at 120° , and treating the blue crystalline crust thus formed (consisting chiefly of $\text{V}_2\text{O}_5 \cdot 3\text{SO}_3 \cdot x\text{aq}$, *v. HYPOVANADIC SALTS*, p. 848) with boiling water, when $\text{V}_2\text{O}_5 \cdot 4\text{SO}_3 \cdot 3\text{H}_2\text{O}$ remained. G. supposed that reduction of V_2O_5 was effected by dust in the air.

Brierley (*C. J.* 49, 822 [1886]) prepared $\text{V}_2\text{O}_5 \cdot 4\text{SO}_3 \cdot 9\text{H}_2\text{O}$ ($= \text{V}_2\text{H}_2(\text{SO}_4)_4 \cdot 8\text{H}_2\text{O}$) by electrolysis a solution of V_2O_5 in H_2SO_4 . The solution was prepared by reducing V_2O_5 in conc. H_2SO_4 , after dilution, by SO_2 . The deep-blue solution was placed in a Pt dish which formed the negative electrode, and a porous pot containing dilute $\text{H}_2\text{SO}_4\text{Aq}$ was arranged so that it just touched the surface of the liquid in the Pt dish; a plate of Pt immersed in the $\text{H}_2\text{SO}_4\text{Aq}$ formed the positive electrode. The Pt dish was warmed during the process, so that electrolysis and evaporation proceeded together. Electrolysis was continued until the liquid was deep green, and a drop placed in a little water showed no trace of blue colour. Conc. H_2SO_4 , equal to twice the bulk of the green liquid, was added; after 24 hours the green, sandy pp. was collected, washed with conc. alcohol, and dried over H_2SO_4 in coal-gas. The salt dissolved in water, and alkali ppd. from this solution a dirty-green gelatinous substance, said by B. to be $\text{V}_2\text{O}_5 \cdot x\text{H}_2\text{O}$. This pp. dissolved in an aqueous solution of $\text{V}_2\text{O}_5 \cdot 4\text{SO}_3 \cdot 9\text{H}_2\text{O}$, forming a chocolate-brown solution, giving a lustrous green solid on evaporation, which dissolved in water to form a brown solution. B. concluded that the brown solution contained a compound of V_2O_5 and SO_3 , more basic than $\text{V}_2\text{O}_5 \cdot 4\text{SO}_3$.

Gerland (*B.* 11, 106 [1878]) mentions the normal vanadous sulphate $\text{V}_2(\text{SO}_4)_3$ ($= \text{V}_2\text{O}_5 \cdot 3\text{SO}_3$) as if he had prepared it; no details are given.

VANADIUM TETROXIDE V_2O_4 . (*Hypovanadous oxide.*) Mol. w. not known. Represented by Berzelius as VO_2 ($\text{V} = 68.5$, $\text{O} = 8$).

Formation.—1. By allowing V_2O_5 to absorb O from the air (*cf. HYPOVANADO-VANADIC OXIDES*, p. 851).—2. By strongly heating a mixture of 5 pts. V_2O_5 and 6 pts. V_2O_3 , in absence of air.—3. By the electrolysis of molten V_2O_5 (Buff & Wöhler, *A.* 110, 277).—4. By heating $\text{V}_2\text{O}_5 \cdot \text{Cl}_2 \cdot 5\text{aq}$ in a stream of CO_2 (Crow, *C. J.* [2] 15, 453).

Preparation.—A solution of V_2O_5 in H_2SO_4 , obtained by reducing V_2O_5 in conc. H_2SO_4 by SO_2 , is ppd. by $\text{Na}_2\text{CO}_3\text{Aq}$, and the pp. is washed and dried by heating *in vacuo* (Berzelius, *P.* 22, 1).—2. V_2O_5 is exposed to the air for some months, until the colour has changed to blue (Roscoe, *C. J.* [2] 6, 338).—3. V_2O_5 is dissolved in hot conc. HClAq ; when Cl ceases to be given off the liquid is saturated with H_2S , filtered from S , evaporated to dryness at 100° and the $\text{V}_2\text{O}_5 \cdot \text{Cl}_2 \cdot x\text{aq}$ thus formed is heated to redness in a stream of dry CO_2 (Crow, *l.c.* pp. 457, 458).

Properties and Reactions.—A blue, lustrous, crystalline powder; prepared by heating $\text{V}_2\text{O}_5 \cdot \text{Cl}_2$ in CO_2 it forms a dark-green, amorphous powder (Crow, *l.c.*). Infusible at a high temperature. Insoluble in water. When kept in a loosely-stoppered bottle V_2O_4 gradually absorbs O , forming V_2O_5 (Crow, *l.c.*). Dissolves easily in acids, forming bright-blue liquids; the same solutions are obtained by the action of moderate

reducers, such as SO_2Aq , H_2SAq , or $\text{H}_2\text{C}_2\text{O}_4\text{Aq}$, on solutions of V_2O_5 in acids, also by passing air into V_2O_5 in $\text{H}_2\text{SO}_4\text{Aq}$ until the liquid becomes permanently blue (Roscoe, *l.c.*; *v. infra*, HYPOVANADIC SALTS). Petersen (*J. pr.* [2] 40, 194) supposed that the blue microscopic crystals he obtained by dissolving V_2O_5 in excess of HFAq and evaporating were $\text{VOF}_2 \cdot x\text{aq}$, but he did not obtain enough to make an analysis. V_2O_5 dissolves readily in alkali solutions, forming *hypovanadates*, $\text{M}_2\text{V}_2\text{O}_7$ (*q. v.* under VANADIUM OXYACIDS, AND SALTS AND DERIVATIVES THEREOF, p. 853).

HYDRATES OF HYPOVANADIC OXIDE. By adding $\text{Na}_2\text{CO}_3\text{Aq}$, drop by drop, to a solution of V_2O_5 in HClAq or $\text{H}_2\text{SO}_4\text{Aq}$, till the supernatant liquid was colourless, filtering rapidly in CO_2 , and drying on a porous tile over H_2SO_4 *in vacuo*, Crow (*l.c.*) obtained the black, amorphous *heptahydrate* $\text{V}_2\text{O}_5 \cdot 7\text{aq}$; and on heating this in CO_2 for some hours at 100° he obtained the *trihydrate* $\text{V}_2\text{O}_5 \cdot 3\text{aq}$.

HYPOVANADIC (or vanadyl) SALTS $\text{V}_2\text{O}_5 \cdot x\text{X}$ (X = acidic oxide). Only a few compounds of V_2O_5 with acidic oxides have been isolated. The sulphates have been studied more than any other salts; they are most simply represented as $\text{V}_2\text{O}_5 \cdot x\text{SO}_3 \cdot y\text{H}_2\text{O}$. The compound $\text{V}_2\text{O}_5 \cdot 2\text{SO}_3$ may be called the normal sulphate; the formula may be expressed as $\text{V}_2\text{O}_5 \cdot (\text{SO}_3)_2$ or $\text{VO} \cdot \text{SO}_3$. The compound $\text{V}_2\text{O}_5 \cdot 3\text{SO}_3 \cdot 6\text{H}_2\text{O}$ may be called acid sulphate; the formula may be expressed as $\text{V}_2\text{O}_5 \cdot \text{SO}_3 \cdot (\text{SO}_3\text{H})_2 \cdot 5\text{H}_2\text{O}$ or $(\text{V}_2\text{O}_5)_2\text{H}_2(\text{SO}_3)_2 \cdot 5\text{H}_2\text{O}$, or $(\text{VO} \cdot \text{SO}_3)_2 \cdot \text{H}_2\text{SO}_4 \cdot 5\text{H}_2\text{O}$, or it may be written $\text{V}_2\text{O}_5 \cdot 2\text{SO}_3 \cdot \text{H}_2\text{SO}_4 \cdot 5\text{H}_2\text{O}$. When the formulæ of the compounds of V_2O_5 with acidic oxides are written $\text{V}_2\text{O}_5 \cdot \text{X}$ the compounds are generally called *hypovanadic salts*; when the formulæ are written $\text{V}_2\text{O}_5 \cdot x\text{R}$ (R = acidic radicle) the name *divanadyl salts* is usually given to the compounds; and when these compounds are regarded as $\text{VO} \cdot x\text{R}$, it is customary to call them *vanadyl salts*. Hypovanadic sulphates are obtained (1) by dissolv-

H_2SO_4 and heating to the boiling-point of the liquid for a long time. The salt separated as a green-blue powder; insoluble in water, cold or hot; insoluble HClAq and H_2SO_4 . (G. does not say how the salt was obtained pure for analysis; no analyses are given of the salt prepared exactly as described above.) Various *hydrates* are described by G. obtained by different processes. Crow (*C. J.* [2] 15, 456 [1876]), obtained the *heptahydrate* by repeatedly treating hexahydrated trisulphate (*v. infra*) with absolute alcohol.

Hypovanadic trisulphate, or acid divanadyl sulphate, $\text{V}_2\text{O}_5 \cdot 3\text{SO}_3 \cdot x\text{H}_2\text{O}$ or $(\text{V}_2\text{O}_5)_2\text{H}_2(\text{SO}_3)_3 \cdot y\text{H}_2\text{O}$ [$y = x - 1$]. (*Acid vanadyl sulphate* $(\text{VO} \cdot \text{SO}_3)_2 \cdot \text{H}_2\text{SO}_4 \cdot y\text{H}_2\text{O}$.) Hydrates with $x = 4$ and 3 (or $y = 3$ and 2) were prepared by Gerland (*B.* 10, 2, 109); and a hydrate with $x = 6$ (or $y = 5$) by Crow (*C. J.* [2] 15, 455).

By dissolving V_2O_5 in a large excess of conc. H_2SO_4 , heating for a long time at c. 120° , and drying the small, blue, transparent crystals that formed on a porous tile over H_2SO_4 , Gerland obtained a substance which gave analytical results approaching those required by the formula $\text{V}_2\text{O}_5 \cdot 3\text{SO}_3 \cdot 4\text{H}_2\text{O}$. The salt was not obtained quite free from admixed $\text{V}_2\text{O}_5 \cdot 4\text{SO}_3 \cdot x\text{H}_2\text{O}$. This *tetrahydrate* was partially decomposed by cold water, giving lustrous scales which, after washing with alcohol and ether and drying over H_2SO_4 , had the composition of a *trihydrate*, $\text{V}_2\text{O}_5 \cdot 3\text{SO}_3 \cdot 3\text{H}_2\text{O}$.

Crow obtained a *hexahydrate* $\text{V}_2\text{O}_5 \cdot 3\text{SO}_3 \cdot 6\text{H}_2\text{O}$, by reducing by SO_2 a solution of V_2O_5 in conc. H_2SO_4 , heating at 100° for some time, drying the light-blue crystals that separated on a tile, removing acid by washing with ether, and drying by pressure between paper. The crystals deliquesced in air to a blue syrup; they were insoluble in ether, and scarcely soluble in absolute alcohol.

The formulæ of the various hydrated hypovanadic sulphates are as follows:—

<i>Hypovanadic sulphates</i> ;	or	<i>Divanadyl sulphates</i> ;	or	<i>Vanadyl sulphates</i> .
$\text{V}_2\text{O}_5 \cdot 2\text{SO}_3$		$\text{V}_2\text{O}_5 \cdot (\text{SO}_3)_2$		$\text{VO} \cdot \text{SO}_3$ (Gerland).
$\text{V}_2\text{O}_5 \cdot 2\text{SO}_3 \cdot 3\text{H}_2\text{O}$		$\text{V}_2\text{O}_5 \cdot (\text{SO}_3)_2 \cdot 3\text{H}_2\text{O}$		$2(\text{VO} \cdot \text{SO}_3) \cdot 3\text{H}_2\text{O}$ (G.)
$\text{V}_2\text{O}_5 \cdot 2\text{SO}_3 \cdot 4\text{H}_2\text{O}$		$\text{V}_2\text{O}_5 \cdot (\text{SO}_3)_2 \cdot 4\text{H}_2\text{O}$		$\text{VO} \cdot \text{SO}_3 \cdot 2\text{H}_2\text{O}$ (Crow, confirming Berzelius).
$\text{V}_2\text{O}_5 \cdot 2\text{SO}_3 \cdot 7\text{H}_2\text{O}$		$\text{V}_2\text{O}_5 \cdot (\text{SO}_3)_2 \cdot 7\text{H}_2\text{O}$		$2(\text{VO} \cdot \text{SO}_3) \cdot 7\text{H}_2\text{O}$ (G., also C.)
$\text{V}_2\text{O}_5 \cdot 2\text{SO}_3 \cdot 10\text{H}_2\text{O}$		$\text{V}_2\text{O}_5 \cdot (\text{SO}_3)_2 \cdot 10\text{H}_2\text{O}$		$\text{VO} \cdot \text{SO}_3 \cdot 5\text{H}_2\text{O}$ (G.)
$\text{V}_2\text{O}_5 \cdot 2\text{SO}_3 \cdot 13\text{H}_2\text{O}$		$\text{V}_2\text{O}_5 \cdot (\text{SO}_3)_2 \cdot 13\text{H}_2\text{O}$		$2(\text{VO} \cdot \text{SO}_3) \cdot 13\text{H}_2\text{O}$ (G.)
$\text{V}_2\text{O}_5 \cdot 3\text{SO}_3 \cdot 3\text{H}_2\text{O}$		$(\text{V}_2\text{O}_5)_2\text{H}_2(\text{SO}_3)_3 \cdot 2\text{H}_2\text{O}$		$2(\text{VO} \cdot \text{SO}_3) \cdot \text{H}_2\text{SO}_4 \cdot 2\text{H}_2\text{O}$ (G.)
$\text{V}_2\text{O}_5 \cdot 3\text{SO}_3 \cdot 4\text{H}_2\text{O}$		$(\text{V}_2\text{O}_5)_2\text{H}_2(\text{SO}_3)_3 \cdot 3\text{H}_2\text{O}$		$2(\text{VO} \cdot \text{SO}_3) \cdot \text{H}_2\text{SO}_4 \cdot 3\text{H}_2\text{O}$ (G.)
$\text{V}_2\text{O}_5 \cdot 3\text{SO}_3 \cdot 6\text{H}_2\text{O}$		$(\text{V}_2\text{O}_5)_2\text{H}_2(\text{SO}_3)_3 \cdot 5\text{H}_2\text{O}$		$2(\text{VO} \cdot \text{SO}_3) \cdot \text{H}_2\text{SO}_4 \cdot 5\text{H}_2\text{O}$ (G.)

ing V_2O_5 in hot conc. H_2SO_4 and boiling; (2) by dissolving V_2O_5 in conc. H_2SO_4 , reducing by SO_2 or $\text{H}_2\text{C}_2\text{O}_4$, and evaporating; (3) by dissolving V_2O_5 in conc. H_2SO_4 and boiling in the air for some time. In reaction (3) $\text{V}_2\text{O}_5 \cdot x\text{SO}_3$ seems to be formed and then partially reduced, by dust or products of combustion of coal-gas, to $\text{V}_2\text{O}_5 \cdot x\text{SO}_3$; the products are mixtures of $\text{V}_2\text{O}_5 \cdot x\text{SO}_3$ and $\text{V}_2\text{O}_5 \cdot x\text{SO}_3$ (Gerland, *B.* 11, 98).

Hypovanadic disulphate, or normal divanadyl sulphate, $\text{V}_2\text{O}_5 \cdot 2\text{SO}_3$, or $\text{V}_2\text{O}_5 \cdot (\text{SO}_3)_2$. (*Vanadyl sulphate* $\text{VO} \cdot \text{SO}_3$.) Prepared by Gerland (*B.* 10, 2109 [1877]; supplementing *B.* 9, 869) by dissolving V_2O_5 in a large excess of conc.

Bevan (*C. N.* 38, 294) obtained *divanadyl dithionate* by adding $\text{BaS}_2\text{O}_8\text{Aq}$ to $\text{V}_2\text{O}_5 \cdot (\text{SO}_3)_2\text{Aq}$, filtering, and evaporating *in vacuo*: the salt was not obtained pure. By dissolving V_2O_5 in HNO_3Aq Berzelius (*P.* 22, 1) obtained a blue liquid which probably contained *hypovanadic nitrate*; but no solid could be isolated, as on evaporation to dryness decomposition occurred, with formation of V_2O_5 . V_2O_5 also dissolves in $\text{H}_3\text{PO}_4\text{Aq}$; on evaporation at 50° blue crystals are obtained, which deliquesce to a blue syrup; these crystals are probably *hypovanadic phosphate*, but no analyses are given (*B. l.c.*). Berzelius obtained what were probably comp-

pounds of V_2O_5 with As_2O_3 , B_2O_3 , CrO_3 , MoO_3 , and a few other acidic oxides (*v. Lehrbuch* [5th ed.] 3, 1053).

VANADIUM PENTOXIDE V_2O_5 . (*Vanadic oxide. Vanadic anhydride.*) Mol. w. not known. Represented by Berzelius as VO_3 ($V=68.5$, $O=8$).

Formation.—1. By strongly heating any of the lower oxides in air or O .—2. By heating NH_4VO_3 in air to dull redness.—3. By decomposing $VOCl_3$ by water.—4. By heating $V_2O_3 \cdot 4SO_3$ 9aq to bright redness (Brierley, *C. J.* 49, 824).

Preparation.—Pure $VOCl_3$ is decomposed by water, and the ppt. V_2O_5 is washed till the washings are free from acid ($HClAq$ is produced) and heated until dry (Schafarik, *J. pr.* 76, 142). For the preparation of V_2O_5 from *vanadinite* and other sources of V compounds, *v. VANADIUM, Preparation* (p. 841).

Properties.—A pale-yellow powder, with a reddish tinge. When heated to full redness out of contact with any reducing agents, V_2O_5 melts, and solidifies on cooling to a mass of yellow-red, crystalline needles, appearing ruby-red by transmitted light; should the V_2O_5 used contain V_2O_3 , which is often the case when the V_2O_5 is prepared by heating NH_4VO_3 , the solid obtained by fusion and cooling appears violet to nearly black, and does not seem to be crystalline (Berzelius, *P.* 22, 1). As molten V_2O_5 cools nearly to its solidifying-point much heat is given out, and the mass glows until solidification is complete (*B., l.c.*). V_2O_5 is said not to be changed at a white heat, provided no trace of a reducing agent is present (*B., l.c.*); but according to Read (*C. J.* 65, 313 [1894]) molten V_2O_5 gives off O , producing V_2O_3 , which on cooling in air takes up O , forming steel-blue crystals of V_2O_3 . The crystals of V_2O_5 are rhombic (*v. Nordenskjöld*, *P.* 112, 160). S.G. (crystalline) 3.5 at 20° (Schafarik, *J. pr.* 76, 142). V_2O_5 is odourless and tasteless; it reddens moist litmus paper; 1,000 pts. boiling water dissolve scarcely 1 pt. V_2O_5 (*B., l.c.*). With molten alkalis or alkali carbonates V_2O_5 produces *vanadates* (*q.v.* p. 851). V_2O_5 dissolves in conc. H_2SO_4 , $HClAq$, HNO_3Aq , or $HFAq$ (*cf. VANADIC SALTS*, p. 850).

According to Ditte (*C. R.* 101, 698), V_2O_5 exists in three forms: (1) *red*, obtained by heating NH_4VO_3 in a closed crucible, treating with HNO_3 and repeatedly heating to redness; (2) *yellow*, obtained by heating NH_4VO_3 to 440° in a stream of air; and (3) *crystalline*, obtained by treating the yellow form with HNO_3 , and then fusing. D. says that the red form is somewhat soluble in water, 1,000 c.c. dissolving 8 g. at 20° ; that the yellow form is very slightly soluble, and the crystalline form is insoluble, in water. He also says that the red form absorbs water from the air, producing hydrates with $2H_2O$ and $5H_2O$; and that addition of $NHCl$, KCl (and other salts) to an aqueous solution of the red variety causes ppn. of a hydrate of the yellow form of V_2O_5 , which hydrate, when dry, is a dark-red powder having the composition $V_2O_5 \cdot 2H_2O$ ($=H_2V_2O_7$) and is almost insoluble in water. (No analyses are given by D.)

Reactions.—1. When heated and kept molten, V_2O_5 is formed, and this absorbs O as it cools in air and forms V_2O_3 (Read, *C. J.* 65, 313 [1894]). 2. Heated to redness in *hydrogen* till it ceases to lose weight, V_2O_5 is reduced to V_2O_3 (Schafarik, VOL. IV.

A. 109, 85); traces of P_2O_5 prevent the reduction (Roscoe, *C. J.* [2] 6, 331).—3. Heating with *potassium* produces V_2O_3 (Berzelius, *P.* 22, 1).—4. V_2O_5 is produced by heating V_2O_3 in a carbon crucible (*B., l.c.*). For action of Mg , Zn , &c. on solutions of V_2O_5 , *v. VANADIC SALTS*, (p. 850).—5. When mixed with *carbon* and heated in *chlorine*, V_2O_5 yields $VOCl_3$ (Roscoe, *C. J.* [2] 6, 342).—6. Electrolysis of molten V_2O_5 produces V_2O_4 (Buff a. Wöhler, *A.* 110, 277).—7. According to Ditte (*C. R.* 103, 55), fusion with *potassium cyanide* produces V_2O_3 (N , K_2O , and CO_2 being also formed). Carnot (*C. R.* 104, 1803, 1850; 105, 119) says that a *boiling solution of potassium cyanide* produces KVO_3 (CO_2 and N being given off); and that by dropping V_2O_5 into excess of boiling $KCNAlq$ there is formed $K_2V_4O_6$ (with evolution of N and CO_2). No analyses are given either by D. or C.—8. Ditte (*C. R.* 103, 55) asserts that the products of the interaction of V_2O_5 and *potassium iodide* or *bromide* are $K_2V_4O_6$, KVO_3 , and I or Br . The reactions are said to occur between V_2O_5 and molten KI or KBr ; and $KIAq$ is said to react in the same way as the molten salt.—9. When V_2O_5 is heated with molten *boron trioxide*, a pale-yellow glass is formed, which is said by Guyard (*Bl.* [2] 40, 354) to be a vanadic borate; no analyses, composition, or methods of purification are given.—10. V_2O_5 dissolves in *hot conc. sulphuric acid*, forming $V_2O_5 \cdot xSO_3$, generally along with more or less $V_2O_3 \cdot xSO_3$ (*v. VANADIC SALTS*, p. 850).—11. V_2O_5 dissolves in *conc. hydrochloric acid*; Cl is given off on heating; after the passage of H_2S followed by evaporation at 100° the oxychloride $VO_2Cl \cdot 2aq$ is obtained (Crow, *C. J.* 30, 457; *cf. VANADIUM DIOXYMONOCHLORIDE*, p. 854).—12. By dissolving V_2O_5 in *conc. hydrochloric acid* in presence of *platinic chloride*, Brauner (*M.* 3, 58) obtained large tablets having the composition $2(VOCl_2 \cdot PtCl_4) \cdot 21aq$.—13. An oxydide $2VO_2 \cdot 9aq$ is obtained, according to Ditte (*C. R.* 102, 1310), by adding excess of *hydriodic acid* to a warm aqueous solution of red V_2O_5 , removing free I by shaking with silver powder, filtering, and evaporating *in vacuo*. (No analyses are given).—14. V_2O_5 dissolves in *hydrofluoric acid*, forming a pale-yellow solution, the colour of which becomes deeper on dilution (Piccini a. Giorgis, *G.* 22 [1] 55). Petersen (*J. pr.* [2] 40, 271) supposed that a solution in conc. $HFAq$ contained VF_3 ; but he did not separate this compound, nor does he give any direct evidence in favour of its existence beyond the preparation from the solution of V_2O_5 in $HFAq$ of a compound which may be represented as $4KF \cdot VF_3 \cdot VOF_3$, and other compounds of the forms $xMF_3 \cdot yVOF_3$, and $xMF_3 \cdot yVO_2F$. By adding metallic fluorides to solutions of V_2O_5 in $HFAq$, and crystallising, vanadoxyfluorides are formed; these compounds are of the forms $xMF_3 \cdot yVOF_3$, and $xMF_3 \cdot yVO_2F$ (*v. VANADOXYFLUORIDES*, p. 844).—15. Vanadoxyfluorides are also formed by dissolving V_2O_5 in *alkali fluoride solutions*, and crystallising (*cf. infra, Combinations*, No. 5).—16. If a solution of V_2O_5 in *hydrofluoric acid* is partially reduced, and then evaporated with metallic fluorides, *hypovanadoxyfluorides* (*q.v.* p. 845) are formed; these salts are of the form $xMF_3 \cdot yVOF_2$.—17. *boiling* V_2O_5 with *hydrogen peroxide solution*, a

black liquid was obtained that deposited a black-brown crust of indefinite composition (Cammerer, *Chem. Zeit.* 19, 1957).—18. By fusion with *alkali* or *alkali carbonates* vanadates are formed (v. VANADATES, p. 851).

Combinations.—1. With *water*, but not directly, to form $V_2O_5 \cdot H_2O$ and $V_2O_5 \cdot 2H_2O$ (v. *Metavanadic acid* and *Pyrovanadic acid*, under VANADIUM OXYACIDS, AND SALTS AND DERIVATIVES THEREOF, p. 851).—2. With various *acidic oxides*: (1) With SO_2 to form $V_2O_5 \cdot xSO_2$, formed by dissolving V_2O_5 in hot conc. H_2SO_4 ; (2) with As_2O_3 to form $V_2O_5 \cdot xAs_2O_3$; (3) with P_2O_5 to form $V_2O_5 \cdot xP_2O_5$; (4) with IO_2 to form $V_2O_5 \cdot xIO_2$; (5) with MoO_3 to form $V_2O_5 \cdot xMoO_3$; (6) with WO_3 to form $V_2O_5 \cdot xWO_3$; (7) with P_2O_5 and SiO_2 to form $V_2O_5 \cdot xP_2O_5 \cdot ySiO_2$. Most of these compounds combine with the stronger bases M_2O and MO to form salt-like compounds. The compounds of V_2O_5 with SO_2 are described as *vanadic sulphates* under VANADIC SALTS (*infra*); the compounds with other acidic oxides are described respectively as *arseno-vanadic acids* and *salts*, *telluro-vanadic acids*, *molybdo-vanadic acids* and *salts*, *phospho-vanadic acids* and *salts*, *phospho-silico-vanadic acid*, and *tungsto-vanadic acids* and *salts*, under VANADIUM OXYACIDS, AND SALTS AND DERIVATIVES THEREOF (v. pp. 853-4).—3. With *vanadium tetroxide* to form oxides intermediate between V_2O_4 and V_2O_5 (v. HYPOVANADO-VANADIC OXIDES, p. 851).—4. With *vanadium trioxide* to form V_2O_4 ; produced by heating equivalent weights of the two oxides out of contact with air (Berzelius, P. 22, 1; Petersen, *J. pr.* [2] 40, 198).—5. With *alkali fluorides*. According to Ditte (C. R. 105, 1067; 106, 270), several compounds of the form $xV_2O_5 \cdot yMF$ are formed by fusing V_2O_5 with alkali fluorides, extracting with water, and crystallising; D. gives formulae where $x=1, 3$ and 4 , $y=1, 2, 4$ and 8 , and $M=K$ and Na ; but he does not give analyses of the salts (v. VANADOXYFLUORIDES, p. 844).

HYDRATES OF VANADIC OXIDE. The hydrates $V_2O_5 \cdot H_2O = HVO_3$ and $V_2O_5 \cdot 2H_2O = H_2V_2O_7$ have been isolated; these compounds are acids (v. VANADIC ACIDS, p. 851). Ditte (C. R. 101, 698) asserts, without giving analyses, that a pentahydrate $V_2O_5 \cdot 5H_2O$ is formed by absorption of water from the air by the red form of V_2O_5 (v. VANADIUM PENTOXIDE, *Properties*, p. 849).

VANADIC SALTS $V_2O_5 \cdot xX$ (X =acidic oxide). A few compounds of this form have been isolated. The sulphates have been better studied than the other salts. Two sulphates, $V_2O_5 \cdot 2SO_3 \cdot xH_2O$ and $V_2O_5 \cdot 3SO_3 \cdot xH_2O$, have been isolated. If x is taken to be 2 in the first salt and 3 in the second, then the formulae may be written as $(VO_2)_2SO_3 \cdot H_2SO_4 \cdot H_2O$ and $(VO_2)_2SO_3 \cdot 2H_2SO_4 \cdot H_2O$ respectively: $[(VO_2)_2SO_3 \cdot H_2SO_4 \cdot H_2O = V_2O_5 \cdot 2SO_3 \cdot 2H_2O$; $(VO_2)_2SO_3 \cdot 2H_2SO_4 \cdot H_2O = V_2O_5 \cdot 3SO_3 \cdot 3H_2O$]. If the salts are anhydrous, as seems most probable from the analyses, then the formulae may be written $(VO_2)_2SO_3 \cdot SO_3$ and $(VO_2)_2SO_3 \cdot 2SO_3$, respectively. Neither of the salts can be regarded as the normal salt. The sulphates are obtained by dissolving V_2O_5 in hot conc. H_2SO_4 .

Vanadic disulphate $V_2O_5 \cdot 2SO_3$ (? xH_2O). Prepared by Berzelius (P. 22, 89); examined also by Fritzsche (*J. pr.* 53, 98), Gerland (Z. 11,

98), and Münzig (C. C. 1889 (ii.) 908). The salt seems to be without water of crystallisation; F. (l.c.) says it crystallises with H_2O . V_2O_5 is dissolved in hot conc. H_2SO_4 , and the solution is boiled for a considerable time, when small crystals separate, some of which are brown and some ruby-red, lustrous, and transparent. The crystals are heated in a bath of molten lead until SO_3 ceases to be given off (G., l.c.). According to Münzig (l.c.), the orange-coloured crystalline powder that separates when V_2O_5 is added to boiling conc. H_2SO_4 until the acid is saturated is $V_2O_5 \cdot 2SO_3$. By keeping a solution of V_2O_5 in a large excess of conc. H_2SO_4 at 130° – 150° for a long time, Gerland (l.c.) obtained a hard, opaque, sealing-wax red, crystalline crust composed of V_2O_5 and SO_3 in approximately the ratio $V_2O_5 : 2SO_3$.

$V_2O_5 \cdot 2SO_3$ [= $(VO_2)_2SO_3 \cdot SO_3$] is described by G. (l.c.) as a clear red, crystals line, deliquescent solid; addition of a drop or two of water ppts. $V_2O_5 \cdot xH_2O$.

Vanadic trisulphate $V_2O_5 \cdot 3SO_3$ (? xH_2O). This salt seems to have been obtained by Berzelius (l.c.). Ditte (C. R. 102, 757) gave x the value 3; Gerland's analyses (l.c.) were inconclusive. The percentage of water found varying from .8 to 7.8. G. (l.c.) prepared this salt by long-continued boiling of a solution of V_2O_5 in a large excess of conc. H_2SO_4 ; small crystals separated, some of them brown and some ruby-red and transparent (probably regular octahedra). When the boiling was not continued for so long a time, G. noticed that fine, golden-yellow, lustrous needles separated. The composition of the crystals in each case was very nearly that required by the formula $V_2O_5 \cdot 3SO_3$. More or less $V_2O_5 \cdot 2SO_3$ was always formed; G. found that addition of a little $HClO_4$ prevented the formation of much $V_2O_5 \cdot 2SO_3$.

$V_2O_5 \cdot 3SO_3$ is very deliquescent; soluble in cold water or alcohol; a slight rise of temperature suffices to ppt. $V_2O_5 \cdot xH_2O$. By adding to a solution of this salt in cold water the proper quantity of K_2SO_4 , G. (l.c.) obtained small, amber-yellow crystals, which, after a few washings with cold water, pressure between paper, and drying over H_2SO_4 , had the composition of the *double salt* $V_2O_5 \cdot 2SO_3 \cdot K_2O \cdot 6aq$. The same crystals were obtained by using the disulphate $V_2O_5 \cdot 2SO_3$. Replacement of K_2SO_4 by $(NH_4)_2SO_4$ produced the *double salt* $V_2O_5 \cdot 2SO_3 \cdot (NH_4)_2O \cdot 4aq$. No double salts were obtained by using Na_2SO_4 or $MgSO_4$, but the trisulphate ($V_2O_5 \cdot 3SO_3$) crystallised unchanged.

Gerland (B. 11, 102) found that when a solution of V_2O_5 in hot conc. H_2SO_4 was largely diluted and dialysed, H_2SO_4 aq passed rapidly through the dialyser, along with small quantities of V compounds, until the liquid in the dialyser contained V_2O_5 and SO_3 in the ratio $V_2O_5 : 3SO_3$, after which SO_3 aq passed very slowly through, and the composition of the substance in the dialyser gradually approached $V_2O_5 \cdot 2SO_3$. By dialysing a diluted solution of V_2O_5 in cold conc. H_2SO_4 , the conditions being the same as in the experiment with the hot acid, G. found that SO_3 aq passed through the dialyser regularly, and that, after a time, the ratio of V_2O_5 to SO_3 in the dialyser was 1:1.82. G. supposed these results to mean that a solution of V_2O_5 in cold

H_2SO_4 contains loose, easily decomposed compounds of V_2O_5 and H_2SO_4 , but that a solution of V_2O_5 in hot H_2SO_4 contains $\text{V}_2\text{O}_5 \cdot 8\text{SO}_3$, which gradually loses SO_3 until $\text{V}_2\text{O}_5 \cdot 2\text{SO}_3$ is formed.

Solutions of V_2O_5 in conc. H_2SO_4 may be reduced to sulphates of lower oxides (Roscoe, *C. J.* [2] 6, 334; Rammeisberg, *B. B.* 1880. 787):—Zn, Cd, or Na-amalgam causes reduction to lavender solutions of $\text{V}_2\text{O}_5 \cdot x\text{SO}_3$; Mg effects reduction to green solutions of $\text{V}_2\text{O}_5 \cdot x\text{SO}_3$; and H_2S , SO_2 , or oxalic acid reduces only to blue solutions of $\text{V}_2\text{O}_5 \cdot x\text{SO}_3$.

By fusing V_2O_5 with B_2O_3 (Guyard, *Bl.* [2] 25, 354) obtained a green glass, which he took to be a *vanadic borate*; no analyses or descriptions are given.

The compounds of V_2O_5 with As_2O_3 , I_2O_5 , P_2O_5 , MoO_3 , and WO_3 respectively—or some of these compounds—may perhaps be regarded as vanadic arsenates, iodates, &c.; v. ARSENO-VANADIC ACIDS AND SALTS, IODO-VANADIC ACIDS, &c., p. 853.

HYPOVANADO-VANADIC OXIDES. Several oxides seem to exist intermediate between V_2O_5 and V_2O_4 . Roscoe noticed that V_2O_5 gradually absorbed O and H_2O from the air, forming a greenish solid; Brierley (*C. J.* 49, 30) found that a pale grass-green substance was formed after some months, having the composition $\text{V}_2\text{O}_5 \cdot 2\text{V}_2\text{O}_4 \cdot 8\text{aq} = \text{V}_2\text{O}_5 \cdot 4\text{aq}$. By dissolving this solid in dilute H_2SO_4 aq, and neutralising by KHOaq , B. obtained $2\text{V}_2\text{O}_4 \cdot 4\text{V}_2\text{O}_5 \cdot 5\text{K}_2\text{O} \cdot \text{aq}$. By gently heating the compound $2\text{V}_2\text{O}_4 \cdot 3\text{V}_2\text{O}_5 \cdot 3(\text{NH}_4)_2\text{O} \cdot 6\text{aq}$ (v. HYPOVANADO-VANADATES, p. 853), B. (*l.c.*) obtained a dark-green solid that absorbed water from the air, and then had the composition $3(\text{V}_2\text{O}_4 \cdot \text{V}_2\text{O}_5) \cdot 8\text{aq} = 3\text{V}_2\text{O}_4 \cdot 8\text{aq}$ (cf. Ditte, *C. R.* 101, 151; also Manasse, *A.* 240, 23).

Compounds of SO_3 with oxides intermediate between V_2O_5 and V_2O_4 are formed by the reducing action of zinc on solutions of V_2O_5 in H_2SO_4 (v. Rammeisberg, *B. B.* 1880. 787).

VANADIC OXYACIDS, AND SALTS AND DERIVATIVES THEREOF. Two oxyacids have been isolated, HVO_3 and $\text{H}_2\text{V}_2\text{O}_7$, corresponding with HPO_3 and $\text{H}_2\text{P}_2\text{O}_7$; salts of these, also salts of the tribasic acid H_3VO_4 , and several more complex salts, are known. Salts derived from the hypothetical hypovanadic acid $\text{V}_2\text{O}_4(\text{OH})_2 (= 2\text{V}_2\text{O}_4 \cdot \text{H}_2\text{O})$ have also been prepared; and several compounds are known which are most simply regarded as $x\text{V}_2\text{O}_4 \cdot y\text{V}_2\text{O}_5 \cdot z\text{MO}$, and which may be called hypovanado-vanadates. V_2O_5 also combines with several acidic and basic oxides simultaneously to form compounds of the general form $x\text{V}_2\text{O}_4 \cdot y\text{V}_2\text{O}_5 \cdot z\text{MO}$; these compounds are generally described as arseno-vanadates, phospho-vanadates, &c.

VANADIC ACIDS. Two vanadic acids, HVO_3 and $\text{H}_2\text{V}_2\text{O}_7$, have been isolated; salts of the third acid, H_3VO_4 , are known, but the acid itself has not certainly been prepared.

Metavanadic acid HVO_3 . (*Monobasic vanadic acid. Monohydrate of vanadic oxide $\text{V}_2\text{O}_5 \cdot \text{H}_2\text{O}$.*) Gerland (*B.* 9, 872 [1876]) prepared this acid by adding an excess of NH_4ClAq to cold CuSO_4Aq , then adding $\text{NF}_3\text{VO}_3\text{Aq}$ till a permanent pp. formed, heating to 75° , washing the lustrous yellow scales that slowly separated with dilute $\text{H}_2\text{SO}_4\text{Aq}$ and SO_2Aq (to remove V_2O_5), then washing with water, and drying at

100° until the smell of NH_3 ceased. Manasse (*A.* 240, 52) obtained HVO_3 by decomposing conc. solutions of the Ca, Mg, or Sr salt by a little HNO_3Aq , and washing the pp. with dilute HNO_3Aq , and then with hot water. Metavanadic acid forms golden-yellow crystalline scales; it is unchanged in air; dissolves very slightly in water; insoluble in absolute alcohol; soluble in NH_4Aq , KOHaq , or NaOHaq . By adding $\text{NH}_4\text{VO}_3\text{Aq}$ to CuSO_4Aq , filtering from the pp. that formed, and dialysing for several days, Gerland (*l.c.* p. 874) obtained a solution in the dialyser of vanadic acid, which remained clear when heated, and on continued evaporation gave a pp. of red amorphous V_2O_5 . Metavanadic acid forms a series of salts (v. METAVANADATES, *infra*).

This compound is used as a colour in place of gold bronze, under the name of *vanadium bronze*. According to Guyard (*Bl.* [2] 25, 356), the substance commonly known as vanadium bronze is really an ammonium vanadate.

Pyrovanadic acid $\text{H}_2\text{V}_2\text{O}_7$. (*Tetrabasic vanadic acid. Dihydrate of vanadic oxide $\text{V}_2\text{O}_5 \cdot 2\text{H}_2\text{O}$.*) This acid is obtained by decomposing a fairly conc. solution of an alkali vanadate of the form $\text{M}_2\text{V}_2\text{O}_7$, or $\text{M}_2\text{V}_2\text{O}_8$ (v. TETRAVANADATES and HEXAVANADATES, p. 852) by HNO_3Aq , washing with cold water, and drying in the air (von Hauer, *J. pr.* 80, 324). According to Ditte (*C. R.* 101, 698), the red form of V_2O_5 (v. p. 849) absorbs H_2O from the air, forming $\text{V}_2\text{O}_5 \cdot 2\text{H}_2\text{O}$, and also $\text{V}_2\text{O}_5 \cdot 5\text{H}_2\text{O}$. Pyrovanadic acid is described as a brown, amorphous powder, resembling $\text{FeO} \cdot \text{H}_2\text{O}$; dried over H_2SO_4 , it is said to lose half its water. Very slightly soluble in water; the solution is clear yellow; it reddens litmus. $\text{H}_2\text{V}_2\text{O}_7$ is insol. in absolute alcohol; it dissolves readily in NH_4Aq . For salts of this acid v. PYROVANADATES (p. 852).

VANADATES. The greater number of the vanadates belong to the series (1) MVO_3 , (2) $\text{M}_2\text{V}_2\text{O}_7$, (3) M_2VO_6 , (4) $\text{M}_2\text{V}_2\text{O}_{11}$, or (5) $\text{M}_2\text{V}_2\text{O}_8$. Series (1), (2), and (3) may be called normal salts; the formulae may be written as (1) $\text{M}_2\text{O} \cdot \text{V}_2\text{O}_5$, (2) $2\text{M}_2\text{O} \cdot \text{V}_2\text{O}_7$, and (3) $3\text{M}_2\text{O} \cdot \text{V}_2\text{O}_6$. Series (4) and (5) may be called acid salts; the formulae may be written as (4) $\text{M}_2\text{O} \cdot 2\text{V}_2\text{O}_7$, and (5) $\text{M}_2\text{O} \cdot 3\text{V}_2\text{O}_8$. Acid salts are also known intermediate between series (1) and (4); the chief of these are (6) $3\text{M}_2\text{O} \cdot 4\text{V}_2\text{O}_7 = \text{M}_2\text{V}_2\text{O}_{11}$ ($\text{M}_2\text{O} : \text{V}_2\text{O}_5 = 1:1\frac{1}{2}$), (7) $3\text{M}_2\text{O} \cdot 5\text{V}_2\text{O}_7 = \text{M}_2\text{V}_{10}\text{O}_{28}$ ($\text{M}_2\text{O} : \text{V}_2\text{O}_5 = 1:1\frac{1}{2}$), and (8) $2\text{M}_2\text{O} \cdot 3\text{V}_2\text{O}_8 = \text{M}_2\text{V}_6\text{O}_{20}$ ($\text{M}_2\text{O} : \text{V}_2\text{O}_5 = 1:1\frac{1}{2}$). A few salts of the form $4\text{M}_2\text{O} \cdot \text{V}_2\text{O}_7 = \text{M}_2\text{V}_2\text{O}_{11}$ ($\text{M}_2\text{O} : \text{V}_2\text{O}_5 = 1:1\frac{1}{2}$) may be called basic salts. Some salts, especially those of Sr and Tl, belong to more complex forms.

Roscoe (*C. J.* [2] 9, 28) has shown that the alkali orthovanadates, M_2VO_6 , or $3\text{M}_2\text{O} \cdot \text{V}_2\text{O}_6$, are easily decomposed in aqueous solution at the ordinary temperature to pyrovanadates, $\text{M}_2\text{V}_2\text{O}_7$, and MOHAq ; but that orthovanadates are formed, rather than meta- or pyro-vanadates, by fusing V_2O_5 with alkali carbonates; further, that aqueous solutions of alkali pyrovanadates are readily decomposed by CO_2 to alkali carbonates and metavanadates.

METAVANADATES $\text{M}'\text{VO}_3$ or $\text{M}_2\text{O} \cdot \text{V}_2\text{O}_5$.

Ammonium metavanadate NH_4VO_3 . Obtained by dissolving $\text{V}_2\text{O}_5 \cdot x\text{H}_2\text{O}$ in excess of NH_4Aq , warming, and allowing to evaporate

Forms a white, crystalline crust. Dissolves slowly in cold water, quickly in boiling water. Decomposed by heat, giving V_2O_5 when air is present. According to Berzelius (*P.* 22, 1), when a solution of $V_2O_5 \cdot xH_2O$ in excess of NH_4Aq is allowed to evaporate without having been heated, NH_4VO_3 separates in lemon-yellow crystals (*v. B.*, *l.c.*; Roscoe, *C. J.* [2] 6, 322; Ditte, *C. R.* 102, 918; Norblad, *B.* 8, 126; Wagner, *D. P. J.* 223, 633; Böttger, *C. C.* 1873, 514).

Barium metavanadate $Ba(VO_3)_2 \cdot aq$. A yellowish-white pp.; obtained, along with red crystals, by ppg. NH_4VO_3 by $BaCl_2Aq$ (Manasse, *A.* 240, 28). Sl. sol. in water. Loses H_2O when heated to c. 200° (Berzelius; Norblad, *l.c.*).

Potassium metavanadate $KVO_3 \cdot xaq$. Formed by dissolving V_2O_5 in $KOHAq$ in the ratio $V_2O_5:KOH$. Various hydrates have been obtained as white crystalline solids, melting to a clear yellow liquid, which solidifies to white, lustrous KVO_3 (*v. Berzelius, l.c.*; Ditte, *C. R.* 104, 902, 1061, 1168).

Sodium metavanadate $NaVO_3$. Obtained by Roscoe (*C. J.* [2] 9, 31) by fusing V_2O_5 and Na_2CO_3 in the ratio $V_2O_5:2Na_2CO_3$, dissolving in water, crystallising $Na_2V_2O_7 \cdot 18aq$, and passing CO_2 into an aqueous solution of this salt, when $NaVO_3$ crystallised out and Na_2CO_3 remained in solution. Small yellowish-white crystals, probably monoclinic prisms, melting readily and solidifying to a yellow crystalline mass (*cf. Norblad, l.c.*). Hydrates with 2, 4, and 5 H_2O have been obtained (*cf. Ditte, l.c.*).

The other metavanadates that have been prepared are $Cd(VO_3)_2$ (Ditte, *C. R.* 104, 1705); $Ca(VO_3)_2 \cdot 4aq$ (von Hauer, *J. pr.* 69, 385; 80, 324; Manasse, *A.* 240, 23; *cf. Roscoe, C. J.* [2] 9, 32); $Co(VO_3)_2 \cdot 8aq$ (D., *l.c.*; Radau, *A.* 251, 114), forms double salts with KVO_3 (R., *l.c.*); $Pb(VO_3)_2$ (R., *l.c.*; D., *l.c.*); $LiVO_3 \cdot 2aq$ (Ditte, *C. R.* 104, 1168); $Mg(VO_3)_2 \cdot 6aq$ (D., *l.c.*; Manasse, *l.c.*); $Mn(VO_3)_2 \cdot 4aq$ (Radau, *l.c.*); $AgVO_3 \cdot 4NH_3 \cdot 2aq$ (D., *l.c.*); $Sr(VO_3)_2 \cdot 4aq$ (Norblad, *l.c.*; Manasse, *l.c.*); $Zn(VO_3)_2 \cdot 2aq$ (D., *l.c.*).

ORTHOVANADATES $M_2V_2O_7$ or $3M_2O \cdot V_2O_5$.

Potassium orthovanadate K_2VO_6 . Obtained by fusing V_2O_5 with K_2CO_3 ; decomposed by water, giving $KOHAq$ and $K_4V_2O_7$ (Rammelsberg, *B. B.* 1883, 8).

Sodium orthovanadate $Na_2VO_4 \cdot xH_2O$. Roscoe (*C. J.* [2] 9, 29) obtained the salt with 16 H_2O by fusing V_2O_5 and Na_2CO_3 in the ratio $V_2O_5:3Na_2CO_3$, allowing to cool, dissolving in as little cold water as possible, quickly adding excess of conc. alcohol, allowing to stand for some hours, washing the crystals that formed with small quantities of alcohol, and drying on a porous plate over H_2SO_4 *in vacuo* (*cf. Ozudnowicz, P.* 120, 84; Rammelsberg, *B. B.* 1883, 8). Baker (*C. J.* 47, 853) obtained $Na_2VO_4 \cdot xH_2O$ with $x=8(?)$, 10, and 12; he also obtained the double salt $Na_2VO_4 \cdot NaF \cdot 19H_2O$. The crystalline forms are given by B., and the various hydrates of Na_2VO_4 are shown to be isomorphous with corresponding arsenates and phosphates. Na_2VO_4Aq changes to $Na_4V_2O_7Aq$ and $NaOHAg$; the change occurs slowly at ordinary temperatures, and rapidly at higher temperatures (R., *l.c.*).

The other orthovanadates that have been pre-

pared are $Ca_2(VO_4)_2 \cdot CaCl_2$ (Hautefeuille, *C. R.* 103, 600; 104, 501); $Pb_2(VO_4)_3$, and $3Pb_2(VO_4)_3 \cdot PbCl_2$ (R., *l.c.*); Ag_2VO_4 (R., *l.c.*); Tl_2VO_4 (Carnelley, *C. J.* 26, 323).

PYROVANADATES $M_2V_2O_7$ or $2M_2O \cdot V_2O_5$.

Barium pyrovanadate $Ba_2V_2O_7$. Obtained, as a white amorphous powder, by adding $BaCl_2Aq$ to freshly-prepared Na_2VO_4Aq , washing, and drying at 100° . The salt is slightly soluble in water (Roscoe, *C. J.* [2] 9, 33).

Potassium pyrovanadate $K_2V_2O_7$. Hard, deliquescent monoclinic prisms, formed by adding $KOHAq$ to KVO_3Aq , rapidly evaporating to a syrup, and placing over H_2SO_4 (Norblad, *B.* 8, 126).

Sodium pyrovanadate $Na_2V_2O_7 \cdot 16H_2O$. Formed by fusing V_2O_5 and Na_2CO_3 in the ratio $V_2O_5:2Na_2CO_3$, dissolving, and crystallising; also by exposing Na_2VO_4Aq to air free from CO_2 until addition of alcohol ppts. silly scales ($Na_2V_2O_7$) (Roscoe, *l.c.*, p. 31). White six-sided tables; e. sol. water, insol. alcohol. $Na_2V_2O_7Aq$ is decomposed by CO_2 to Na_2CO_3Aq and $NaVO_3Aq$ (R., *l.c.*).

The other pyrovanadates that have been prepared are $2Ca_2V_2O_7 \cdot 5aq$ (Roscoe, *l.c.*; *cf. Ditte, C. R.* 104, 1705); $Cu_2V_2O_7 \cdot 8aq$ (von Hauer, *l.c.*); $Pb_2V_2O_7$ (Ditte, *l.c.*); $2Pb_2V_2O_7 \cdot PbO$ (Roscoe, *l.c.*); $Li_2V_2O_7 \cdot 6aq$ (von H., *l.c.*); $Mn_2V_2O_7$ (Ditte, *l.c.*); $Ag_2V_2O_7$ (Roscoe, *l.c.*; Ditte, *l.c.*); $Tl_2V_2O_7$ (Carnelley, *C. J.* 26, 323); $Zn_2V_2O_7$ (D., *l.c.*).

TETRAVANADATES $M_4V_4O_{11}$ or $M_2O \cdot 2V_2O_5$ (also called *divanadates*).

Ammonium tetraivanadate $(NH_4)_4V_4O_{11} \cdot xaq$; $x=3$ or 4. Formed by adding a little acetic acid to boiling NH_4VO_3Aq and evaporating *in vacuo*; also by saturating NH_4Aq with V_2O_5 in a closed, warmed flask, and allowing to evaporate; red prismatic crystals with a golden-yellow sheen (Berzelius, *P.* 22, 1; Rammelsberg, *B. B.* 1883, 3; von Hauer, *l.c.*; Ditte, *C. R.* 102, 918).

Potassium tetraivanadate $K_4V_4O_{11} \cdot xaq$; $x=8$, 4, 7, and 10. Obtained by saturating K_2CO_3Aq at 80° with excess of V_2O_5 , and allowing to cool; also by adding acetic acid to V_2O_5 in $KOHAq$, concentrating at 80° , and letting cool (Ditte, *C. R.* 104, 902, 1061, 1168; *cf. Norblad, B.* 8, 126). Orange-coloured tablets (*v. also Gibbons, C. N.* 80, 267).

The other tetraivanadates are $Ca_4V_4O_{11} \cdot 9aq$ (Manasse, *A.* 240, 23); $Pb_4V_4O_{11}$ (Ditte, *l.c.*); $Li_4V_4O_{11} \cdot 9aq$ (Norblad, *l.c.*); $Mg_4V_4O_{11} \cdot 9aq$ (B., *l.c.*; von Hauer, *l.c.*); $Ni_4V_4O_{11} \cdot 8aq$ (Radau, *A.* 251, 114); $Na_4V_4O_{11} \cdot 9aq$ (Berzelius, *P.* 22, 1; von Hauer, *l.c.*; Norblad, *l.c.*); $Sr_4V_4O_{11} \cdot 9aq$ (B., *l.c.*; von H., *l.c.*).

HEXAVANADATES $M_6V_6O_{19} \cdot xH_2O$ or $M_2O \cdot 3V_2O_5 \cdot xH_2O$ (also called *trivanadates*). These salts have been described by Norblad (*B.* 8, 126) and Ditte (*C. R.* 104, 902, 1061, 1168). The chief are those where $M_2=(NH_4)_2$, Od , Ca , K , and Na .

The principal vanadates belonging to other series than those already mentioned are the following:—(1) $3M_2O \cdot 4V_2O_5$ ($=M_6V_6O_{20}$), $M=Ca$ and Sr (*v. Manasse, l.c.*); (2) $3M_2O \cdot 5V_2O_5$ ($=M_6V_6O_{21}$), $M=Ba, Mg, K$ (*v. Manasse, l.c.*; Radau, *A.* 251, 114); (3) $2MO \cdot 3V_2O_5$ ($=M_4V_4O_{17}$), $M=(NH_4)_2, Ba, Li, Mg, K, Na$ (*v. Ditte, l.c.*; also *C. R.* 96,

1048; Manasse, *l.c.*; Norblad, *l.c.*); (4) $4M_2O \cdot V_2O_5 (= M'_2V_2O_5)$, $M = Li$ and Na (*v. Ditte, l.c.*).

Several other vanadates not belonging to any of these series have also been described; for Ca and Sr salts (and double salts), *v. Manasse (l.c.)*; and for Tl salts *v. Carnelley (C. J. 26, 823)*.

HYPOVANADATES. Salts of hypothetical hypovanadic acid $V_2O_3(OH)_2 (= 2V_2O_3 \cdot H_2O)$. These salts belong to the form $M'_2V_2O_3 \cdot xH_2O (= M_2O \cdot 2V_2O_3 \cdot xH_2O)$. The formation of the NH_4 and K salts was described by Berzelius; a series of salts was prepared and examined by Crow (*C. J. [2] 15, 458*). The alkali salts are obtained by treating fairly conc. VO_2ClAq (*v. HYDRATED VANADIUM DIOXYMONOCHLORIDE, p. 854*) with excess of caustic alkalis, allowing the pps. to settle in closed vessels, washing with alkali solution, then with dilute alcohol containing a little acetic acid, and finally with alcohol alone, and drying between paper. The salts of Pb and Ag are obtained by ppn. from a solution of the K salt. The salts form brown to black crystalline powders; the alkali salts dissolve in water. Crow prepared salts with $M_2 = (NH_4)_2$, Ba , Pb , K_2 , Ag_2 , and NH_4 .

HYPOVANADO-VANADATES. Salts of the form $nV_2O_5 \cdot mV_2O_3 \cdot pM_2O \cdot xH_2O$. Alkali salts of this series were obtained by Brierley (*C. J. 49, 32*) by reducing V_2O_5Aq by SO_2 , adding V_2O_5 in alkali, then a slight excess of alkali, and then acetic acid; pouring into alkali acetate solution, washing the pps. with alcohol, and drying over $CaCl_2$. The salts crystallise in greenish-black, or black, prisms. The following were prepared: (1) $2V_2O_5 \cdot V_2O_3 \cdot 2Na_2O \cdot 0.13H_2O$; (2) $2V_2O_5 \cdot V_2O_3 \cdot 2K_2O \cdot 0.6H_2O$; (3) $2V_2O_5 \cdot 2V_2O_3 \cdot (NH_4)_2O \cdot 0.14H_2O$; these salts are soluble in water: (4) $2V_2O_5 \cdot 4V_2O_3 \cdot 5K_2O \cdot H_2O$; (5) $2V_2O_5 \cdot 4V_2O_3 \cdot 3(NH_4)_2O \cdot 0.6H_2O$; these are insoluble in water.

COMPLEX VANADIC ACIDS AND SALTS. Vanadic oxide V_2O_5 combines with several anhydrides, such as As_2O_3 , I_2O_5 , P_2O_5 , &c., and many of the compounds thus produced combine with basic oxides. The compounds of V_2O_5 with certain anhydrides are generally regarded as acidic; and the compounds formed of V_2O_5 , anhydrides, and bases are usually classed as salt-like substances. It is quite likely that many of the compounds of V_2O_5 with anhydrides, such as As_2O_3 , P_2O_5 , &c., would be better classed as salts, just as the compounds of V_2O_5 with SO_3 are classed as salts.

ARSENO-VANADIC ACIDS AND SALTS. By boiling V_2O_5 with excess of H_3AsO_4Aq , and concentrating the solution, Fernandez (*B. 17, 1632*) obtained lustrous, golden-yellow crystals of $V_2O_5 \cdot As_2O_3 \cdot 11aq$ (*cf. Friedheim a. Schmitz-Dumont, B. 23, 2600*). Gibbs (*P. Am. A. 21, 50*) obtained $xV_2O_5 \cdot yAs_2O_3 \cdot zaq$ (x and y probably either 5 and 8, or 7 and 6), by decomposing a mixture of Na vanadate and arsenate by HNO_3Aq . For various compounds of the form $mV_2O_5 \cdot nAs_2O_3 \cdot pMO$, where m and n are 1 and 1, 2 and 3, 1 and 2 and 1, &c., and p varies from 1 to 5, *v. F. a. S.-D. (l.c.)*.

IODO-VANADIC ACIDS. Ditte (*C. R. 102, 757*) says that compounds of V_2O_5 and I_2O_5 are formed by heating V_2O_5 with conc. HIO_4Aq ; he gives formulæ, but no analyses.

MOLYBDO-VANADIC ACIDS AND SALTS. For descriptions of numerous compounds of the forms $xV_2O_5 \cdot yMoO_3 \cdot zaq$, $xV_2O_5 \cdot yMoO_3 \cdot pMO \cdot zaq$, and also $xV_2O_5 \cdot yMoO_3 \cdot mP_2O_5 \cdot pMO \cdot zaq$, *v. Gibbs (P. Am. A. 18, 232)*.

PHOSPHO-VANADIC ACIDS AND SALTS. Various compounds of V_2O_5 , P_2O_5 , and H_2O are described by Gibbs (*P. Am. A. 21, 50*); Ditte (*C. R. 102, 757*) also assigned formulæ to substances obtained by heating V_2O_5 with conc. H_3PO_4 . Friedheim (*B. 23, 1530*) obtained $V_2O_5 \cdot P_2O_5 \cdot 2H_2O$ by dissolving V_2O_5 in syrupy H_3PO_4 .

For descriptions of a great many compounds of the form $xV_2O_5 \cdot yP_2O_5 \cdot mMO \cdot zaq$, *v. Gibbs (l.c.)*; and *cf. Friedheim (l.c.)*.

F. divides the compounds formed by reacting with V_2O_5 on alkali phosphates into two classes, which he calls *luteo-* and *purpureo-* compounds.

Luteo- compounds are formed by (1) the interactions of phosphoric and vanadic acids in solution; (2) the interactions of solutions of phosphates and vanadates in presence of small quantities of acids; (3) the interactions of solutions of phosphates and vanadic acid; (4) the interactions of vanadates and phosphoric acid, by heating solutions nearly to boiling and evaporating. These compounds are yellow, granular, and indistinctly crystalline; the alkali compounds are very slightly soluble in water, solution being accompanied by decomposition. The following luteo- compounds are described by F.: $V_2O_5 \cdot P_2O_5 \cdot 2H_2O \cdot 9aq$, $V_2O_5 \cdot P_2O_5 \cdot (NH_4)_2O \cdot H_2O \cdot 2aq$, $2V_2O_5 \cdot P_2O_5 \cdot (NH_4)_2O \cdot 7aq$, $V_2O_5 \cdot P_2O_5 \cdot K_2O \cdot H_2O \cdot 2aq$, and $2V_2O_5 \cdot P_2O_5 \cdot K_2O \cdot 7aq$.

Purpureo- compounds are formed by dissolving vanadic acid in conc. solutions of alkali phosphates, and by adding phosphoric acid to conc. solutions of alkali vanadates; in each case the solutions should be strongly heated. The purpureo- compounds described by F. belong to the form $12V_2O_5 \cdot P_2O_5 \cdot 7M_2O \cdot 26aq$; they are dark-red crystalline substances, sol. in water.

F. regards the luteo- compound of the form $V_2O_5 \cdot P_2O_5 \cdot 2H_2O \cdot 9aq$ as acid phosphate of the radicle VO_2 , thus $(VO_2)H_2PO_4 \cdot 9aq$; he compares this with the acid orthophosphates MH_2PO_4 . The compounds of the form $V_2O_5 \cdot P_2O_5 \cdot M_2O \cdot H_2O \cdot zaq$ are looked on as double acid phosphates of alkali metal and VO_2 , thus $NH_4(VO_2)HPO_4$. The luteo- compounds $2V_2O_5 \cdot P_2O_5 \cdot M_2O \cdot zaq$ are formulated by F. as double compounds of alkali metavanadates and $(VO_2)H_2PO_4$; thus $2V_2O_5 \cdot P_2O_5 \cdot K_2O \cdot 2H_2O \cdot 5aq = 2(KVO_3 \cdot (VO_2)H_2PO_4 \cdot 2\frac{1}{2}aq)$. The purpureo- compounds which belong to the form $12V_2O_5 \cdot P_2O_5 \cdot 7M_2O \cdot zaq$ are looked on by F. as double compounds of acid vanadates and acid phosphates; this view of their constitution is expressed by the statement

$12V_2O_5 \cdot P_2O_5 \cdot 7M_2O \cdot xH_2O = P_2O_5 \cdot 2M_2O \cdot H_2O + 12V_2O_5 \cdot 5M_2O + (x-1)H_2O$. These views of F. are considerably modified in a later paper (*Zeit. f. anorg. Chemie, 5, 437*), where the purpureo- compounds are looked on as divanadates with some V_2O_5 isomorphously replaced by P_2O_5 . According to F., many of the substances described by Gibbs and by Ditte do not exist.

Berzelius (*P. 22, 1*) described a compound

of V_2O_5 , P_2O_5 , and SiO_2 , with H_2O , which may be named *phospho-silico-vanadic acid*.

TUNGSTO-VANADIC ACIDS AND SALTS. The compounds of V_2O_5 with WO_3 and bases that have been described are very numerous, and the formulae given are generally extremely complex (*v. Gibbs, P. Am. A. 18, 232; Rosenheim, A. 251, 197, 234; and especially Friedheim, B. 17, 1505; 23, 1505; 24, 1173*).

Vanadium, oxybromides of. Two compounds of V with O and Br have been isolated; $VOBr_2$ and $VOBr_3$, corresponding with two of the five oxychlorides. According to Schafarik (*W. A. B. 33, 14; 47 [11] 251*), other oxybromides also exist.

VANADIUM OXYDIBROMIDE $VOBr_2$. (*Vanadyl dibromide*.) A brown, deliquescent powder. Prepared by heating $VOBr_3$ (*v. infra*); decomposition to $VOBr_2$ and Br occurs slowly at temperatures below 180° , and suddenly at 180° . Heated in air forms V_2O_5 ; dissolves in water, forming a blue solution (Roscoe, *C. J. [2] 9, 26*). Ditte (*C. R. 102, 1310*) says that a compound $VOBr_2 \cdot 4H_2O$ is formed, as dark-green, deliquescent crystals, by treating red V_2O_5 with HBr . D. writes the formula $V_2O_5Br_2 \cdot 2HBr \cdot 7H_2O$.

VANADIUM OXYTRIBROMIDE $VOBr_3$. (*Vanadyl tribromide*.) Prepared by passing vapour of pure Br over V_2O_5 heated to redness, condensing the yellowish-white vapours that are formed, removing excess of Br from the red liquid by heating to 40° – 50° at c. 100 mm. pressure in a current of perfectly dry air, and then distilling *in vacuo* (Roscoe, *C. J. [2] 9, 24*). $VOBr_3$ is a red, very hygroscopic liquid that boils at 130° – 136° at 100 mm. pressure; S.G. 2.9673 at 0° , 2.9325 at 14.5° ; decomposes slowly at the ordinary temperature, and suddenly at 180° , to $VOBr_2$ and Br (*R., l.c.*).

Vanadium, oxychlorides of. Five compounds of V with O and Cl have been isolated: $VOCl$, $VOCl_2$, $VOCl_3$, V_2O_5Cl , and VO_2Cl *zaq.*

VANADIUM OXYMONOCHLORIDE $VOCl$. (*Vanadyl monochloride*.) Obtained by the regulated reduction of $VOCl_2$ by H. The mixed vapours are passed through a red-hot tube; $VOCl$ is deposited near the end whereat the vapours enter the tube. A brown, light, flocculent powder; insol. in water; easily dissolved by HNO_3 aq (Roscoe, *C. J. [2] 6, 347*).

VANADIUM OXYDICHLORIDE $VOCl_2$. (*Vanadyl dichloride*.) Prepared by heating a slight excess of $VOCl_3$ with zinc for some days in a sealed tube, at 400° , cutting off the part of the tube on which the sublimate of $VOCl_2$ has formed (V_2O_5 and $ZnCl_2$ are the other products), quickly placing it in a wider tube, and removing $VOCl_3$ by heating in a stream of dry CO_2 at 130° . Also obtained by passing vapour of $VOCl_3$ and H through a red-hot tube; $VOCl_2$ is deposited near the end of the tube whereat the gases enter, and V_2O_5Cl at the further end of the tube (Roscoe, *l.c.*, p. 348). Lustrous, grass-green, deliquescent tablets; S.G. 2.88 at 13° ; slowly decomposed by water; soluble in dilute HNO_3 aq. A compound with $PtCl_4$, having the composition $2(VOCl_2 \cdot PtCl_4) \cdot 21aq$, is said by Brauner (*M. 3, 58*) to be formed by dissolving V_2O_5 in conc. $HClAq$ in presence of $PtCl_4$ aq.

VANADIUM OXYTRICHLORIDE $VOCl_3$. (*Vanadyl trichloride*.) Mol. w. 178.27.

Formation.—1. By heating V_2O_5 gently in a stream of Cl (Berzelius, *P. 22, 1*).—2. By heating a mixture of V_2O_5 and C in Cl.

Preparation.—A mixture of V_2O_5 and sugar-charcoal is heated to redness in a stream of dry H, and allowed to cool in that gas; a stream of dry Cl is then passed over the mixture, which is heated to redness, and the product is condensed; the liquid thus obtained is heated for some hours in a flask with an inverted condenser, in a current of dry CO_2 , and then rectified over Na (Roscoe, *C. J. [2] 6, 342*).

Properties and Reactions.—A clear, mobile, lemon-yellow liquid (Berzelius *l.c.*; Roscoe, *l.c.*; Schafarik, *A. 109, 85*). S.G. 1.836 at 17.5° , 1.828 at 24° (*R., l.c.*); 1.86534 at 0° , 1.63073 at b.p. (Thorpe, *C. J. 37, 348*). B.P. 127.19° (*T., l.c.*). S.V. 106.25. Does not solidify above -15° (*R., l.c.*). V.D. 88.38 at 186° (*R., l.c.*; cf. *T., C. N. 24, 827; Schafarik, l.c.*). Gives off thick, yellowish-red fumes in the air. Dissolves in a little water, forming a thick, red liquid; dissolves in much water, forming a clear yellow liquid; dissolves in absolute alcohol with a red colour, but the solution soon becomes blue, owing to reduction. Heated to 60° – 70° in a closed tube with ether forms needles of the composition $VOCl_2 \cdot Et_2O$ (Bedson, *C. J. 29, 309*).

DIVANADIUM DIOXYMONOCHLORIDE V_2O_5Cl . (*Divanadyl monochloride*.) Yellow-bronze, microscopic crystals, resembling *mosaic gold*; formed by passing $VOCl_3$ and H through a red-hot tube. The crystals are deposited on the part of the tube farthest from the end whereat the gases enter (Roscoe, *C. J. [2] 6, 348*). Insoluble in water; soluble in HNO_3 aq. This compound was thought by Schafarik (*A. 109, 85*) to be V.

HYDRATED VANADIUM DIOXYMONOCHLORIDE V_2O_5Cl *zaq.* (*Hypovanadic chloride* $V_2O_5Cl_2$ *zaq.*) Formed, as a brown, deliquescent solid, by passing H_2S into a solution of V_2O_5 in hot $HClAq$, filtering from S, and evaporating (Crow, *C. J. 30, 457*). Heated in a stream of dry CO_2 gives off HCl and H_2O , and leaves V_2O_5 . *C. (l.c.)* gives the hydration as $V_2O_5Cl_2 \cdot 5aq$.

Vanadium, oxyfluorides of. No compound of V with O and F has been isolated with certainty. V_2O_5 dissolves in excess of $HFAq$; on evaporation, solution in water, and evaporation over H_2SO_4 , Petersen (*J. pr. [2] 40, 194*) obtained blue, microscopic crystals which he supposed might be VOF_3 *zaq.* inasmuch as a solution of these crystals in $HFAq$ treated with fluorides yielded salts of the form xMF_yVOF_3 (*v. HYPOVANADOXYFLUORIDES*, p. 845). P. did not obtain enough of the blue crystals for analysis.

Vanadium, oxydides of. According to Ditte (*C. R. 102, 1310*), an oxydide $2VOI \cdot 9H_2O$ is formed, as a black, deliquescent mass, by adding excess of $HIAq$ to a warm solution of red V_2O_5 , removing free I by shaking with finely-divided Ag, filtering, and evaporating *in vacuo*. The compound is said to react with NH_3 aq, giving $(NH_4)_2V_2O_6$. D. writes the formula as $V_2O_5I_2 \cdot 2H_2O$; but no analyses are given.

No reaction occurs when I is heated with V_2O_5 (Roscoe, *C. J. [2] 9, 28*); nor when V_2O_5 is digested with water, or alcohol, and I (Guyard,

Bl. [2] 25, 351). V_2O_5 and I_2O_5 probably combine (v. Ditte, C. R. 102, 757, 1019).

Vanadium, oxysulphides of. None of these compounds has been certainly isolated. Oxy-sulphides may perhaps be formed by decomposing alkali thiovanadates in solution by dilute acids (v. Kay, C. J. 37, 728).

Vanadium, salts of. Compounds of the oxides V_2O_5 , V_2O_4 , and V_2O_3 with acidic oxides have been isolated; the formulæ of one or two of the compounds may be written as derived from oxyacids by replacing H by V, but it is simpler, and more in keeping with the facts that are known, to represent all the compounds by the general formula $V_2O_5 \cdot yX$, where X is an acidic oxide. The best-studied compounds of V_2O_5 with acidic oxides may be represented as salts, of the radicle V_2O_5 (divanadyl), or of the radicle VO (vanadyl); and the compounds of V_2O_4 with acidic oxides as acid salts of the radicle VO_2 . The sulphates have been better studied than the other salts; the following table presents the compositions of the sulphates.

I. *Vanadous sulphates* (v. p. 847):

II. *Hypovanadic sulphates* (v. p. 848):

III. *Vanadic sulphates* (v. p. 850):

Alkalis probably ppt. $V_2O_5 \cdot xaq$ from solutions of vanadous sulphates (v. p. 847); from solutions of hypovanadic sulphates alkalis ppt. $V_2O_5 \cdot xaq$ (v. p. 848).

V_2O_5 dissolves in oxyacids, forming lavender solutions which probably contain $V_2O_5 \cdot xX$, where X is an acidic oxide (v. p. 846).

Various salts of V_2O_5 , V_2O_4 , and V_2O_3 , besides the sulphates probably exist, but they have not been thoroughly examined (v. HYPOVANADIC SALTS, p. 848; VANADIC SALTS, p. 850; ARSENOVANADIC ACIDS AND SALTS, p. 853; IODO-VANADIC ACIDS, p. 853; MOLYBDO-VANADIC ACIDS AND SALTS, p. 853; PHOSPHO-VANADIC ACIDS AND SALTS, p. 853; and TUNGSTO-VANADIC ACIDS AND SALTS, p. 854).

Vanadium, silicide of. Roscoe (C. J. [2] 8, 858) says that V acts on glass or porcelain vessels when strongly heated therein, forming a compound with Si; tubes in which V chlorides are reduced by heating in H₂ get coated with a grey lustrous mirror of this compound. No details or analyses are given.

Vanadium, silicofluoride of. By boiling V_2O_5 with H_2SiF_6 and alcohol, Guyard (Bl. [2] 40, 352) obtained a greyish, uncrystallisable mass which he took to be a silicofluoride of V; no analyses or details of preparation are given.

Vanadium, sulphides of. Berzelius (P. 22, 1) described two compounds of V and S, one obtained by pyg. a solution of an alkali thiovanadate by dilute acid, and the other by heating V_2O_5 in H_2S . B. gave the formulæ VS_2 and

VS_2 to the compounds he described. The sulphides of V were re-examined by Kay in 1880 (C. J. 37, 728), who found that the pp. obtained by adding dilute $HClAq$ or H_2SO_4 to a solution of sodium vanadate saturated with H_2S , or to solution of V_2O_5 in an alkali hydrosulphide, contained O, but probably had not a definite composition; and that the product of heating V_2O_5 in H_2S is the trisulphide V_2S_3 ; Kay prepared three sulphides, V_2S_2 , V_2S_3 , and V_2S_4 , corresponding to three of the four oxides; the sulphides dissolve in solutions of alkali sulphides, probably forming thiovanadates (q. v. infra).

VANADIUM DISULPHIDE V_2S_2 . (*Hypovanadous sulphide*.) Prepared by heating V_2S_5 to full redness, for a long time, in H quite free from O. Forms black lustrous plates, or a brownish-black powder; S.G. 4.2 to 4.4. Absorbs O very quickly when heated in air, giving V_2O_5 , V_2O_4 , and then V_2O_3 , with evolution of SO_2 . Not acted on by boiling $HClAq$, dilute or conc., nor by boiling dilute H_2SO_4 , or cold conc. H_2SO_4 . Dissolves in hot conc. H_2SO_4 ; dissolves in HNO_3Aq . Slowly acted on by $NaOHAq$ or $KOHAq$, hot or cold; dissolves in $(NH_4)_2SAq$ or $KHSAq$, forming purple to reddish-brown solutions (Kay, l.c. p. 735).

VANADIUM TRISULPHIDE V_2S_3 . (*Vanadous sulphide*.) Formed by strongly heating V_2O_5 in a stream of H_2S (Berzelius, l.c.; Kay, l.c. p. 736); also by heating any chloride of V, or $VOCl_3$, to redness in H_2S (K., l.c.); and by strongly heating V_2O_5 in a stream of vapour of CS_2 , so long as any reaction occurs (K., l.c.). Forms dark, lustrous plates, or a black amorphous powder; S.G. 3.7 to 4.0. Oxidised by heating in air, finally to V_2O_5 , giving off SO_2 . Scarcely acted on by dilute $HClAq$ or H_2SO_4 , hot or cold, nor by conc. $HClAq$; readily oxidised by HNO_3Aq . Soluble in $(NH_4)_2SAq$ or $KHSAq$, forming purple-red to golden-red solutions; also somewhat soluble in $KOHAq$, $NaOHAq$ or NH_4OHAq (Kay, l.c.).

VANADIUM PENTASULPHIDE V_2S_5 . (*Vanadic sulphide*.) Prepared by mixing V_2S_3 with $\frac{1}{2}$ its weight of pure powdered S, heating to fusion (c. 400°) in a narrow tube quite filled with CO_2 and sealed, cooling, and dissolving out excess of S with CS_2 . A black powder; S.G. 3.0. Heated in a gas that does not react with it, V_2S_5 gives off S and leaves V_2S_3 ; heated in air gives off SO_2 , forming V_2O_5 , and finally V_2O_3 . Behaves towards acids similarly to V_2S_3 . Dissolves in hot $NaOHAq$; also in $(NH_4)_2SAq$ or $KHSAq$, forming yellow to red solutions (Kay, l.c. p. 738).

Vanadium thio-acids, and salts thereof. No compound of V with H and S has been isolated, but some thiovanadates, and also some oxythiovanadates, have been prepared by Krüss a. Ohnmais (B. 23, 2547).

Ammonium thio-orthovanadate $(NH_4)_2VS_4$. Obtained, in purple crystals, resembling $KMnO_4$, S.G. 1.62, by passing H_2S into a solution of NH_4VO_3 in NH_4Aq S.G. .898; the solution is saturated in the cold, and is kept cold while H_2S is passed in. A brown pp. is formed, and this dissolves after passing in more H_2S to a dark-violet liquid, from which the salt crystallises after some time.

Sodium monooxy-thio-orthovanadate $Na_2VOS_4 \cdot 5aq$. Obtained by saturating 80 c.c.

NaOHAq S.G. 1.122, with H_2S , adding a solution of 8 g. $\text{Na}_2\text{V}_2\text{O}_7$ in 6 c.c. water, cooling the liquid by ice, and passing in H_2S for 4 hours. The salt was also obtained without water of crystallisation by Krüss (*Zeit. f. anorg. Chemie*, 3, 264) by fusing a mixture of V_2O_5 , Na_2CO_3 , and S, until excess of S was removed. Small crystals, that melt at the ordinary temperature to a red, oily liquid (K. a. O., l.c.).

Sodium trioxy-thio-orthovanadate

$\text{Na}_2\text{VO}_3\text{S}$. 10aq. Obtained by heating $\text{Na}_2\text{V}_2\text{O}_7\text{Aq}$ to boiling, adding freshly prepared NaSHAq , cooling by ice, and adding alcohol. A red oil, that solidifies to a crystalline mass which melts at 18° (K. a. O., l.c.).

Ammonium monoxy-thio-pyrovandate

$(\text{NH}_4)_2\text{VO}_3\text{S}$. Formed by passing H_2S into a cooled solution of NH_4VO_3 in NH_4Aq S.G. greater than .898, and allowing the liquid to stand for some months, when crystals separate having S.G. 1.715 (K. a. O., l.c.).

Potassium monoxy-thio-pyrovandate

$\text{K}_2\text{VO}_3\text{S}$. 3aq. Obtained by passing H_2S into KVO_3 in KOHaq S.G. 1.472, air being excluded and the liquid cooled by ice. Crystals resemble KMnO_4 ; S.G. 2.144; loses all water slowly at 150° . By evaporating the mother-liquor from this salt *in vacuo*, large crystals of the salt $2\text{K}_2\text{VO}_3\text{S}$, 3aq are obtained (K. a. O., l.c.).

VERATRUM ALKALOIDS.

Veratrine $\text{C}_{22}\text{H}_{40}\text{NO}_6$. *Cevadine*. [205°]. S. 12 at 15° Occurs in the seeds of *Veratrum Sabadilla* (Meissner, *N. J. T.* 5, 3; Pellaier a. Caventon, *A. Ch.* [2] 14, 69; Couerbe, *A. Ch.* [2] 52, 352; Merck, *A.* 95, 200; *Ar. Ph.* 231, 135; Delondre, *J. Ph.* [3] 27, 417; Weigelin, *O. C.* 1872, 229; Schmidt, *Ar. Ph.* [3] 10, 511; B. 9, 1115; *A.* 185, 224). Occurs also in the root of *Sarracenia purpurea* (St. Martin, *Z.* [2] 2, 442; Hébet, *C. R.* 88, 185). Prepared by extracting

the seeds with boiling alcohol containing a little tartaric acid, concentrating the extract, adding water, filtering from resin, adding Na_2CO_3 , and shaking with ether. The ethereal solution is shaken with dilute tartaric acid solution, and the acid solution mixed with Na_2CO_3 , and extracted with ether. The ethereal extract is mixed with ligroin and allowed to evaporate spontaneously, when a viscid mass first separates, followed by crystals which are recrystallised from alcohol (Wright a. Luff, *C. J.* 33, 338). If commercial veratrine [144°] be dissolved in alcohol at 70° , water added till turbidity ensues, and the solution evaporated at 50° to 60° , crystalline veratrine separates first, then a resinous mixture of veratrine and veratridine, while the mother-liquor contains veratridine and veratrolin veratrate (Rosetti, *Ar. Ph.* [3] 21, 81).

Properties.—Needles (from alcohol), sol. ether, insol. water. Inactive to light. Very poisonous, a small quantity producing vomiting and purging. Introduced into the nose it produces sneezing. Alkaline to test papers. Conc. H_2SO_4 forms a yellow colour changing to crimson, 1 pt. colouring 3,000 pts. H_2SO_4 (Vasmer, *Ar. Ph.* 2, 74). Conc. HClAq forms a violet solution on warming. HNO_3 forms a red solution, becoming yellow. Veratrine mixed with sugar (3 pts.) is coloured by H_2SO_4 dark green and finally deep blue (Weppen, *Fr.* 13, 454). A solution of ammonium selenite (1 g.) in H_2SO_4 (20 c.c.) gives a yellow colour at 30° ; in 3 hours a red pp. is formed, the liquid remaining yellow (Da Silva, *C. R.* 112, 1267). On heating with alcoholic potash or baryta it yields angelic acid and cevine (W. a. L.; Rosetti; Stransky, *M.* 11, 482). ICl forms a yellow flocculent pp., sol. hot HClAq (Dittmar, *B.* 18, 1612). Conc. HClAq yields tiglic acid. Veratrine yields tiglic acid and (β)-methyl-pyridine on distillation. On distilling veratrine with lime the products are (β)-methyl-pyridine and its hexahydrate and isobutyric acid (Ahrens, *B.* 23, 2705). Veratrine is not affected by boiling dilute H_2SO_4 .

Salts.— B'HCl . Amorphous.— $\text{B}'_2\text{H}_2\text{PtCl}_4$: amorphous.— B'HAuCl_4 . Yellow needles (from alcohol).— $\text{B'HAuCl}_4\text{2aq}$ (Rosetti, *J.* 1883, 1851).— B'HHgCl_2 . Crystalline pp., v. sol. alcohol.— $\text{B}'_2\text{H}_2\text{SO}_4$ (dried at 100°).— B'HI . Reddish-brown amorphous solid (Bauer, *J.* 1874, 861).

Benzoyl derivative $\text{C}_{22}\text{H}_{38}\text{BzNO}_6$. [170° – 180°]. Brown crystals (containing $1\frac{1}{2}$ aq) (from ether).— B'HAuCl_4 .

Dibromide $\text{C}_{22}\text{H}_{38}\text{Br}_2\text{NO}_6$. Formed by allowing the tetrabromide to stand in contact with dilute KOHaq . Light-yellow amorphous solid.

Tetrabromide $\text{C}_{22}\text{H}_{38}\text{Br}_4\text{NO}_6$. Formed by shaking veratrine with bromine-water. Yellow amorphous powder, insol. water, v. sol. alcohol and ether (Ahrens, *B.* 23, 2701).

Cevine $\text{C}_{22}\text{H}_{42}\text{NO}_6$ (W. a. L.); $\text{C}_{22}\text{H}_{42}\text{NO}_6$ (Rosetti). *Cevadine*. [145°] (W. a. L.); [182° – 185°] (R.). Formed by boiling veratrine with alcoholic NaOH (W. a. L.). Yellow resin, v. sol. alcohol, sl. sol. ether. Its aqueous solution becomes turbid on warming. Does not attack the mucous membrane, gives a crimson colour with H_2SO_4 , and a brown colour with cane-sugar and H_2SO_4 . Its salts are amorphous.— B'HHgI , (dried at 100°). Precipitate.

Veratridine $C_{27}H_{33}NO_{11}$ (W. a. L.); $C_{27}H_{34}NO_{11}$ (Rosetti). *Veratrine*. [180° cor.] (W. a. L.); [150°-155°] (R.). S. 8 at 15°. If the viscid mass which separates before veratrine when a solution of the crude base in alcohol-ligroin is evaporated be shaken with ether, cevadilline remains undissolved, while veratridine dissolves in the ether (Wright a. Luff). Amorphous resin, sl. sol. ether. Decomposed by alcoholic potash into veratric acid and verine $C_{28}H_{35}NO_8$, [c. 95°] (W. a. L.) or veratroin $C_{33}H_{32}N_2O_{16}$ [143°-148°] (R.), an amorphous base, sol. ether. Veratridine dissolves in boiling water, being converted into veratroin veratrate $C_{33}H_{32}N_2O_{16} \cdot C_8H_8O_4$ (Rosetti), which melts, when anhydrous, at 165°-170°. H_2SO_4 forms a yellow solution which turns crimson.—Salts.— $B'HAuCl_4$. Amorphous.— $B'H_2SO_4$ 10aq, crystalline.

Cevadilline $C_{21}H_{25}NO_8$. Obtained as above (W. a. L.). Amorphous, sl. sol. ether, m. sol. benzene. Decomposed by alcoholic potash.

Salts.— $B'HAuCl_4$.— $B'HHgI_3$. Gelatinous. Cevadilline is perhaps identical with the sabadilline $C_{21}H_{25}N_2O_{13}$ of Wiegelin (*C. C.* 1872, 229), to which Hesse (A. 192, 186) assigns the formula $C_{21}H_{35}NO_8$; while sabatrine $C_{33}H_{34}N_2O_{17}$ (W.) or $C_{30}H_{35}NO_8$ (H.) was probably a mixture of decomposition-products (Wright a. Luff).

Veratrum album. The alkaloids in the root of this plant, and in that of *V. viride*, are described under JERVINE.

VERATRUMIC ACID is VERATRIC ACID.

VERINE v. VERATRUM ALKALOIDS.

VERININ $C_{18}H_{20}N_2O_8$ 3aq. Occurs in young vetch plants (*Vicia sativa*), in young red clover (*Trifolium pratense*), in pumpkin seeds, in ergot, and in the blossom of *Corylus avellana* and *Pinus sylvestris* (E. Schulze, *J. pr.* [2] 32, 447; *H.* 10, 80, 326). Separated from asparagin by crystallisation from hot water. Minute silky prisms, v. sol. hot water, insol. alcohol. Its aqueous solution is neutral, gives no pp. with $Pb(OAc)_2$, but is ppd. by $AgNO_3$, by picric acid, and by phosphotungstic acid in presence of HCl. Boiling hydrochloric acid forms guanine.— $Ag_2C_{18}H_{18}N_2O_8$. Gelatinous pp.

VERNONIN $C_{10}H_{21}O_7$. Occurs in the root of *Vernonia nigritiana*, used on the west coast of Africa as a febrifuge (Heckel a. Schlagdenhauffen, *C. R.* 106, 1446). White powder, sl. sol. ether and chloroform, sol. alcohol. Conc. H_2SO_4 gives a brown colour, changing to purple. Cardiac poison, 80 pts. being required to produce the effect of 1 pt. of digitalin. Decomposed by boiling dilute HCl into glucose and a resin $C_4H_{10}O_4$.

VIOLIN $C_{26}H_{31}N_1O_{21}$. S. 1 at 23°. Occurs in the seeds of *Vicia sativa*, *V. Faba*, and *V. Faba minor* (Ritthausen, *J. pr.* [2] 2, 333; 24, 202; 29, 359). Obtained by extracting the seeds with cold dilute H_2SO_4 (1:50), neutralising with lime, filtering from $CaSO_4$, evaporating to dryness and crystallising from 85 p.c. alcohol. The yield is 25 p.c.

Properties.—Tufts of small needles, nearly insol. alcohol. Loses $2H_2O$ at 160°. Sol. alkalis and alkaline earths, reppd. on neutralisation. Not affected by boiling baryta-water. Sol. dilute HCl and H_2SO_4 , but after boiling the solution gives a deep-blue colour with $FeCl_3$ and

NH_3 , and a violet pp. with baryta. Boiling KOHAq (S.G. 1.1) also forms divicin. When evaporated with HNO_3 (S.G. 1.2) the residue is edged with deep violet. Potash-fusion forms KCy.

Salts.— $B'_4H_2SO_4$.— B'_11HCl . Slender needles.

Divicin $C_{22}H_{28}N_2O_{16}$. By boiling vicin with water (5 pts.) containing H_2SO_4 (1 pt.) at 0° there is formed crystalline $(C_{22}H_{28}N_2O_{16})_2 \cdot 2\frac{1}{2}SO_4$, which yields divicin on treatment with exactly the calculated quantity of KOHAq. Flat prisms (from water). Reduces $AgNO_3$ at once. Not ppd. by baryta. A little $FeCl_3$ followed by NH_3 gives a splendid blue colour.— $B'8HNO_3$. Whetstone-shaped crystals, got by adding HNO_3 to a solution of divicin.

Convicin $C_{26}H_{32}N_2O_{14}$ 2aq. Obtained from powdered vetch seeds by extracting with alcohol, allowing vicin to crystallise from the extract, ppg. the mother-liquor with $HgCl_2$ and potash, decomposing the pp. with aqueous H_2S and evaporating. The mixture of vicin and convicin so obtained is treated with dilute H_2SO_4 , which dissolves the vicin only. Thin plates (from water), often resembling leucine. Hardly sol. cold water, sl. sol. alcohol. Not decomposed by boiling KOHAq (S.G. 1.1). Potash-fusion gives off NH_3 , but forms no KCy. Insol. cold dilute HCl and H_2SO_4 . Its aqueous solution gives a flocculent pp. with $Hg(NO_3)_2$.

VINACONIC ACID v. TRI-METHYLENE DICARBOXYLIC ACID.

VINCETOXIN $C_{16}H_{21}O_9$. [59°]. $[\alpha]_D = -50^\circ$. Extracted by milk of lime from powdered asclepias root (Tanret, *C. R.* 100, 277; *Bl.* [2] 43, 620). Occurs in two forms, one soluble and one insoluble in water. Both forms are levorotatory, amorphous, sl. alcohol, insol. ether. Boiling dilute HCl yields an amorphous, inactive sugar, which does not ferment with yeast.

VINYL ALCOHOL $CH_2:CH.OH$. This substance might be expected to be identical with aldehyde $CH_3.CHO$, but Polek a. Thümmel (*B.* 22, 2863) suppose it to be present in ether that has been exposed to air and sunlight, and that its presence is indicated by the formation of a pp. $C_2H_5OHgO.HgCl_2$ when a solution of mercury oxychloride in Na_2CO_3 aq is added to commercial ether. This pp. is white, and is converted by boiling potash into explosive greenish-black 'acetylene mercury' $C_2H_2O.Hg_2$, and by adding nitric acid to its alkaline solution into $C_2HHg_2OCl_2$, which is not explosive. H_2S passed into water containing the compound $C_2H_2O.Hg_2Cl_2$ yields (γ)-tri-thio-acetic aldehyde [76°].

VINYL-DIACETONAMINE v. ACETONAMINES.

VINYL-AMINE $CH_2:CH.NH_2$. Formed by the action of moist Ag_2O or of KOHAq on brom-ethylamine hydrobromide at 48° (Gabriel, *B.* 21, 1049, 2665). Known only in aqueous solution. Volatile with steam. Decomposes in aqueous solution even in the cold. SO_2 converts it into taurine.

Salts.— $B'HCl$. Poisonous. Its aqueous solution is decomposed by heat.— $B'_2H_2PtCl_4$. Crystals, v. sol. water.— B'_2BiI_3 . Minute scarlet hexagonal leaves.— $B'HAuCl_4$. Golden crystals.— $B'C_6H_5N_2O_7$. [142°]. Slender yellow needles.

References.—DI-iodovinylamine.

VINYL BROMIDE v. Bromo-ethylene.

Vinyl tribromide v. Tri-bromo-ethane.

VINYL CHLORIDE v. Chloro-ethylene.

VINYL ETHANE v. Butylene.

VINYL-ETHYL-CARBINOL v. Pentenyl alcohol.

VINYL-ETHYLENE v. Butinene.

VINYL ETHYL OXIDE $\text{CH}_2\text{:CH.OEt}$. (85.5° i.v.). S.G. $\frac{14.6}{17.5}$ 7625. Formed by heating chloro-acetal $\text{CH}_2\text{Cl.CH(OEt)}$, with sodium at 140° (Wislicenus, A. 192, 106). Liquid, smelling like ether mixed with allyl compounds. Combines with Cl and Br, forming di-chloro- and di-bromo-di-ethyl oxide. A small quantity (1 g.) of iodine converts large quantities of the oxide (200 g.) into a viscid liquid. Dilute (1:4) H_2SO_4 forms aldehyde and EtHSO_4 .

Reference.—Chloro-vinyl-ethyl oxide.

VINYL-ETHYL-PYRIDINE

$\text{C}_4\text{H}_5\text{N.Et.CH:CH}_2$. (98°–102° at 21 mm.). Formed by heating $\text{C}_4\text{H}_5\text{N.Et.CH}_2\text{CH}_2\text{OH}$ with conc. HCl at 170° (Prausnitz, B. 25, 2394). Oil, v. sol. ether.— $\text{B}'_2\text{H}_2\text{Hg.Cl}_{12}$. Needles, sl. sol. hot water.

VINYL IODIDE v. Iodo-ethylene.

VINYL-MALONIC ACID v. Trimethylene dicarboxylic acid.

VINYL OXIDE $(\text{C}_2\text{H}_3)_2\text{O}$. (39°). Formed by the action of dry Ag_2O on vinyl sulphide (Semmler, A. 241, 90).

Reference.—Hexa-chloro-di-vinyl oxide.

o-VINYL-PHENOL $\text{CH}_2\text{:CH.C}_6\text{H}_4\text{.OH}$.

Methyl ether $\text{CH}_2\text{:CH.C}_6\text{H}_4\text{.OMe}$. *o-Vinyl-anisole*. (c. 198°). S.G. $\frac{14}{30}$ 1-0095, $\frac{30}{30}$ 1-0005. Formed from either of the methyl derivatives of *o*-oxy-phenyl-acrylic acid by successive treatment with HI and $\text{Na}_2\text{CO}_3\text{Aq}$ (Perkin, C. J. 33, 211; 39, 429). Oil. Polymerises readily (at 150°), forming a glassy mass, which, however, on distillation, regenerates the original oil. It smells like high-boiling coal-tar naphtha. It forms a colourless compound with bromine. Forms a red solid with H_2SO_4 .

p-Vinyl-phenol. **Methyl ether** $\text{CH}_2\text{:CH.C}_6\text{H}_4\text{.OMe}$. [3°]. (205°). S.G. $\frac{14}{35}$ 1-0029; $\frac{35}{35}$ 9956. Formed by distilling methoxy-phenyl-acrylic acid (*q.v.*) and from the same acid by successive treatment with conc. HI (S.G. 1-94) and Na_2CO_3 .

Reference.—Bromo- and Nitro- vinyl-phenol.

VINYL-PIPERIDINE $\text{C}_8\text{H}_{10}(\text{C}_2\text{H}_5)_2\text{N}$ (?). (147°). Formed by dehydration of oxy-ethyl-piperidine [32°] (Ladenburg, B. 22, 2587). Liquid, smelling like tropidine and coniine, v. sol. water.

Reference.—Bromo-vinyl-piperidine.

p-VINYL-ISOPROPYL-BENZENE $\text{C}_{11}\text{H}_{14}$ i.e. $\text{C}_6\text{H}_5\text{Pr.CH:CH}_2$. (204°). S.G. $\frac{12}{28}$ 8902. Formed by distilling cumyl-acrylic acid at 210° or by boiling α -bromo- β -cumyl-propionic acid with $\text{Na}_2\text{CO}_3\text{Aq}$ (Perkin, C. J. 1877, ii. 660). Oil, smelling like cuminic aldehyde. Partially polymerises on boiling, and also on keeping, forming a glassy mass, reconverted into the original hydrocarbon by heat. Yields $\text{C}_{11}\text{H}_{11}\text{Br}_2$ [71°].

α -VINYL-PYRIDINE $\text{C}_5\text{H}_7\text{N}$ i.e.

$\text{N} \begin{array}{c} \diagup \text{C}(\text{C}_2\text{H}_5)\text{CH} \\ \diagdown \text{CH} \end{array} \text{CH}_2$. (159°). S.G. 2 9985. Formed by passing a mixture of pyridine and

ethylene through a red-hot tube (Ladenburg, B. 20, 1643). Formed also by distilling oxy-ethyl-pyridine under high pressure or in presence of KOH (Ladenburg, B. 22, 2585), and by the action of NaOHAq on β -bromo- β -pyridyl-propionic acid (Einhorn, A. 265, 229). Liquid smelling like conyryne, m. sol. water, v. sol. alcohol. Decomposed by distillation under atmospheric pressure, but boils at 81° under 29 mm. Oxidised by KMnO_4 to picolinic acid, and reduced in alcoholic solution by Na to ethyl-pyridine.—Salts: $\text{B}'_2\text{H}_2\text{PtCl}_6$. [174°]. Crystals, m. sol. water.— $\text{B}'\text{HAuCl}_4$. [144°]. Yellow needles.

Tetra-vinyl-pyridine $\text{C}_{11}(\text{C}_2\text{H}_5)_4\text{N}$. (277°). S.G. 2 1-0515. Formed in the preparation of γ -ethyl-pyridine by heating pyridine ethylo-iodide in sealed tubes at 320° (Karan, B. 25, 2776). Sl. sol. water.— $\text{B}'_2\text{H}_2\text{PtCl}_6$. [175°].— $\text{B}'\text{HAuCl}_4$. [148°].— $\text{B}'\text{HHgCl}_4$. [146°]. Needles.

VINYL-QUINOLINE v. Quinoly-ethylene.

VINYL SULPHIDE $\text{C}_2\text{H}_5\text{S}$ i.e. $\text{S}(\text{CH}_2\text{CH}_2)_2$. (101°). S.G. 913. Constitutes the chief part of the essential oil of *Allium ursinum* (Semmler, A. 241, 90). Liquid, smelling like allyl sulphide.

Reactions.—1. Dry Ag_2O forms vinyl oxide.—2. Moist Ag_2O gives aldehyde.—3. Alcoholic HgCl_2 forms crystals of $\text{C}_2\text{H}_5\text{Cl.Hg}_2\text{S}_2$, which, when heated with potassium sulphocyanide, yields vinyl sulphocyanide.—4. PtCl_4 added to its alcoholic solution ppts. $(\text{C}_2\text{H}_5)_4\text{Cl}_2\text{Pt}_2\text{S}_2$, which is decomposed by ammonium sulphide into vinyl chloride and dark-brown $(\text{C}_2\text{H}_5)_2\text{PtS}_2$.—5. AgNO_3 forms $(\text{C}_2\text{H}_5)_2\text{S.AgNO}_3$.—6. Br gives $(\text{C}_2\text{H}_5)_2\text{Br}_2\text{SBr}_2$ [195°].—7. *Oxidising agents* yield CO_2 , oxalic acid, and H_2SO_4 only.

VINYL-TOLUIDINE so called is Di-*p*-TOLYL-DI-ETHYLENE-DIAMINE.

VIOLAQUERCITBIN v. this vol. p. 373.

VIOLANTIN $\text{C}_8\text{H}_8\text{N}_2\text{O}_4$ 4aq. Formed by mixing hot conc. solutions of nitroso- and nitro-barbituric acids (violuric and dilituric acids). Formed also by warming hydruilic acid with dilute HNO_3 (Baeyer, A. 127, 223). Yellowish-white, crystalline powder, decomposed by water into its two component acids, but may be re-crystallised from HOAc or 50 p.c. alcohol. It is also split up into its components by salts of the stronger acids.

VIOLURIC ACID $\text{C}_4\text{H}_4\text{N}_2\text{O}_4$ i.e.

$\text{C}_2\text{O}_2 \begin{array}{c} \diagup \text{NH} \\ \diagdown \text{NH} \end{array} \text{C:NOH}$. Nitroso-barbituric acid. Mol. w. 157.

Formation.—1. From hydruilic acid by the action of nitric acid (S.G. 1-2) or nitrous acid (Baeyer, A. 127, 200).—2. By heating dilituric (nitro-barbituric) acid with glycerin.—3. By warming ferrous diliturate with KCy.—4. By boiling an aqueous solution of alloxantin with hydroxylamine hydrochloride (Pellizzari, G. 17, 258).—5. By adding hydroxylamine to an aqueous solution of alloxan (Ceresole, B. 16, 1133).—6. By adding KNO_2 to barbituric acid (Baeyer, A. 130, 140).

Properties.—Trimetric crystals (containing aq); $a:b:c = 83:1:1.92$. M. sol. cold water, al. sol. alcohol. Its aqueous solution is ppd. by alcohol. FeSO_4 gives a deep indigo-blue colour. HNO_3 forms nitro-barbituric acid. Br forms di-bromo-barbituric acid and nitrous fumes. Reducing agents form uranil (amido-barbituric

acid). Conc. HClAq forms hydroxylamine on heating.

Salts.— $\text{NH}_4\text{A}'$. Dark-blue prisms.— $\text{KA}'2\text{aq}$. Deep-blue crystals, v. sol. water, forming a blue solution; turned red by excess of KOH. A solution of the K salt in conc. HClAq deposits $(\text{KA}')_2(\text{HCl})$, 6aq in colourless efflorescent prisms.— BaA' , 4aq. Red dimetric tables, nearly insol. cold water.— MgA' , 6aq. Purple-red crystals.— PbA' , 4aq. Small red crystals.— AgA' .

Benzyl ether $\text{CO} \begin{smallmatrix} \text{NH.CO} \\ \text{NH.CO} \end{smallmatrix} \text{C.NOC}_2\text{H}_5$. [226°]. Formed by the action of benzyl chloride on silver violurate (Conrad a. Guthzeit, *B.* 15, 2849). Silvery scales, sol. hot water and alcohol.

VIRIDIC ACID v. CAFFETANNIC ACID.

VIRIDINE $\text{C}_{12}\text{H}_{19}\text{N}$. (251°). S.G. 1.024. A homologue of pyridine occurring in coal-tar (Thenius, *C. C.* 1862, 53). Yellowish oil, with slight greenish fluorescence, sl. sol. water, v. sol. alcohol and ether.— $\text{B}'_2\text{H}_2\text{PtCl}_6$. Greenish brown, insol. water, alcohol, and ether. The mercuric chloride double salt melts at 85° and crystallises from water.

Isomeride $\text{C}_{12}\text{H}_{19}\text{N}$. (230°–235°). Obtained, with other bases, by heating methyl-ethyl-acrolein with alcoholic ammonia (Hoppe-Seyler, *M.* 9, 651).— $\text{B}'\text{HAuCl}_4$. [93°].— $\text{B}'_2\text{H}_2\text{PtCl}_6$. [185°].

VISCIN $\text{C}_{10}\text{H}_{12}\text{O}_4$ (?). The glutinous constituent of the stalk, leaves, and berries of the mistletoe (*Viscum album*). Extracted from the bark by kneading with water, washing the sticky mass with 90 p.c. alcohol, and extracting the viscin with cold ether. The residue consists of viscaoutchin and woody-fibre (Reinsch, *C. C.* 1861, 145). Colourless, tasteless, semi-fluid mass, S.G. 1.0, decomposed by distillation, yielding oily viscene (226°) S.G. .85, which forms a crystalline Na salt with conc. NaOHaq. Viscaoutchin is very glutinous. Its S.G. is

3

.978, and it is insol. alcohol and ether, sol. oil of turpentine.

VISCOSE is DEXTRANE (*q. v.*).

VITELLIN v. PROTEIDS.

VITELLOSE v. PROTEIDS.

VOLUMES, SPECIFIC; v. SPECIFIC VOLUMES, p. 498.

VULPIC ACID $\text{C}_6\text{H}_7\text{O}_5$ i.e.

$\text{CPh:C(OH).C.CPh.CO}_2\text{Me}$. *Methyl pulvate*. $\text{CO} \text{---} \text{O}$

[148°]. Occurs in *Cetraria vulpina*, a lichen growing in Norway, and used there, mixed with nuxvomica, as poison for wolves (Bebert, *A.* 2, 342; Strecker a. Möller, *A.* 113, 56; Spiegel, *B.* 13, 1629; 14, 1686; *A.* 219, 15). The lichen contains $2\frac{1}{2}$ to 4 p.c. of the acid, which may be extracted by warm milk of lime. Vulpic acid is also formed by dissolving pulvic anhydride in a solution of KOH in MeOH. It appears to occur in the lichen *Parmelia parietina* (Berzelius; Stein, *J.* 1864, 553).

Properties.—Yellow plates or needles, sol. alcohol and ether, v. e. sol. chloroform, nearly insol. boiling water. Decomposed above 200° into MeOH and pulvic anhydride. Boiling milk of lime converts it into pulvic acid. Boiling KOHAq forms di-benzyl-glycollic acid and CO_2 .

Salts.— $\text{NH}_4\text{A}'$. Yellow crystals, sol. water.— BaA' , 2aq. Yellow needles (from water).— BaA' , 7aq.— KA' aq. Light-yellow needles, sl. sol. water.— AgA' . Pp. Blackens at 100°.

Acetyl derivative $\text{C}_{10}\text{H}_{11}\text{AcO}_4$. [156°]. Colourless needles, insol. NaOHaq.

Methyl ether v. Di-methyl ether of PULVIC ACID.

Isovulpic acid $\text{C}_{11}\text{H}_{11}\text{MeO}_5$. [124°]. Formed, in small quantity, together with pulvic anhydride, by heating vulpic acid at 200° (Spiegel). Thin golden plates (from alcohol). Forms orange solutions in alkalis.

W

WACKENRODER'S SOLUTION. The solution obtained by passing H_2S for a long time into nearly saturated SO_3Aq . The solution contains $\text{H}_2\text{S}_2\text{O}_8$, much $\text{H}_2\text{S}_2\text{O}_6$, $\text{H}_2\text{S}_2\text{O}_5$, and probably $\text{H}_2\text{S}_2\text{O}_4$, along with H_2SO_4 , dissolved colloidal S, and a little S in suspension; v. THIONIC ACIDS, p. 698.

WALDIVIN $\text{C}_{18}\text{H}_{21}\text{O}_{10}$. [230°]. S.G. 1.46. S. 17 at 15°; 8 at 100°. S. (alcohol) .53. Extracted by dilute alcohol from the powdered fruit of *Simaba waldivia* (Tanret, *Bl.* [2] 35, 104; *C. R.* 91, 886). Hexagonal prisms (containing 5aq), v. sol. chloroform, insol. ether. Neutral to litmus. Inactive to light. Tastes bitter.

WATER. H_2O . (*Hydrogen monoxide.*) Mol. w. 17.96. (For physical data v. *Properties.*)

Occurrence.—Pure water is never found in nature. The properties of different specimens of naturally occurring waters depend on the impurities they contain, and these impurities are derived from the substances with which the water has come into contact; hence it is customary to classify natural waters in accordance with their origin, as *rain-water*, *surface-water*,

well-water, *mineral spring-water*, and *sea-water*.

The composition of the substances found in these waters, and the properties of the waters themselves—that is, of the various more or less dilute aqueous solutions—are discussed in pp. 939–960 of vol. iv. of the DICTIONARY OF APPLIED CHEMISTRY. Solid water, more or less pure, is found as ice and snow. Water vapour is a constant constituent of the atmosphere. A great many minerals, and also many organic substances, contain water combined with other compounds.

Historical.—In 1781 Cavendish showed experimentally that water was the only product of burning H and O mixed in certain proportions, and that almost the whole of the H and O disappeared. The account of the experiments made by Cavendish was published in 1784 (*T.* 1784. 116).

*When a mixture of inflammable and dephlogisticated air [i.e. in modern language, hydrogen and oxygen] is exploded in such proportions that the burnt air is not much phlogisticated, the condensed liquor contains a little acid, which is always of the nitrous kind . . . ; but if the proportions be such that the burnt air is almost entirely phlogisticated, the condensed liquor is not at all acid, but

seems pure water, without any addition whatever; and as, when they are mixed in that proportion, very little air remains after the explosion, almost the whole being condensed, it follows that almost the whole of the inflammable and dephlogisticated air is converted into pure water' (*l.c.* p. 183).

Translated into modern language, this statement would be taken as asserting that water is formed by exploding a mixture of H and O in proper proportions. It is, however, worthy of note that Cavendish did not himself interpret his experimental results as we interpret them to-day. He regarded 'dephlogisticated air' [oxygen] as 'nothing but dephlogisticated water, or water deprived of its phlogiston.' He said: 'We must allow . . . that inflammable air [hydrogen] is either pure phlogiston . . . or else water united to phlogiston' (*l.c.* pp. 137, 140).

The formation of water by burning H and O was thought of by Cavendish as the restoration of phlogiston to water that had been deprived of this principle. 'Water,' he said, 'consists of dephlogisticated air united to phlogiston.' Cavendish evidently thought of H and O as what we might now call *forms of water*; one of these was water with too little phlogiston, and the other was water with too much phlogiston; the explosion restored the phlogistic balance, and the properties of water were apparent. When Lavoisier had interpreted Cavendish's results, Cavendish spoke of Lavoisier's explanation as an hypothesis: 'According to this hypothesis we must suppose that water consists of inflammable air united to dephlogisticated air' (*l.c.* p. 150). Cavendish established the fact that water is the product of burning a mixture of H and O in the ratio (approximately) of 2 vols. H to 1 vol. O; but he stated this fact in language that no longer carries a definite meaning with it. Lavoisier added to the experimental basis whereon the fact rested, and he expressed the fact in language that still is clear, definite, and descriptive.

Formation.—1. By the direct union of H and O by igniting a mixture of these elements. 2. By deoxidising metallic oxides, and many other compounds that contain O, by heating with H.—3. By the decomposition of many compounds containing H and O, by heat, or by reactions with other substances.

According to Freyer a. V. Meyer (*B.* 25, 622), a mixture of H and O in the ratio 2H:O does not explode when slowly passed through a glass tube at 606°, and the temperature of ignition of the wet, gaseous mixture is between 650° and 730°. Askenasy a. V. Meyer (*A.* 269, 49) found that when pure, dry electrolytic gas was passed at a moderate rate through a glass tube heated to 518°, only c. 7 to 1.7 mgms. of water were produced in ten hours; and that a little more water, but still only a very small quantity in proportion to the total quantity of H and O, was formed at 606°. Experiments made to determine the relation between the quantity of water formed and the time of the experiment showed that no constant relation could be arrived at, even when every precaution was taken to insure equality of conditions; the irregular action of the surfaces of the vessels was probably the cause of the irregularities in the results.

Davy (*T.* 1817) found that electrolytic gas did not explode when the pressure was so reduced

that the gas was rarefied to $\frac{1}{10}$ of its ordinary density. Thomas (*C. J.* 35, 215) found that the gas exploded at 168 mm. pressure. L. Meyer a. Seubert (*C. J.* 45, 586) found that the sparks from a Ruhmkorff coil caused the combination of c. $\frac{2}{3}$ of a quantity of electrolytic gas at c. 70 mm. pressure, and that the remainder combined when the pressure was increased until it became the same as before the first explosion; this result is in keeping with Bunsen's determinations of the quantity of oxygen needed to prevent the explosion of 2H + O (*v. M. a. S., l.c.* p. 588). Dixon (*T.* 1884, 634) noticed that electrolytic gas did not explode at a pressure under 70 mm., but that explosion occurred under 75 mm. pressure (*cf. D., l.c.* p. 642).

According to the experiments of Dixon (*l.c.*), 'the union of oxygen and hydrogen is not affected by the presence or absence of water'; dry electrolytic gas exploded by the spark at a pressure between 70 mm. and 75 mm., and the wet gas exploded at the same pressure.

The velocity of explosion of electrolytic gas was found by Berthelot and Vieille (*C. R.* 95, 151) to be 2,810 metres per second (*cf. Explosion*, vol. ii. p. 530).

Preparation.—Stas (*Chem. Proport.* 110) prepared pure water as follows. When large quantities were required, spring-water was *very slowly* distilled through a long copper tube, bent into zigzag form, completely filled with pure copper turnings that had been oxidised by strongly heating in O, the copper tube being surrounded by alumina and sand, and heated to full redness; the distillate was then distilled in an apparatus of platinum.

The second method recommended by Stas, especially when comparatively small quantities of pure water are required, is based upon destroying the organic matter in distilled water by the action of K manganate and permanganate. The process is described by Stas as follows:—

I prepared potassium manganate by reacting on manganese oxide with caustic potash and potassium chlorate. I shook up the powdered product with water, just sufficient to dissolve the manganate that had been formed, and allowed the mixture to settle in a closed vessel. I then added 4 or 5 p.c. of the clear, dark-green solution to the spring water which was to be distilled, and allowed the components of this mixture to react for 24 hours. I then poured into the distillation vessel one or two litres of the conc. solution of potassium manganate that had been mixed with an equal volume of conc. caustic potash solution; this solution of potash was sufficiently conc. to make the salt so stable that its dilute solution could be heated for a long time without decomposition. I then filled the distillation vessel to c. $\frac{3}{4}$ with the water which had been in contact with the potassium manganate, and distilled in the ordinary way. When boiling began I moderated the heat, in order to prevent the liquid, which frothed much for some minutes, from passing over. When the frothing has stopped, the water may be boiled rapidly without the least inconvenience. When $\frac{1}{4}$ of the water has distilled over, that which then distils is completely free from organic substances, and also from mineral substances, if the upper part of the distillation vessel is furnished with diaphragms to hold back the extremely small drops that are always carried forward when a liquid is boiled vigorously.

Stas says that water thus prepared is perfectly free from organic matter. When he wished to obtain water absolutely free from any form of solid matter, Stas re-distilled the water that had been purified as described above, using as condenser a long tube of platinum soldered with gold. It is advisable to distil the water just before it is to be used.

On one occasion Stas used rain-water instead of well-water, and he found distinct quantities of ammonia in the distilled water thus prepared. To remove this he recommends to re-distil with ~~some~~ part of NaHSO_4 or KHSO_4 .

Composition of water.—The gravimetric composition of water was determined by Berzelius (A. Ch. [2] 15, 86) and by Dumas (A. Ch. [3] 8, 189) by passing pure H over a weighed quantity of red-hot CuO , and weighing the water produced and the copper which remained. The results gave the ratio $\text{H}:\text{O}=1:8$ (B. a. D.) and $1:7.98$ (D.). An extended series of measurements by the same method, with many precautions, by Dittmar & Henderson (C. N. 67, 127, 139, 151, 164 [1893]) gave the ratio $\text{H}:\text{O}=1:7.9827$.

Several measurements have been made of the proportion by volume in which H and O combine to form water. Gay-Lussac in 1805, and Humboldt in 1805 (A. Ch. 53, 239), found the volumetric ratio of $\text{H}:\text{O}$ to be 2:1. Morley, in 1891 (Am. S. [3] 41, 220, 276), determined the ratio of $\text{H}:\text{O}$ to be 2.00023:1 by directly measuring the volumes of the gases. In 1892 Leduc (C. R. 116, 1248) found the ratio $\text{H}:\text{O}=2.0037:1$, from determinations of the relative densities of H, O, and electrolytic gas. In 1893 Scott (T. 184, 543) completed a most carefully performed series of syntheses of water by sparking mixtures of H and O, and determined the most probable value of the volumetric ratio $\text{H}:\text{O}$ to be 2.00245:1.

Properties.—Water is a clear, transparent, almost colourless, tasteless, odourless liquid. A column of water appears slightly blue when looked at lengthwise. Bunsen (A. 72, 44) pointed out that the slight blue colour of water may be observed by looking at a shining white object through a column of water 2 metres long, contained in a tube blackened inside. V. Meyer (B. 15, 297) recommends to join five wide, thin-walled glass tubes, c. 40 mm. internal diameter, and each c. $1\frac{1}{2}$ metres long, by wide caoutchouc tubing, and thus to form a tube c. $7\frac{1}{2}$ metres long; to lay the tube perfectly horizontal, and to close the end by smooth glass plates held in position by metallic clasps; then to cover the tube with black cloth. On looking through the tube the field of view appears quite colourless, but on now filling the tube with pure water (by means of brass tubes passing through the metallic clasps) a deep-blue colour is seen on looking through the column of water.

The boiling-point of water is 100° under the pressure of 760 mm. Zeuner (*Grundzüge der mechanischen Wärmetheorie*, Tab. 10 [1877]) gives the following table, showing the increase of boiling-point with increase of pressure:—

Pressure in atmos.	Boiling- point.	Pressure in atmos.	Boiling- point.
1 . . .	100	8 . . .	170.81
2 . . .	120.6	9 . . .	175.77
3 . . .	133.91	10 . . .	180.81
4 . . .	144	11 . . .	184.50
5 . . .	152.22	12 . . .	188.41
6 . . .	159.22	13 . . .	192.08
7 . . .	165.34	14 . . .	195.53

An elaborate table is given by Broch (*Trav. et Mém. du Bureau internat. des Poids et Mes.*,

1, 46 [1881]) based on Regnault's determinations; the table gives the b.p. of water for each .1 mm. from 680 to 800 mm. pressure. (The table is given in Landolt & Börnstein's *Physikalisch-Chemische Tabellen* [Berlin, 1883], pp. 47–49.)

The melting-point of ice is slightly lowered by pressure. J. Thomson (T. E. 16) calculated that the m.p. would be lowered by $n \cdot 0075^\circ$ for an increase of n atmospheres; W. Thomson (P. M. [3] 37, 123) confirmed this calculation by determining the m.p. of ice at 8.1 and 16.8 atmos. Mousson (A. Ch. [3] 56, 252) kept water liquid at -5° by greatly increasing pressure, and he found that at c. 13,000 atmos. pressure ice melted at -18° .

The specific gravity of water is greater at 4° than at any other temperature. Exner gives the temperature of maximum density as 3.945° (older determinations are tabulated by Exner, W. A. B. 68 (ii.), 463 [1873]). The following table, showing the density and volume of water from 0° to 100° , is given by Volkmann (W. 14, 260 [1881]); it is based on the determinations of Hagen, Matthiessen, Pierre, Kopp, and Jolly:

Temp.	Density (in vacuo) i.e. wt. of 1 c.c. water in grams.	Volume of 1 gram water in c.c.
0	.999878	1.000122
1	.999933	1.000067
2	.999972	1.000028

100	.95856	1.04322

Rossetti (*P. Ergänsbd.* 5, 268 [1871]) gives the densities and volumes of water for each degree from -10° to 100° , referred both to water at 0° and to water at 4° as unity. The S.G. of ice is c. .916 at 0° (water at $0^{\circ}=1$); according to recent determinations by Zakrzewski (*W.* 47, 155 [1893]) the value is .916660.

The expansion of water for various intervals of temperature has been measured by various observers; putting $V_t = V_0 (1 + at + bt^2 + ct^3)$, the following values are given by Kopp (*P.* 72, 1 [1847]; cf. Pierre, *P.* 86, 451; Weidner, *P.* 123, 800; Matthiessen, *P. M.* [4] 81, 149; Rossetti, *P. Ergänsbd.* 5, 258; Hirn, *A. Ch.* [4] 10, 32):

Temp.	a	b	c
0° to 25°	-.000061045	.0000077183	-.00000003734
25° to 50°	-.000065415	.0000077587	-.000000035408
50° to 75°	-.00005916	.0000031849	.0000000072848
75° to 100°	-.00008645	.0000031892	.0000000024487

For the expansion of water above 100° v. Mendeléeff (*A.* 119, 1).

As water freezes it expands by c. $\frac{1}{11}$ of its volume; one volume of water at 0° becoming 1.09082 volumes of ice at 0° . It expands when heated at temperatures below 0° ; Zakrzewski (*W.* 47, 155) gives the co-efficient of expansion .000077 (v. also Brunner, *P.* 64, 116; Struve, *P.* 66, 298; Marchand, *J. pr.* 35, 254).

The compressibility of water is small. Röntgen a. Schneider (*W.* 33, 644) give the absolute compressibility at 17.95° as .0000462 per atmosphere of pressure (v. also Ramsay a. Young, *T.* 1892; and cf. Grassi, *A. Ch.* [3] 81, 437; and Rankine, *P. M.* [4] 1, 548; also Amaury a. Descamps, *C. R.* 68, 1564; and Cailliet, *C. R.* 75, 77).

A table showing the volume of 1 kilo. of

saturated water vapour and the weight (in kilos.) of 1 c. metre of the vapour, at temperatures from 0° to 200° , is given by Zeuner (v. Landolt a. Börnstein's *Physikalisch-chemische Tabellen* [Berlin, 1883], p. 53; cf. Dieterici, *W.* 38, 1). According to Dieterici (*l.c.*) water vapour saturated at 0° behaves like a perfect gas.

The vapour pressure of water varies from 1.0288 mm. at -19° to 20926.4 mm. at 230° ; for complete tables calculated from Regnault's determinations v. Landolt a. Börnstein's *Physikalisch-chemische Tabellen* [Berlin, 1883] pp. 40-46 (the vapour pressure is given for each 1° from -19°

to 101° , and for each 1° from 101° to 230°). Ramsay a. Young (*T.* 1892) give a table of the vapour pressures of water up to 270° . In connection with the vapour pressures of water and ice, v. R. a. V. (*T.* 1884, 470). For an expression representing the vapour pressure of water at any temperature up to 325° , v. Antoine (*C. R.* 113, 828).

The spec. heat of water increases as temperature rises; the quantity of heat required to raise 1 g. of water from t° to $t^{\circ}+1$ is taken as unity in determinations of the spec. heats of other substances. The following table presents the data for S.H. of water at intervals of 10° from 0° to 230° (the memoirs by the different observers are: Regnault, *Acad.* 21, 729 [1847]; Jamin a. Amaury, *C. R.* 70, 661 [1870]; Bosscha, *P. Jubelbd.* 549 [1874]; von Münchhausen, *W.* 1,

t° (air therm.)	Regnault	Jamin a. Amaury	Bosscha	v. Münchhausen	Henrichsen	Baumgartner

592; 10, 284 [1877 and 1880]; Henrichsen, *W.* 8, 63 [1879]; Baumgartner, *W.* 8, 648 [1879]).

The following values for S.H. of water, from 0° to 35°, are given by Bartoli a. Stracciati (*A. Ch.* [6] 29, 285); the values in the column 'calculated' were obtained by using the formula:

$$\begin{aligned} \text{S.H.} &= 1.006630 \\ &- .000598962t \\ &+ .000004338650t^2 \\ &+ .000000425520t^3 \\ &- .000000002819t^4 \end{aligned}$$

The unit is the quantity of heat given out by 1 gram water at 15° in cooling to 14°.

t°	L.H. calcd.	S.H. observed.

The S.H. of ice is considerably less than that of water; Regnault's determinations gave .474 between -75° and 0°; the determinations of Person a. Desains gave .504 between -20° and 0°; Ramsay a. Young (*T.* 1884. 475) give the value .5 as the mean of various experiments. S.H. of water gas at 100° is given by Strecker (*W.* 17, 85) as .37 referred to an equal weight of water = 1, and 1.36 referred to an equal volume of air = 1; the ratio $\frac{\text{S.H.p.}}{\text{S.H.v.}}$ given by S. is 1.4,

Jaeger (*W.* 86, 165 [1889]) gave the value 1.33 to this ratio, and Cohen (*W.* 37, 628 [1889]) gave the value 1.287 for the temperature interval 144° to 300°.

The heat of vaporisation of water—i.e. the quantity of heat required to convert 1 g. of water at 100° into steam at 100°—is 535.77

gram-units, according to Favre a. Silbermann (*A. Ch.* [3] 37, 461). The following values are given for the heat required to convert 1 g. of water at t° completely into water vapour; 606.5 when $t = 0^\circ$, 637 when $t = 100^\circ$, 676.6 when $t = 230^\circ$ (Regnault, *Acad.* 21, 635); Dieterici (*W.* 38, 1) gives 596.8 when $t = 0^\circ$; Regnault (*l.c.*) gives the formula $\lambda = A + Bt$ for the total heat of vaporisation of water at different temperatures, and gives the values $A = 606.5$, $B = .305$.

According to Sakurai (*C. J.* 61, 495 [1892]), 'the temperature of the steam escaping from a boiling salt solution is exactly the same as that of the solution.'

The heat of fusion of ice, i.e. the quantity of heat required to convert 1 g. of ice at t° into 1 g. of water at t° is given as follows by different observers (the values are in gram-units of heat):—79.24 and 79.06 when $t^\circ = 0^\circ$ (Regnault, *A. Ch.* [3] 8, 19); 79.25 when $t = 0^\circ$, 74.2 when $t = -10^\circ$, 80.02 when t varies from -2° to -21° (Person, *A. Ch.* [3] 21, 295; 30, 73); 77.85 at -2.8° , 76.75 at -4.995° , 76.11 at -6.28° , 76.0 at -6.5° (Pettersson, *J. pr.* [2] 24, 129).

The thermal conductivity of water, from 10° to 18°, was determined by Winkelmann (*P.* 153, 481) to be .154; Bottomley (*Pr.* 31, 300) obtained nearly the same value; this figure means that heat sufficient to raise .154 mgrm. water from 0° to 1° passes per second through a layer of water 1 mm. thick and 1 sq. mm. area, when the difference between the temperatures of the two surfaces of the layer is maintained at 1°. For electrical conductivity of water v. *Reactions*, No. 2.

The refractive indices of water at different temperatures, and for different lights of determinate wave-lengths, have been measured by many observers. The following values have been found for μ_{D} : 1.33120 at 19.9°, 1.33091 at 23.7°, 1.33050 at 26° (Brühl, *B.* 24, 644). For detailed tabulation of the results obtained by Fraunhofer, van der Willigen, Baile, Damien, Landolt, Willner, and Rühlmann, v. Landolt a. Börnstein's *Physikalisch-Chemische Tabellen* [Berlin, 1883] 205; cf. also Perkin (*C. J.* 61, 293), who gives values for μ for the lines A C D and F, at 15° and 83.7°.

Observations have been made on the absorption spectrum of water and water-gas, but the matter has not been thoroughly investigated (v. Vogel, *P.* 156, 326; Jansen, *B.* A. 1866. 11).

Water crystallises, as ice, in rhombohedral forms; snow is generally found crystallised in six-sided stars derived from six-sided prisms.

Molecular weight of liquid water. Several observations have been made which tend to show that the molecular weight of liquid water is greater than 18. Paterno (*B.* 21, 3180), from measurements of the lowering of the freezing-point of water dissolved in acetic acid, concluded that the mol. w. might be 18, or might perhaps be 86. From the depression of the freezing-point of paratoluidine by water dissolved therein, Eykman (*Z. P. C.* 4, 510) concluded that the mol. w. of liquid water is probably 36, and this conclusion was strengthened by Walker's experiments on the connection between heats of fusion and solubility (*Z. P. C.* 5, 194). From measurements of the surface tension of water Ramsay and Shields (*C. J.* 63, 1089 [1893]) con-

clude that the mol. w. of liquid water is probably 72 at the ordinary temperature.

Reactions.—1. In 1847 Grove (*T.* 1847. 1) showed that water was decomposed into H and O by *heat*. Grove formed a little ball on the end of a Pt wire, by fusing the Pt, heated the globule of Pt to whiteness by an electric current, and plunged it into a little air-free water, nearly boiling, in a small basin, with a test tube full of air-free water arranged to collect any gas that might come off. Deville (*C. R.* 56, 195, 322 [1863]) found that H and O were given off in considerable quantities when molten Pt was plunged under water. D. noticed no decomposition when steam was passed through a Pt tube heated to bright redness, but by passing a current of an indifferent gas, such as CO_2 , through the hot tube, and thus sweeping away the products of decomposition, H and O were obtained.—2. Water is scarcely decomposed by an *electric current*. Kohlrausch found the electrical conductivity of the purest water he could obtain by distillation *in vacuo* to be 2.5×10^{-6} in C.G.S. units, or c. 72 billionths of the conductivity of Hg (*P. M.* [5] 18, 542). By calculations based on this result, Ostwald concluded that in a litre of pure water the weight of water dissociated into H and OH ions, expressed in gram-molecules, is 6×10^{-6} (*Z. P. C.* 11, 521). By other methods of calculation, based on other data, Ostwald arrived at the value 2 to 9×10^{-6} for what has been called the *dissociation constant* of water (*Z. P. C.* 11, 521); Wijs, by calculations based on the hydrolysis of methyl acetate, obtained the values 1×10^{-7} (*Z. P. C.* 11, 492), and 14×10^{-6} (*ibid.* 12, 514); Arrhenius obtained the value 1125×10^{-6} (*ibid.* 11, 827); and Bredig, the value 6×10^{-6} (*ibid.* 11, 829). Later experiments on the conductivity of water by Kohlrausch & Heydweiller (*Z. P. C.* 14, 316 [1894]) with water that had been distilled *in vacuo* ten years ago, had then stood in a vessel filled with water, and been again distilled *in vacuo*, gave the following results:—conductivity (Hg = 1) $\cdot 014$ at 0° , $\cdot 04$ at 18° , $\cdot 058$ at 25° , $\cdot 089$ at 34° , $\cdot 176$; all these to be multiplied by 10^{-10} . K. A. H. say that 1 mm. of this water at 0° had a resistance = that of 40 million kilometres of Cu wire of the same area. K. A. H. calculate that in 1 litre of the purest water at 18° there is $\cdot 00008$ mgm. H as free ions, and $\cdot 000105$ mgm. at 25° .—3. *Steam* is decomposed by *electric sparks*; for conditions and details of results *v.* Thomson (*Pr.* 53, 90).

The reactions of water are so many that an approximate classification of them into groups is all that can be attempted here.—4. Many *metals* react with water, at temperatures varying from the ordinary to a full red heat, forming oxides or hydroxides and giving off H. The following metals decompose cold water: Ba, Cs, Ca, (Ce ?), (La ?), Li, K, Rb, Na, Sr. Al, Fe, Pb, Mg, (? Mn), Mo, Ti react at c. 100° ; and most of the other metals at temperatures from c. 100° to a full red heat.—5. Many *non-metals* react, generally slowly, with water, forming acids and giving off O. F rapidly decomposes water at the ordinary temperature; Cl reacts slowly at the ordinary temperature, and somewhat more rapidly at a red heat; Br reacts more slowly than Cl; I has probably a very slight (? any) action. S and P react slowly at 100° ; Se is said not to

decompose water at 160° . Carbon gives off H at a red heat. *Boron* acts like a metal, giving off H at a red heat.—6. Many *haloid compounds* react with water, giving oxyhaloid compounds or oxides, and haloid acids.—7. Some *metallic sulphides* react with steam to form oxides and H_2S . 8. A few of the *lower oxides* decompose water; e.g. $\text{CrO} \cdot x\text{H}_2\text{O}$ at the ordinary temperature, and CO at c. 600° .—9. Water reacts with many *oxides* to form hydroxides which are either basic or acidic; in some cases hydrates are formed. Hydrates of various *salts* are also produced by combining the salts with water (*v.* HYDRATES, vol. ii. p. 703; *cf.* HYDROXIDES, vol. ii. p. 733).—10. Water *dissolves* very many compounds of the most different properties (*v.* SOLUTIONS, vol. iv. p. 484).

Small quantities of water often bring about chemical changes that do not occur when the substances are perfectly dry; for instance, a mixture of dry CO and O is not exploded by sparks, but a trace of water suffices to start the change (*v.* Baker, *C. J.* 65, 611 [1894]).

The acidic and basic characters of water are so nearly balanced that the compound cannot be classed among either acids or basic bodies. The chemical relations of water to the compounds formed by reactions between it and other substances are determined chiefly by the chemical characters of the substances that react with it; thus the relations of HOH to $\text{M}_x(\text{OH})_y$, formed by the interaction of water and metals, are those of an acid to its salts, whereas the relations of HOH to HX, formed by the interactions of water and non-metals, are those of a basic hydroxide to salts derived therefrom. The relations between both classes of derivatives of water and the parent compound are sometimes expressed by saying that the compounds belong to the *water type* (*v.* TYPES, vol. iv. p. 811). M. M. P. M.

WAX. A term applied to various natural solids more or less resembling bees'-wax. They are compound ethers, but differ from fats in yielding monovalent alcohols and not glycerin on saponification. They melt below 100° , are insol. water, sl. sol. or insol. alcohol, and sol. ether. They are not volatile.

Bees'-wax. [64°]. S.G. $\cdot 965$. Consists of a portion (about 5 p.c.) soluble in alcohol (cerin) and a portion insoluble in alcohol (myricin). Myricin is myricyl palmitate (Brodie, *A.* 67, 180; 71, 144). Cerin is chiefly composed of cerotic acid; but it contains small quantities of melissic acid $\text{C}_{26}\text{H}_{50}\text{O}_2$ [90°], and an acid melting at 78° (Schalfejeff, *B.* 9, 278, 1688; Natzger, *A.* 224, 246). There is also present one or more acids whose lead salts dissolve in ether and whose Ba salts dissolve in alcohol, and which therefore probably belong to the oleic series. Myricin may be saponified by alcoholic potash, and the myricyl alcohol separated from potassium palmitate by extraction with ligroin. Crude myricin yields CCl_4 and C_2Cl_4 when heated with I and excess of SbCl_3 at 400° (Hartmann, *B.* 24, 1022). Bees'-wax contains two hydrocarbons, one of which [80°] (c. 275° at 11 mm.) is probably *n*-heptacosane $\text{C}_{27}\text{H}_{56}$, and the other [68°] (c. 300° at 11 mm.) *n*-hentriacontane $\text{C}_{31}\text{H}_{64}$ (Schwalb, *A.* 235, 106). According to Schwalb, the myricyl alcohol of bees'-wax has the formula $\text{C}_{31}\text{H}_{62}\text{O}$ [85°], and is converted by heating with

soda-lime into an acid $C_{15}H_{31}O_2$ [89°], which forms a methyl ether [71°] and an ethyl ether [70°]. Among the products of saponification of bees'-wax, ceryl alcohol $C_{27}H_{54}O$ or $C_{26}H_{52}O$, and an alcohol $C_{25}H_{50}O$ or $C_{24}H_{48}O$ occur. The last-mentioned alcohol when heated with soda-lime gives an acid $C_{25}H_{50}O_2$ or $C_{24}H_{48}O_2$ [75.6°].

Carnauba wax v. vol. i, p. 710.

Chinese wax, which is produced by an insect, is almost entirely composed of ceryl cerotate ($C_{27}H_{54}O_2$) ($C_{27}H_{54}O_2$, (Brodie, A. 67, 199).

Cork wax v. CERIN.

Pine wax v. CEROPIC ACID.

Sugar-cane wax v. CEROSIN.

Japan wax [42°–55°]. Obtained in the East from *Rhus succedanea*. It appears to be really a fat, since palmitin is its chief component. It also contains the ether of a fatty acid of higher melting-point than stearic acid (Sthamer, A. 43, 343; Buri, Ar. Ph. [3] 14, 403).

Wax of Ficus gummiflua of Java contains an alcohol $C_{15}H_{30}O$ [73°], v. sol. ether, and a small quantity (5 p.c.) of isoceryl alcohol $C_{27}H_{54}O$, sl. sol. ether (Kessel, B. 11, 2112).

Myrtle wax. [49°]. Got by boiling the berries of *Myrica cerifera* of North America with water (Moore, J. 1862, 506). Consists of palmitic and some lauric acid and (20 p.c.) of palmitin.

Optum wax. Contains ceryl cerotate and ceryl palmitate (Hesse, B. 3, 637).

Tobacco wax. Contains $C_{26}H_{52}O_2$ [63°], insol. cold alcohol, sol. ether and a small quantity of $C_{26}H_{52}O_2$ [64.5°], sl. sol. cold ether (Kissling, B. 16, 2433).

Coca leaf wax (Hesse, A. 271, 214). The wax from Trujillo coca is palmityl-(β)-amyrin $C_{25}H_{50}O_2$ [75°] [α_D = 54.5°]. On saponification it yields palmitic acid and (β)-amyrin $C_{25}H_{50}O$ [196°] [α_D = 94.2°, which yields an acetyl derivative [236°] and a benzoyl derivative [228°]. The wax from the broad-leaved coca of Peru and Bolivia melts at 70°; contains palmityl-(β)-amyrin and a ketone, (β)-cerotinone $C_{25}H_{50}O$ [66°], m. sol. alcohol, ether, and ligroin. The wax from Java coca contains the same substances, and also some ceryl cerotate and ethers of myristic acid and of oxycerotic acid $C_{27}H_{54}O_2$ [82°], which is v. e. sol. hot alcohol and ligroin, v. sl. sol. ether, and is converted by Ac_2O at 100° into cerotic acid $C_{27}H_{54}O_2$ [70°].

WHEY-PROTEID v. MILK.

WINE OIL. *Light oil of wine*. An oil obtained in the preparation of ether by distilling alcohol with H_2SO_4 . The ether is shaken with milk of lime and fractionally distilled, the successive fractions being ether, alcohol, and wet alcohol. Light oil of wine (25 to 5 p.c. of the alcohol etherified) rises to the surface when the last fraction (90°–120°) is allowed to stand. When dried over $CaCl_2$ it has S.G. 17.5/20. It contains $C_{18}H_{36}$ (157°), $EtOC_8H_{17}$ (112°),

$Et.CO.C_8H_{17}$ (154°), and $CH_3.CO.C_8H_{17}$ (164°) (Hartwig, J. pr. [2] 23, 449).

Heavy oil of wine, which passes over when the temperature is raised after the preparation of ether, consists of $Et.SO_4$ mixed with olefines (Claesson, J. pr. [2] 19, 259; Serullas, A. Ch. [2] 89, 152).

WINTERGREEN OIL contains methyl o-crybenzoate.

WINTERENE $C_{15}H_{32}$. (260°–265°) S.G. 1.8934. [α_D] 11.2° at 16°. A dextrorotatory sesquiterpene obtained by distilling winterbark (from *Drymis Winter-Forster*) with water (Arata a. Canzoneri, G. 18, 527). Coloured green by Br in $CHCl_3$.

WOOD v. LIGNONE.

WOOD GUM v. XYLAN.

WOOD NAPHTHA v. METHYL ALCOHOL.

WOOD OIL. *Gurjun Balsam*. Flows from incisions in the stem of *Dipterocarpus costatus*. It contains an essential oil, which gives a splendid violet colour when its solution in CS_2 (20 pts.) is treated with a drop of a cold mixture of HNO_3 and H_2SO_4 . The same reaction is exhibited by the balsam itself, and also, in a more transient manner, by cod-liver oil and copaiba balsam (Flückiger, Ph. [3] 7, 2). The essential oil consists chiefly of a terpene (255°) (Werner, J. 1862, 461), which composes 65 p.c. of the balsam (Guibourt, J. 1876, 907). The resin contains a neutral substance, $C_{28}H_{56}O_2$, which crystallises from light petroleum in triclinic prisms [126°–130°]; it dissolves in conc. H_2SO_4 , and is reppd. from the resulting reddish solution by adding water. It is not affected by potash-fusion (Flückiger, Ar. Ph. [3] 12, 58). A substance $C_{28}H_{56}O_2$ [129°] is described by Brix (M. 2, 516) as ppd. by adding water to an alcoholic extract of wood oil. It is neutral and insol. alkalis, and yields a diacetyl derivative [75°]. It is perhaps identical with the compound $C_{28}H_{56}O_2$. Wood oil also contains gurjunic acid $C_{28}H_{54}O_2$ [220°], which crystallises from alcohol, distils with decomposition at 260°, and forms Ag_2A .

WOOD SPIRIT v. METHYL ALCOHOL.

WORMSEED OIL. *Oleum Cina*. Obtained by steam-distillation from wormseed, the flower-buds of *Artemisia Vahlana*, A. Sieberi, and *A. inculta* (Trommsdorff, Tr. N. J. 3, 812; Völkel, A. 38, 110; 87, 312; Hirzel, J. 1864, 591; 1855, 655; Kraut a. Wahlfors, A. 128, 293; Faust a. Homeyer, B. 7, 1429; Hell a. Ritter, B. 17, 2609; Wallach a. Brass, A. 225, 291). It consists chiefly of cineol $C_{15}H_{26}O$. Wormseed (*A. Gallica*) also contains betaine and choline (Jahns, B. 26, 1493).

WRIGHTINE $C_{11}H_{18}N$. [122°]. Occurs in the juice of *Wrightia antidysenterica* (Stenhouse, Ph. [2] 5, 493; Warnecke, B. 19, 60). Needles with bitter taste, sl. sol. water, v. sol. alcohol and ether. Conc. H_2SO_4 at 100° gives a dark-green colour, turned dark blue by adding water. Wrightine is probably identical with conessin (q. v.).

X

XANTHALINE $C_{12}H_{10}N_2O_4$. [206°]. Occurs in opium (T. a. H. Smith, *Ph.* [3] 28, 798). White crystalline powder, insol. water and alkalis, sl. sol. hot alcohol, m. sol. benzene, v. e. sol. chloroform. Weak base, forming yellow salts from which it is ppd. by hot water. Conc. H_2SO_4 forms a deep-orange solution, from which water ppts. the sulphate as yellow needles. Hot HNO_3 does not decompose it. Zinc and H_2SO_4 reduce it to hydroxanthaline $C_{12}H_{12}N_2O_4$, which forms white crystals [187°], nearly insol. water, v. sol. alcohol and benzene, and forms easily soluble crystalline salts. Hydroxanthaline is coloured deep-violet by H_2SO_4 (even free from HNO_3), the colour being destroyed by water, but reproduced by H_2SO_4 .— $B'H_3Cl_4$ aq.: yellow needles. Gives off all its acid at 150°.

XANTHAMIDE v. *Ethyl ether of (8)-Thio-carbamic acid*.

XANTHATES. The salts $RS.CS.OEt$ where R is a metal; v. **ETHYL DITHIOCARBONATE**.

XANTHIC ACID v. **ETHYL DITHIOCARBONATE**.

XANTHINE $C_5H_4N_4O_2$, i.e.

$NH.CH:C.NH > CO$. *Xanthic oxide*. Mol. w. $CO.NH.C=N$. 162. S. 007 in the cold; 08 at 100°. Occasionally found in urinary calculi (Marcet, *Essay on Calculi*, London, 1819; Liebig a. Wöhler, *A.* 26, 340; Lebon, *C. R.* 78, 47) and in urinary deposits (Bence Jones, *C. J.* 15, 78). Occurs in small quantity in the urine of man, in the pancreas, spleen, and liver of oxen, in the thymus gland of the calf, in muscle of mammalia and fishes (Scherer, *A.* 107, 314; 112, 257; Städeler, *A.* 111, 28; 116, 102; Dürr, *A.* 184, 46; Kossel, *H.* 6, 422), in some kinds of guano (Unger a. Phipson, *C. N.* 6, 16), and in yeast (Schindler, *H.* 18, 432). Occurs also in lupin seeds (Salomon, *J.* 1881, 1012; Schulze a. Barbieri, *J. pr.* [2] 27, 358), in pumpkin-seeds (E. Schulze, *J. pr.* [2] 32, 457), and in tea (Baginsky, *H.* 8, 396).

Formation.—1. By the action of nitrous acid on guanine (Strecker, *A.* 108, 141; 118, 151; 181, 121; Balke, *J. pr.* [2] 47, 542).—2. In small quantity by heating a mixture of $HOAc$ and aqueous HCl (Gautier, *Bl.* [2] 42, 141).

Preparation.—1. Separates as a crystalline powder when $NaNO_2$ (8 g.) is added slowly to a solution of guanine (10 g.) in H_2SO_4 (20 g.) and water (150 g.) at 75° (Fischer, *A.* 216, 309).—2. The aqueous extract of sprouting lupin seeds is evaporated, the residue treated with alcohol, and the alcoholic filtrate evaporated. The residue is dissolved in water and $AgNO_3$ and NH_3 added. The gelatinous pp. is disac'ed in hot HNO_3 (S.G. 1.1), which yields on cooling a crystalline compound of hypoxanthine and silver nitrate, and on adding NH_3 to the filtrate silver-xanthine is ppd. (S. a. B.).—3. Urine is ppd. with baryta-water; the filtrate is evaporated to a small bulk and boiled with cupric acetate. The pp. is dissolved in warm nitric acid and ppd. with $AgNO_3$; the pp. is crystallised from hot diluted HNO_3 , treated with ammoniacal $AgNO_3$, decomposed by H_2S , and the solution

evaporated.—4. A solution containing xanthine is treated with Fehling's solution and hydroxylamine hydrochloride, and the ppd. copper compound decomposed by H_2S . The xanthine may be further purified by preparing its lead salt and decomposing this with H_2S (Balke, *J. pr.* [2] 47, 552).

Properties.—Small scales (by evaporation) or powder composed of minute globules, nearly insol. cold water, insol. alcohol and ether. V. e. sol. $KOHAq$ and reppd. by CO_2 and other acids. Weak base. Does not form an acetate. A cold saturated aqueous solution of xanthin. gives white pps. with $HgCl_2$ and $AgNO_3$, and a yellowish-green, flocculent pp. with hot cupric acetate. An ammoniacal solution of xanthine is ppd. by $HgCl_2$, $ZnCl_2$, $CdCl_2$, and $AgNO_3$. Xanthine reduces ammoniacal cupric chloride (Drechsel, *B.* 25, 245'). Xanthine evaporated with nitric acid leaves a yellow residue turned orange by KOH (but not by NH_3), the colour becoming violet-red on warming. Solid xanthine added to a mixture of bleaching-powder and $NaOHAq$ on a watch-glass forms a dark-green spot, changing to brown and finally disappearing. Xanthine warmed with chlorine-water and a trace of HNO_3 , as long as gases escape, and then evaporated to dryness, yields a residue which is coloured rose-red by gaseous NH_3 (Weidel, *A.* 158, 365; Kossel, *H.* 6, 426).

Reactions.—1. Decomposed above 150°, giving off HCl , NH_3 , cyanogen, and CO_2 .—2. $KClO_4$ and $HClAq$ at 60° form urea and alloxan.—3. Conc. $HClAq$ at 230° forms glycocoll, formic acid, NH_3 , and CO_2 (E. Schmidt, *A.* 217, 311).—4. $NaOH$ (2 mols.) and $Pb(OAc)_2$ form a lead salt which, if dried and heated with MeI at 130°, yields theobromine (Fischer).—5. Slowly attacked by pure HNO_3 , the gas evolved consisting of nitrogen (1 vol.), CO_2 (4 vols.), and N_2O (11 vols.) (Franchimont, *R. T. C.* 6, 223).

Salts.— $B'HCl$. Nodular groups of silky needles.— $B'H_2SO_4$ aq. Scales, decomposed by water.— $B'BaH_2O_4$. Sl. sol. water.— $B'Cu_2O_4$. Formed by the action of Fehling's solution and hydroxylamine hydrochloride (Balke).— $B'Ag_2O$. Yellowish-white flocculent pp., got by adding $AgNO_3$ to an ammoniacal solution of xanthine. Blackens on boiling.— $NaC_5H_4N_4O_2$ aq. Minute needles.

Bromo-xanthine $C_5H_4BrN_4O_2$. Formed by heating xanthine with bromine at 100°, and also by the action of nitrous acid on bromoguanine (Fischer a. Reese, *A.* 221, 343). Crystalline powder, sol. conc. $HClAq$ and H_2SO_4 , but reppd. by water; sl. sol. hot water and hot alcohol; sol. alkalis.

Isoxanthine $C_5H_4N_4O_2$, i.e.

$NH.CO.C.NH > N$. Formed by reducing diazonitroso-methyl-uracil $C_5H_4N_4O_2$ with $SnCl_2$ and $HClAq$ (Behrend, *A.* 245, 223). Needles (containing $\frac{1}{2}aq$), sl. sol. hot water. Dissolves in Ac_2O without change. On evaporation with HNO_3 it leaves a residue coloured orange by

KOHAq. Yields $C_5H_7BrN_3O_2$ aq, crystallising from water in six-sided tables.

Pseudo-xanthine $C_5H_7N_3O_2$. A product of the action of H_2SO_4 (2 pts.) on uric acid (1 pt.) at 120° (Schultzen a. Filehne, *B.* 1, 150). Formed also by the action of nitrous acid on adenine (Kossel, *H.* 10, 258). Powder, sl. sol. water, HClAq, and NH_3 Aq, v. sol. KOHAq. Its aqueous solution is acid in reaction, and on evaporation with HNO_3 leaves a lemon-yellow residue, which is turned orange on warming with KOHAq.

The name **pseudo-xanthine** is also given by Gautier (*Bl.* [2] 48, 19) to a substance $C_5H_7N_3O$ occurring in muscular tissue. This is a yellow powder, which forms a very soluble hydrochloride. Its aqueous solution is ppd. by $HgCl_2$, $AgNO_3$, and ammoniacal $Pb(OAc)_2$, but not by $Pb(OAc)_2$. This pseudo-xanthine also gives an orange colour when the residue, after evaporation with HNO_3 , is treated with potash.

Paraxanthine $C_5H_7N_3O_2$ [c. 284°]. Occurs in human urine (Salomon, *B.* 16, 195; 18, 3406; *H.* 13, 187; Thudichum, *H.* 11, 415; Kossel, *H.* 13, 302). Silky needles or monoclinic tables, insol. alcohol and ether, sl. sol. cold water, v. sol. hot water. Sol. NH_3 Aq and HClAq. Poisonous, acting like caffeine and theobromine. $AgNO_3$ added to its solution in HNO_3 or NH_3 Aq gives a gelatinous or flocculent pp. Picric acid forms a yellow crystalline pp. when added to its solution in HClAq. Gives a red colour (like xanthine) when the residue after evaporation with chlorine-water is exposed to gaseous NH_3 . Does not give an orange colour when KOHAq is added to the residue after evaporation with HNO_3 . Conc. NaOHAq forms a crystalline salt. KOHAq does the same. A solution of paraxanthine is ppd. by $Cu(OAc)_2$, phosphotungstic acid, $HgCl_2$, and ammoniacal lead subacetate, but not by mercuric nitrate.

Heteroxanthine $C_5H_7N_3O_2$. Occurs in urine of men and dogs (Salomon, *B.* 18, 3407; *H.* 11, 412). Amorphous powder, v. sl. sol. cold water, sol. NH_3 Aq, insol. alcohol and ether. Its solution in HClAq is not ppd. by picric acid. $AgNO_3$, $HgCl_2$, $Cu(OAc)_2$, and ammoniacal lead subacetate give pps. When evaporated with chlorine-water and HNO_3 it leaves a residue which is coloured red by gaseous NH_3 , the colour changing to blue on addition of NaOHAq. NaOHAq forms a salt crystallising in tables, v. sol. water, sl. sol. NaOHAq. The hydrochloride forms sparingly soluble crystalline aggregates, which lose HCl on treatment with water.

Hypoxanthine v. vol. ii. p. 745.

XANTHINE $C_5H_4N_4O_2$. S. -0025 in the cold; +025 at 100° . Formed by heating ammonium thionurate at 200° (Finck, *A.* 132, 298). Got also by heating pseudo-uric acid with H_2SO_4 at 150° (Grimaux, *Bl.* [2] 31, 535). White powder, nearly insol. water, sol. NH_3 Aq, forming a solution with blue fluorescence. Its solution gives a white pp. with $HgCl_2$ and a yellow pp. with $AgNO_3$. Not attacked by HNO_3 . Sol. KOHAq and reppd. by CO_2 . Sol. conc. H_2SO_4 , forming a laminar sulphate, decomposed by water with separation of xanthine. —B'Ag₂O. Bulky yellow pp., got by pouring an ammoniacal solution of xanthine into excess of aqueous $AgNO_3$.

XANTHOCHELIDONIC ACID v. CHELIDONIC ACID.

XANTHOCREATININE v. CREATININE and LEUCOMAINES.

XANTHOGALLOL $C_{18}H_{11}Br_3O_4$ i.e.

$C_6H_4Br_2 \cdot O \begin{smallmatrix} \diagup O.C_6H_4Br_2 \\ \diagdown O.C_6H_4Br_2 \end{smallmatrix} O$ (?). [122°]. Formed by adding pyrogallol (1 pt.) to bromine (10 pts.), leaving the mixture to stand for two hours, and then shaking with water and heating (Stenhouse a. Groves, *C. J.* 28, 1; *A.* 177, 191; 179, 237; Theurer, *A.* 245, 334). Tri-bromo-pyrogallol is an intermediate body in its preparation. Yellow laminae (from CS₂ and ligroin), v. sol. ether and CS₂, m. sol. ligroin. Decomposed by boiling with water or alcohol. Very stable towards oxidising agents, even crystallising unaltered from conc. HNO_3 . Not reduced by sodium-amalgam or by zinc and dilute H_2SO_4 . Aniline in HOAc yields an anilide [205°], to which Theurer assigns the impossible formula $C_{18}H_{11}Br_{11}(NHPh)_3O_4$. *p*-Toluidine forms a corresponding *p*-toluide. Reacts with phenyl-hydrazine acetate.

Reactions. —1. NaOHAq forms hexa-bromobenzene dihydride $C_6H_2Br_6$ [139°], sl. sol. alcohol, which crystallises in prisms, while the mother-liquor contains a sodium salt of an acid $C_6H_2Br_6O_2$ [124°], which forms BaA', crystallising from dilute alcohol in large white plates (Theurer). By the action of dilute NaOHAq on xanthogallol, Hantzsch a. Schnitzer (*B.* 20, 2033) obtained $C_{18}H_{11}Br_{11}(OH)_3O_4$, which yields $Ba_3(C_{18}H_{11}Br_{11}O_4)_2$ and crystalline $C_{18}H_{11}Br_{11}Ac_2O_4$. 2. Na_2CO_3 Aq converts xanthogallol in the cold into $C_{18}H_{11}Br_{11}O_4$, crystallising from benzene in needles [72°] and prisms [131°], yielding the crystalline derivatives $C_{18}H_{11}Br_{11}O_4 \cdot 8NPhH_2$ and $C_{18}H_{11}Br_{11}O_4 \cdot 8NH_2 \cdot C_6H_5Me$. —3. HBr passed into a cooled solution of xanthogallol in MeOH forms $C_{18}H_{11}Br_{11}O_4(OMe)_6$, crystallising from MeOH in prisms [113°], and converted by boiling dilute NaOHAq into an acid $C_6H_2Br_6O_4(OMe)_2$ [105°], and by MeOH and hydrochloric acid into $C_6HBr_2Cl(OMe)_2$ [77°]. The brominated acid $C_6H_2Br_6O_4(OMe)_2$ reacts with aniline, forming crystalline $C_6H_2Br_6O_4(OMe)_2 \cdot NH_2Ph$. Conc. H_2SO_4 converts $C_6H_2Br_6O_4(OMe)_2$ into $C_6H_2Br_6O_4$ [65°]. —4. Hydrochloric acid gas passed into a cooled solution of xanthogallol in MeOH forms $C_{18}H_{11}Br_{11}Cl_3O_4(OMe)_6$ [86°], which is insol. water, v. sol. alcohol, does not react with aniline, and is decomposed by dilute alkalis. —5. HCl passed into an alcoholic solution of xanthogallol forms $C_{18}H_{11}Br_{11}Cl_3O_4(OEt)_6$, crystallising from alcohol in colourless prisms [75°], converted by NaOHAq into a product [92°]. $C_{18}H_{11}Br_{11}Cl_3O_4$ [104°] is a bye-product in the action of alcohol and HCl on xanthogallol. It forms large yellow crystals, v. sol. alcohol.

XANTHOGENIC ACID v. ETHYL DITHIOCARBONATE.

XANTHOMETHYLIC ACID v. METHYL THIOCARBONATES.

XANTHONE is DIPHENYLENE KETONE OXIDE.

XANTHOPURPURIN is *m*-DI-OXY-ANTHRAQUINONE.

XANTHQUINIC ACID v. OXY-QUINOLINE CARBOXYLIC ACID.

XANTHORHAMNIN $C_{16}H_{10}O_2$ (?). Obtained from Persian berries (the fruit of *Rhamnus infectoria*) by extracting with three times their

weight of 85 p.c. alcohol; the yield being 12 p.c. (Lieberrmann a. Hörmann, *B.* 11, 962, 1618; *A.* 196, 807; cf. Kane, *P. M.* [3] 23, 8; Gellatly, *N. E. P. J.* 7, 252; *C. N.* 8, 196; Hlasiwetz, *A.* 111, 108; Bolley, *A.* 115, 55; *C. J.* 13, 328; Stein, *Z.* [2] 5, 183, 568; Behrend, *B.* 11, 1353). Yellow needles (containing 2 aq), v. sol. water and alcohol, insol. ether. Has little tinctorial power. Reduces Fehling's solution and ammoniacal AgNO_3 , forming a mirror. FeCl_3 gives a dark-brown pp. Ppd. by ammoniacal lead acetate. Boiling dilute H_2SO_4 splits it up into rhamnetin (2 mols.) and isodulcitol (4 mols.).

Salts.— $\text{C}_{16}\text{H}_{12}\text{O}_4\text{K}_2$. Yellow powder, v. e. sol. water.— $\text{Pb}_2\text{A}^{\text{iv}}$. Yellow pp.

Acetyl derivatives $\text{C}_{18}\text{H}_{14}\text{Ac}_2\text{O}_8$ (Schützenberger, *Z.* [2] 4, 668).— $\text{C}_{18}\text{H}_{14}\text{Ac}_2\text{O}_8$. Powder, v. e. sol. alcohol (Lieberrmann a. Bergami, *B.* 20, 2245).

XANTHOROCELIN v. PICRO-ROCELIN.

XANTHORRHOEA RESIN is ACAROID RESIN.

XANTHOXYLIN $\text{C}_{16}\text{H}_{12}\text{O}_4$. [80°]. Occurs, together with xanthoxylene $\text{C}_{16}\text{H}_{16}$ (162°) in the essential oil from japan-pepper (*Xanthoxylon piperitum*) (Stenhouse, *Ph.* [2] 13, 423; 17, 19; *A.* 104, 237). Silky monoclinic crystals, insol. water, v. sol. alcohol and ether. Its alcoholic solution is not ppd. by AgNO_3 or lead acetate, even on addition of NH_4Aq .

XENYLAMINE v. *p*-AMIDO-DIPHENYL.

XENYLENE-DIAMINE v. *p-p*-DI-AMIDO-DIPHENYL.

XERONIC ACID v. DI-ETHYL-MALEIC ACID.

XYLAN $\text{C}_6\text{H}_{10}\text{O}_5$. *Tree gum. Wood gum.* S. 2 at 100°. [α_D] = -69.6° (Tollens); -84° (Thomsen). Obtained from the bark of trees (T. Thomsen, *J. pr.* [2] 19, 146; Poumarède a. Figuier, *A.* 64, 388). Obtained, to the extent of 1.73 p.c., by extracting jute with dilute (5 p.c.) NaOHAq ; and got also by extracting beech-wood or pine-wood sawdust with 5 p.c. NaOHAq (Tollens, *A.* 254, 307, 320, 324, 326; *Bl.* [3] 1, 1102; Winterstein, *H.* 17, 381). Obtained also by extracting wheat-straw, first with 2 p.c. NH_4Aq , and then with 5 p.c. NaOHAq (Tollens, *A.* 260, 291). The alkaline extract is ppd. with alcohol and HCl .

Properties.—Porous mass, insol. cold, sol. hot, water; sol. NaOHAq . The hot aqueous solution becomes opalescent on cooling. Insol. alcohol, but the aqueous solution is not ppd. by alcohol unless an acid or the salt of an alkali is added. Insol. NH_4Aq , lime- and baryta-water. Its aqueous solution is laevorotatory. Gives furaldehyde when distilled with H_2SO_4 or HCl , and xylose when boiled with dilute H_2SO_4 . Gives no colour with iodine. HNO_3 oxidises xylan to saccharic acid, but gives no mucic acid.

o-XYLENE C_8H_{10} , i.e. $\text{C}_6\text{H}_4\text{Me}_2$ [1:2]. *Dimethyl-benzene*. Mol. w. 106. [-28°] (Colson, *A. Ch.* [6] 6, 128). (142°). S.G. $\frac{3}{4}$ 8932 (Pinette, *A.* 243, 50); $\frac{24}{25}$ 876 (Gladstone, *C. J.* 59, 290). μ_D 1.4928, μ_H 1.5328. C.E. (0°-10°) 00098. S.V. 139.9 (Schiff); 137.6 (Pinette). H.C. 1,084,274 [C_2O_2 = 94,000; H_2O = 69,000] (Stohmann, *J. pr.* [2] 35, 41). M.M. 18.81 (Schönrock, *Z. F. C.* 11, 758. **Critical temperature:** 358° (Altschul, *Z. P. C.* 11, 590). Occurs in coal-tar. The S.G. of crude xylene varies between 857 and 866; it contains 70 to 87 p.c. *m*-xylene, 8 to 10 p.c. *p*-xylene, 2 to 15 p.c.

o-xylene, and 8 to 10 p.c. fatty hydrocarbons (Levinstein, *B.* 17, 444; cf. Fittig, *A.* 148, 10). If 100 c.c. of the mixture are boiled for 45 minutes with 40 c.c. of HNO_3 (S.G. 1.42) diluted with 60 c.c. of water, the *p*- and *o*-xylene are oxidised, leaving the *m*-xylene and fatty hydrocarbons. If the residual hydrocarbons, after washing with NaOHAq followed by steam distillation, be shaken for 80 minutes with 1½ volumes of H_2SO_4 , the *m*-xylene will be sulphonated and dissolved, while the fatty hydrocarbons remain. If 100 c.c. of crude xylene be shaken with 120 c.c. of H_2SO_4 , the *o*- and *m*-xylene dissolve, leaving the *p*-xylene and fatty hydrocarbons. On crystallising the sodium salts of the dissolved sulphonic acids, sodium *o*-xylene sulphonate separates first, and may be converted into *o*-xylene by heating in a sealed tube with HClAq at 190° (Jacobsen, *B.* 10, 1009), or by heating with diluted sulphuric acid. Nölting, Witt, and Forst. (*B.* 18, 2668) found 25 p.c. of *p*-xylene in commercial xylene. According to Nölting and Palmer (*B.* 24, 1955), crude xylene may contain 10 p.c. of ethyl-benzene. When a mixture of *o*-xylene and ethyl-benzene is treated with Br (20 pts.) and I, tetra-bromo-xylene is formed, together with a less highly brominated ethyl-benzene (Crafts, *C. R.* 114, 1110).

Formation.—1. By distilling its carboxylic acids with lime.—2. From *o*-bromo-toluene, MeI, and Na (Jannasch a. Hübner, *A.* 170, 117; Reymann, *Bl.* [2] 26, 532).—3. By heating cantharidin with P_2S_5 (Piccard, *B.* 12, 580).—4. By passing MeI through a mixture of toluene and AlCl_3 at 85° (Jacobsen, *B.* 14, 2628).

Properties.—Oil, solidifying in a freezing-mixture at -28°. Unlike *m*- and *p*-xylene it does not yield a solid nitro-derivative with a cold mixture of H_2SO_4 and HNO_3 . It is completely oxidised by chromic acid mixture.

Reactions.—1. Dilute HNO_3 forms *o*-toluic acid.—2. Boiling aqueous KMnO_4 oxidises it to phthalic acid.—3. PCl_5 at 200° reacts, forming $\text{C}_6\text{H}_4(\text{COCl})_2$ (Colson a. Gautier, *Bl.* [2] 45, 507).—4. *Bromine* in the dark forms bromo-*o*-xylene $\text{C}_6\text{H}_4\text{MeBr}$ [1:2:4]. In direct sunshine the products are $\text{C}_6\text{H}_4\text{Me.CH}_2\text{Br}$ and $\text{C}_6\text{H}_4(\text{CH}_2\text{Br})_2$ (Sohramm, *B.* 18, 1278).—5. AlCl_3 and gaseous HCl at 100° yield benzene, *m*- and a little *p*-xylene, ψ -cumene and mesitylene (Hesse a. Töhl, *A.* 270, 168).

m-Xylene $\text{C}_8\text{H}_{10}\text{Me}_2$ [1:3]. V.D. 8.68 (calc. 8.67) (Schiff, *A.* 220, 92). (139°). S.G. $\frac{3}{4}$ 8812 (Pinette, *A.* 243, 50); $\frac{12}{13}$ 8715 (S.); $\frac{24}{25}$ 8655 (Brühl, *A.* 235, 13); $\frac{22}{25}$ 864 (Gladstone, *C. J.* 59, 290). C.E. (0°-10°) 00096. μ 1.495 (B.) μ_D 1.4876, μ_H 1.5277. S.V. 139.8. H.C. 1,084,168 (Stohmann, *J. pr.* [2] 35, 41). M.M. 12.73 at 20°-30° (Schönrock, *Z. P. C.* 11, 758). **Critical temperature:** 346° (A.). Occurs in coal-tar (v. *o*-Xylene).

Formation.—1. From *m*-iodo-toluene, MeI, and Na (Wroblewsky, *A.* 192, 200).—2. From (1,3,4)-xylylidine and amyl nitrite (Staedel a. Holz, *B.* 18, 2919).—3. From toluene, MeCl, and AlCl_3 (Friedel a. Crafts, *A. Ch.* [6] 1, 461; Ador a. Billiet, *B.* 11, 1627).—4. By distilling mesitylenic and xylylic acids with lime (Fittig, *A.* 148, 10; 156, 286).

Properties.—Liquid. Not attacked by dilute HNO_3 . Conc. HNO_3 on warming forms tri-nitro-xylene $[\text{176}^\circ]$, sl. sol. alcohol.

Reactions.—1. Oxidised by chromic acid mixture to isophthalic acid.—2. PCl_5 at 200° forms a hexachloride (Colson a. Gautier, *Bl.* [2] 45, 508).—3. Bromine in the dark forms $\text{C}_8\text{H}_7\text{Me}_2\text{Br}$ [1:3:4], while in direct sunshine $\text{C}_8\text{H}_7\text{Me}(\text{CH}_2\text{Br})$ and $\text{C}_8\text{H}_7(\text{CH}_2\text{Br})_2$ are produced (Schramm, *Z.* 18, 1277; *M.* 8, 805).—4. AlCl_3 and gaseous HCl at 100° form benzene, mesitylene, and some *p*-xylene and ψ -cumene (Heise a. Töhl, *A.* 270, 168). On boiling with AlCl_3 the products are benzene, toluene, a little *p*-xylene, ψ -cumene, mesitylene, and durene (Anschtütz, *A.* 235, 182).—5. On heating with MeI and I at 250° it yields ψ -cumene, mesitylene, and $\text{C}_{10}\text{H}_{14}$ (Rayman a. Preis, *A.* 223, 320).—6. Ethyl-malonyl chloride at 60° in presence of AlCl_3 forms the ketone $\text{C}_{13}\text{H}_{14}\text{O}_2$ $[\text{63}^\circ]$ (Béhal a. Auger, *Bl.* [3] 8, 122).—7. Benzoyl peroxide forms dixylylene $\text{C}_{16}\text{H}_{18}$ (265°), S.G. 22.9984 (Lippmann, *M.* 7, 528).—8. CrO_2Cl_2 added to its solution in CS_2 ppts. chocolate brown $\text{C}_8\text{H}_7\text{Me}_2\text{CrO}_2\text{Cl}_2$, which is converted by water into *m*-toluic aldehyde and at 200° yields $\text{C}_8\text{H}_7\text{Me}.\text{CH}(\text{CrO}_2\text{Cl})_2$ (Étard, *A. Ch.* [5] 22, 244).—9. CH_2Cl_2 and AlCl_3 form tetramethyl-anthracene $[\text{163}^\circ]$ (Friedel a. Crafts, *A. Ch.* [6] 11, 268).—10. PHI forms C_8H_7 , on heating (Baeyer, *Z.* [2] 4, 455). HIAq and P at 280° form *m*-xylene hexahydride.

p-Xylene $\text{C}_8\text{H}_7\text{Me}_2$ [1:4]. $[\text{13}^\circ]$ (Beissert, *B.* 23, 2242); $[\text{15}^\circ]$ (Jannasch). (138°). S.G. 2.8801 (*P.*); 2.860 (Gladstone, *C. J.* 59, 290). C.E. (0°–10°) .00098 (Pinette, *A.* 243, 51). μ_d 1.4854. μ_H 1.5253. S.V. 140 (Schiff). H.C. 1,084,274 (Stohmann, *J. pr.* [2] 35, 41). M.M. 12–79 at 20°–30° (Schönrock, *Z. P. C.* 11, 753). Critical temperature: 344° . Occurs in coal-tar (*v. supra*) and in Galician petroleum (Pawlewski, *B.* 18, 1915). Formed by the action of MeI and sodium on *p*-bromo-toluene (Fittig, *A.* 136, 303; Jannasch, *A.* 171, 79) and on *p*-di-bromo-benzene (V. Meyer, *B.* 3, 753). Monoclinic prisms; $a:b:c = 2:32:1:2:34$; $\beta = 69:5^\circ$ (Baeyer, *A.* 245, 141).

Reactions.—1. Dilute HNO_3 forms *p*-toluic acid.—2. Chromic acid mixture yields terephthalic acid.—3. PCl_5 at 190° gives $\text{C}_8\text{H}_7(\text{CH}_2\text{Cl})_2$ and at 200° $\text{C}_8\text{H}_7(\text{CCl}_2)_2$ (Colson a. Gautier, *Bl.* [2] 45, 6, 507).—4. Bromine in the dark forms $\text{C}_8\text{H}_7\text{BrMe}_2$, while in direct sunshine the products are $\text{C}_8\text{H}_7\text{Me}.\text{CH}_2\text{Br}$ and $\text{C}_8\text{H}_7(\text{CH}_2\text{Br})_2$ (Schramm, *B.* 18, 1276).—5. AlCl_3 and HCl at 100° act in the same way as with *o*-xylene.

References.—BROMO-, BROMO-NITRO-, CHLORO-, DIHYDRO-NITRO-, DI-iodo-, NITRO-, and OXY-XYLENES.

XYLENE-AZO- compounds *v.* Azo-compounds.

XYLENE CARBOXYLIC ACID *v.* Di-methyl-benzoic acid and Mesitylenic acid.

***m*-XYLENE DICARBOXYLIC ACID** $\text{C}_{10}\text{H}_{10}\text{O}_4$, i.e. $\text{C}_8\text{H}_7\text{Me}_2(\text{CO}_2\text{H})_2$ [1:3:4:6]. Dimethyl-isophthalic acid.

(a)-Cumidic acid. Mol. w. 194. [above 320°]. Formed by heating di-bromo-*m*-xylene dissolved in ether under pressure with ClCO_2Et and sodium-amalgam. Formed also, together with (β)-cumidic acid, by oxidation of durene with dilute HNO_3 or of durylic acid with KMnO_4 (Schnapauff,

B. 19, 2508). Minute prisms (from water) or plates (by sublimation).— BaA'' 1:4:4:4: crystals, *v.* sol. water. Yields *m*-xylene on distilling with lime.

Methylether $\text{Me}_2\text{A}''$. $[\text{76}^\circ]$. Crystals.

m-Xylene dicarboxylic acid

$\text{C}_8\text{H}_7\text{Me}_2(\text{CO}_2\text{H})_2$ [1:3:4:5]. Dimethyl-phthalic acid. Isocumidic acid. $[\text{280}^\circ]$. Formed by oxidation of (β)- and (γ)-isodurylic acid (Jacobsen, *B.* 15, 1857). Small crystals. May be sublimed. Yields *m*-xylene on distillation with lime. The Ca salt crystallises in small plates. The Ba salt is amorphous.

p-Xylene dicarboxylic acid

$\text{C}_8\text{H}_7\text{Me}_2(\text{CO}_2\text{H})_2$ [1:4:2:5]. Di-methyl-terephthalic acid. (β)-Cumidic acid. Formed, together with (α)-cumidic acid, by oxidation of *s*-durene with dilute HNO_3 or of durylic acid with KMnO_4 (*S.*). Minute six-sided prisms (from alcohol). Sublimes in small plates without melting. Nearly insol. hot water. Yields *p*-xylene on distilling with lime.— BaA'' 2:3:4:4: tables, *v.* sol. water.

Methylether $\text{Me}_2\text{A}''$. $[\text{114}^\circ]$. (c. 297° cor.).

Xylene dicarboxylic acid

$\text{C}_8\text{H}_7\text{Me}(\text{CO}_2\text{H})\text{CH}_2\text{CO}_2\text{H}$ [3:2:1]. $[\text{178}^\circ]$. Formed by oxidation of $\text{C}_8\text{H}_7\text{Me}(\text{CO}_2\text{Et})\text{CH}_2\text{CO}_2\text{H}$ (Béhal a. Auger, *C. R.* 109, 972). Gives off CO_2 on fusion.

Xylene di-*o*-carboxylic acid *v.* PHENYLENE-DIACETIC ACID.

Reference.—OXY-XYLENE CARBOXYLIC ACID.

XYLENE GLYCOL *v.* Di-oxy-xylene.

o-XYLENE DIHYDRIDE *v.* CANTHARENE.

m-Xylene dihydride C_8H_{12} . (133°). S.G. 22.828. V.D. 3.74 (calc. 3.88). μ_D 1.4675. Formed, together with a polymeride $\text{C}_{10}\text{H}_{14}$ (280° – 285°) S.G. 22.832, by heating the ketone $\text{C}_8\text{H}_7\text{O}$ with ZnCl_2 . The ketone itself is obtained by distilling the anhydride $\text{C}_{10}\text{H}_8\text{O}$, which is got by the action of Ac_2O on cineolic acid, formed by oxidation of eucalyptol (Wallach, *A.* 258, 827). Liquid, smelling like xylene. Yields on nitration $\text{C}_8\text{H}_7\text{Me}_2(\text{NO}_2)_2$ [1:3:4].

p-Xylene dihydride $\text{CMe} \begin{smallmatrix} \text{CH}.\text{CH}_2 \\ \text{CH}_2.\text{CH} \end{smallmatrix} \text{CMe}$.

(134°) at 720 mm. Formed by heating di-methyl-quinite dibromide $\text{C}_8\text{H}_7\text{Br}_2$ with quinoline (Baeyer, *B.* 25, 2122). Smells like turpentine. Forms a crystalline compound with HBr .

m-Xylene tetrahydride $\text{C}_8\text{H}_{10}\text{Me}_2$. (119°). S.G. 2.814; d_4 .794.

Formation.—1. By heating oxycamphoric anhydride $\text{C}_{10}\text{H}_{14}\text{O}_4$ with water at 180° or with HI at 150° (Wreden, *A.* 163, 336).—2. By heating camphoric acid with syrupy phosphoric acid at 200° .—3. By distilling camphoric acid with ZnCl_2 (Ballo, *A.* 197, 322).—4. By heating camphoric acid with HIAq at 200° (Wreden, *A.* 187, 171).

Properties.—Oil. Oxidised by chromic acid mixture to acetic, isotoluic, isophthalic, and terephthalic acids. HNO_3 forms tri-nitro-*m*-xylene.

Xylene tetrahydride C_8H_{14} . (181°). S.G. 22.816. Occurs among the products of the distillation of colophony (Renard, *A. Ch.* [6] 1, 236). Slightly dextrorotatory liquid. Yields oily di- and tri-bromo-derivatives. Sulphuric acid forms an oily polymeride $\text{C}_{10}\text{H}_{18}$, which is oxidised by fuming HNO_3 to succinic and oxalic acids. Absorbs oxygen. Does not reduce

ammoniacal AgNO_3 . In ethereal solution it combines with Br, forming $\text{C}_8\text{H}_8\text{Br}_2$.

***m*-Xylene tetrahydride (?)** C_8H_{10} . (120°). *Octonaphthylene*. Formed by the action of moist Ag_2O on $\text{C}_8\text{H}_8\text{I}_2$, which is got by the action of CaI_2 at 60° on $\text{C}_8\text{H}_8\text{I}_2\text{Cl}$ (175°), a product of the chlorination of octonaphthene (Jakowkin, *J. R.* 16, ii. 294). Oil, smelling like turpentine. Combines with Br (2 atoms). An isomeric octonaphthylene (123°–129°) is got by distilling $\text{C}_8\text{H}_8\text{I}_2\text{Cl}$ obtained by chlorination of iso-octonaphthene (Putochin, *J. R.* 16, ii. 295).

***m*-Xylene hexahydride** C_8H_{12} , i.e. $\text{C}_8\text{H}_{10}\text{Me}_2$ [1:3]. *Octonaphthene*. (118°). S.G. $\frac{1}{4}$ 7814 (Lossen, *A.* 225, 110); $\frac{1}{2}$ 7706 (A.). C.E. (0°–26°) 001072. V.D. 3.87. S.V. 164.8. $\mu_D = 1.419$ at 22° (Wallach, *B.* 25, 923). Occurs in Baku petroleum (Beilstein a. Kurbatoff, *B.* 13, 1820; Markownikoff a. Spady, *B.* 20, 1850), and among the products of the distillation of colophony (Renard, *A. Ch.* [6] 1, 229). Formed by heating heptanaphthene carboxylic acid with HIAg and P (Aschan, *B.* 24, 2718). Prepared by heating bromo-camphor with ZnCl_2 or *m*-xylene with HIAg at 200° (Wreden, *A.* 187, 157). Liquid. Not oxidised by aqueous KMnO_4 . H_2SO_4 and HNO_3 form tri-nitro-*m*-xylene. Sulphur at 220° forms *m*-xylene.

Isomeride C_8H_{10} . *Iso-octonaphthene*. (122°). S.G. $\frac{1}{4}$ 7767 $\frac{17.5}{0}$ 7637. Occurs in Caucasian petroleum (Putochin, *J. R.* 16, ii. 295). Liquid.

***p*-Xylene hexahydride** $\text{C}_8\text{H}_{10}\text{Me}_2$ [1:4]. (138° cor.). V.D. 4.01 (obs.). S.G. $\frac{1}{4}$ 7956. Formed by heating bromo-camphor with ZnCl_2 (R. Schiff, *B.* 13, 1407; *G.* 10, 320). Liquid, yielding tri-nitro-*p*-xylene [127°] on nitration.

***m*-XYLENE PHOSPHINIC ACID**

Chloride $\text{C}_8\text{H}_7\text{Me}_2\text{PCl}_2$ [1:3:4]. (257°). Got from mercuric diethyl $\text{Hg}(\text{C}_2\text{H}_5)_2$ [4:1:3], and PCl_3 at 235° (Weller, *B.* 20, 1720). Liquid, converted by water into the acid $\text{C}_8\text{H}_7\text{Me}_2\text{P}(\text{OH})_2$. Chlorine forms the compound $\text{C}_8\text{H}_7\text{Me}_2\text{PCl}_3$, which is converted by water into $\text{C}_8\text{H}_7\text{Me}_2\text{P}(\text{OH})_3$ [194°].

***m*-Xylene-phosphinic acid** $\text{C}_8\text{H}_7\text{Me}_2\text{P}(\text{OH})_2$ [98°] (Michaelis, *A.* 212, 237). Formed by the action of water on the chloride. Needles (from alcohol). Probably a mixture.

Chloride $\text{C}_8\text{H}_7\text{Me}_2\text{PCl}_2$ (256°). S.G. $\frac{1}{4}$ 124. Formed from *m*-xylene, PCl_3 , and AlCl_3 (Weller, *B.* 20, 1720). It is a mixture of the preceding body and the 1,3,5 isomeride. Readily absorbs chlorine, forming $\text{C}_8\text{H}_7\text{Me}_2\text{PCl}_3$, whence SO_2 forms $\text{C}_8\text{H}_7\text{Me}_2\text{POCl}_2$ (280°–300°).

***p*-Xylene phosphinic acid** $\text{C}_8\text{H}_7\text{Me}_2\text{P}(\text{OH})_2$. *p*-Xylene phosphinous acid. Formed by treating the chloride with hot water (Weller, *B.* 21, 1494). Crystallises with difficulty.

Chloride $\text{C}_8\text{H}_7\text{Me}_2\text{PCl}_2$. [–30°]. (254°). S.G. $\frac{1}{4}$ 125. Formed by heating *p*-xylene (150 g.) with AlCl_3 (30 g.) and PCl_3 (200 g.) for 86 hours with inverted condenser (Michaelis a. Paneck, *A.* 212, 236). Strongly refracting liquid.

***m*-XYLENE *i*-PHOSPHONIC ACID**

***C*-Xylene *i*-phosphonic acid** $\text{C}_8\text{H}_7\text{Me}_2\text{PO}(\text{OH})_2$. *m*-Xylene (α)-*i*-phosphonic acid. [194°]. S. 1.5 at 20°; 6.9 at 100°. Formed by boiling the chloride $\text{C}_8\text{H}_7\text{Me}_2\text{PCl}_2$ (*v. supra*) with water (Weller, *B.* 20, 1721). Needles, v. s. sol. alcohol. Decomposed into *m*-xylene

and phosphoric acid on heating with alkalis. Br added to dilute solutions forms bromo- and di-bromo-*m*-xylene. Yields two nitro-derivatives [182°] and [100°].

Salts.— BaA'' aq. Plates. — $\text{CdH}_2\text{A''}$ aq. Plates, more sol. cold than hot water. — $\text{NiH}_2\text{A''}$ aq.— $\text{Ag}_2\text{A''}$: white pp.

***m*-Xylene *s*-phosphonic acid** $\text{C}_8\text{H}_7\text{Me}_2\text{PO}(\text{OH})_2$. *m*-Xylene (β)-*s*-phosphinic acid. [161°]. S. 1.8 at 15°; 117.3 at 100°. Prepared by boiling with water the mixture of chlorides $\text{C}_8\text{H}_7\text{Me}_2\text{POCl}_2$ (280°–300°) which is got by the action of SO_2 on the mixture of tetrachlorides $\text{C}_8\text{H}_7\text{Me}_2\text{PCl}_4$ formed by combination of chlorine with the mixture of chlorides $\text{C}_8\text{H}_7\text{Me}_2\text{PCl}_3$ obtained by heating *m*-xylene with PCl_3 and AlCl_3 (W.). Plates or needles, v. s. alcohol and ether. Decomposed by alkalis into *m*-xylene and phosphoric acid.

***p*-Xylene phosphonic acid** $\text{C}_8\text{H}_7\text{Me}_2\text{PO}(\text{OH})_2$. [180°]. Formed by the action of PCl_3 on $\text{C}_8\text{H}_7\text{Me}_2\text{PCl}_3$ [c. 60°] which is got by passing Cl through the product of the action of PCl_3 on *p*-xylene in presence of AlCl_3 (Weller, *B.* 21, 1494). Needles, m. sol. water, v. sol. alcohol, s. ether. Conc. HNO_3 forms the compound $\text{C}_8\text{H}_7(\text{NO}_2)_3\text{PO}(\text{OH})_2$ [224°]. KMnO_4 yields $\text{C}_8\text{H}_7\text{Me}(\text{CO}_2\text{H})_2\text{PO}_2\text{H}_2$ [278°].

Salts.— KHA'' .— BaA'' . Pearly plates, more sol. cold than hot water.

Chloride $\text{C}_8\text{H}_7\text{Me}_2\text{POCl}_2$. (281°). S.G. $\frac{1}{4}$ 131. Oil. Formed by the action of SO_2 on $\text{C}_8\text{H}_7\text{Me}_2\text{PCl}_3$.

Reference.—NITRO-XYLENE PHOSPHONIC ACID.

XYLENE PHTHALOYLIC ACID v. PHENYL XYLYL KETONE CARBOXYLIC ACID.

***o*-XYLENE SULPHINIC ACID** $\text{C}_8\text{H}_7\text{SO}_2$, i.e. $\text{C}_8\text{H}_7\text{Me}_2\text{SO}_2\text{H}$ [1:2:4]. [83°]. Formed by the action of zinc-dust on *o*-xylene sulphochloride (Jacobsen, *B.* 10, 1011). Plates (from water).

***m*-Xylene sulphinic acid** $\text{C}_8\text{H}_7\text{Me}_2(\text{SO}_2\text{H})$ [1:3:4]. [c. 50°]. Formed by reducing the sulphonic chloride $\text{C}_8\text{H}_7\text{Me}_2\text{SO}_2\text{Cl}$ (Jacobsen; cf. Lindoff a. Otto, *A.* 146, 233). Crystalline.

***p*-Xylene sulphinic acid** $\text{C}_8\text{H}_7\text{Me}_2(\text{SO}_2\text{H})$ [1:4:2]. [85°]. Groups of needles (Jacobsen, *B.* 11, 22).

***o*-XYLENE SULPHONIC ACID** $\text{C}_8\text{H}_7\text{SO}_3$, i.e. $\text{C}_8\text{H}_7\text{Me}_2(\text{SO}_3\text{H})$ [1:2:4]. Formed by warming *o*-xylene with H_2SO_4 (Jacobsen, *B.* 10, 1011; 11, 22). Tables (containing 2aq) (from dilute H_2SO_4).— NaA' 5aq.— BaA' 2aq. S. 5.8 at 0°; 33.6 at 100°.

Chloride $\text{C}_8\text{H}_7\text{Me}_2\text{SO}_2\text{Cl}$. [52°]. Prisms.

Amide $\text{C}_8\text{H}_7\text{Me}_2\text{SO}_2\text{NH}_2$. [144°]. Yields two acids $\text{C}_8\text{H}_7\text{Me}(\text{CO}_2\text{H})\text{SO}_2\text{NH}_2$ on oxidation by KMnO_4 .

***o*-Xylene *c*-sulphonic acid** $\text{C}_8\text{H}_7\text{Me}_2\text{SO}_3\text{H}$ [1:2:3]. Formed by the action of sodium-amalgam on $\text{C}_8\text{H}_7\text{Me}_2\text{Cl}(\text{SO}_2\text{H})$ [1:2:6:3] (Krüger, *B.* 18, 1760).

Amide $\text{C}_8\text{H}_7\text{Me}_2\text{SO}_2\text{NH}_2$. Granules.

***m*-Xylene *c*-sulphonic acid** $\text{C}_8\text{H}_7\text{Me}_2(\text{SO}_3\text{H})$ [1:3:2]. *m*-Xylene (β)-*sulphonic acid*. Formed, together with a larger quantity of the (1,3,4)-isomeride, by dissolving *m*-xylene in fuming H_2SO_4 (Jacobsen, *A.* 184, 188; *B.* 11, 18). It remains in the acid liquor after ppg. the (1,3,4)-isomeride by the proper quantity of water. Potash-fusion yields *p*-xylenol [74.5°] (Jacobsen, *B.* 21, 2828). Its K salt heated with sodium

formate forms an acid $C_6H_4O_2$ [99°].—KA'.—BaA'. minute needles.—CuA'. aq.

Chloride $C_6H_4Me_2SO_2Cl$. Oil.

Amide $C_6H_4Me_2SO_2NH_2$. [96°]. Needles.

m-Xylene sulphonic acid $C_6H_4Me_2(SO_3H)$ [1:3:4]. *m*-Xylene (α)-sulphonic acid. Formed as above. Long flat prisms (containing 2aq). Its K salt heated with sodium formate yields xylylic acid.—NaA'.—BaA'. Small plates.—ZnA'. 9aq.—CuA'. 6aq.

Chloride $C_6H_4Me_2SO_2Cl$. [34°].

Amide [137°]. Needles (from water).

BzCl at 160° forms $C_6H_4Me_2SO_2NHBz$ [151°] (Mahon, *Am.* 4, 194), which yields crystalline $Ca(C_6H_4NSO_2)_2$ aq and BaA'. sl. sol. water.

p-Xylene sulphonic acid $C_6H_4Me_2(SO_3H)$ [1:4:2]. Formed by sulphonating *p*-xylene (Beilschlein a. Wahlforss, *A.* 133, 38; Fittig a. Glinzer, *A.* 186, 305; Jacobsen, *B.* 10, 1009; 11, 22; Remsen a. Emerson, *Am.* 8, 265). Plates or prisms (containing 2aq). Oxidised by alkaline $KMnO_4$ to sulpho-terephthalic and two sulpho-p-toluic acids.—NaA'. aq. [148°]. Trimetric plates; *abc*: c = 1.077:1.1488 (Moody a. Nicholson, *C. J.* 57, 978).—KA'. aq.—BaA'. S. 2.27 at 0°; 5.53 at 100°.—CuA'. 8aq. Light-blue triclinic prisms.—ZnA'. 10aq.

Chloride $C_6H_4Me_2SO_2Cl$. [26°]. Prisms.

Amide [148°]. Needles, m. sol. hot water.

o-Xylene disulphonic acid $C_6H_4Me_2(SO_3H)_2$. Formed by heating (1,2,4)-xylene sulphonic acid with $ClSO_3H$ at 150° (Pfannenstill, *J. pr.* [2] 46, 155).—K₂A'. aq.—BaA'. 3aq.—PbA'. 3aq. Prisms.

Chloride $C_6H_4Me_2(SO_2Cl)_2$. [79°]. Prisms.

Amide $C_6H_4Me_2(SO_2NH_2)_2$. [239°].

m-Xylene disulphonic acid $C_6H_4Me_2(SO_3H)_2$ [1:3:4:2]. Formed by heating *m*-xylene with fuming H_2SO_4 at 150° (Wisohin, *B.* 23, 3113), and by heating (1,3,4)-xylene sulphonic acid with SO_3 at 150° (P.). Deliquescent needles, converted by potash-fusion into $C_6H_4Me_2(OH)_2$ [146°].—(NH₄)₂A'.—NaHA'. 3aq.—K₂A'. 2aq.—BaA'. 8aq. Needles, v. sol. water.—PbA'. 3aq.—CuA'. Gummy mass.

Ethyl ether Et.A'. Plates.

Chloride $C_6H_4Me_2(SO_2Cl)_2$. [129°]. Converted by PCl_5 at 180° (2,4,1,3)-di-chloro-xylene (220°).

Amide $C_6H_4N_2S_2O_4$. [249°]. Needles.

Oxidised by $KMnO_4$ to $C_6H_2(\begin{smallmatrix} \text{OO} \\ \diagup \diagdown \end{smallmatrix})NH_2$ [225°].

Ethylamide $C_6H_4Me_2(SO_2NHEt)_2$. [135°].

m-Xylene disulphonic acid $C_6H_4Me_2(SO_3H)_2$ [1:3:2:6?]. Formed in small quantity, together with the preceding isomeride, by heating (1,3,2)-xylene sulphonic acid with $ClSO_3H$ at 150° (Pfannenstill, *J. pr.* [2] 46, 154). Needles.

Chloride $C_6H_4Me_2(SO_2Cl)_2$. Oil.

Amide. [210°]. More sol. water than its isomeride.

p-Xylene disulphonic acid $C_6H_4Me_2(SO_3H)_2$ [1:4:2:6?]. Formed by heating (1,4,2) $C_6H_4Me_2(SO_2Cl)$ with fuming H_2SO_4 (Holmes, *Am.* 13, 372; Pfannenstill, *J. pr.* [2] 46, 156). Needles, v. e. sol. water.—BaA'. 3aq.—CaA'. 4aq.—MgA'. 7aq.—PbA'. 3aq.—Ag₂A'. aq.

Chloride $C_6H_4Me_2(SO_2Cl)_2$. [75°].

Amide $C_6H_4Me_2(SO_2NH_2)_2$. [295°].

References.—Bromo-, Bromo-nitro-, Nitro-, and Nitro-amido-, xylene sulphonic acid.

XYLENE THIOSULPHONIC ACID. *Xylyl ether* $C_6H_4SO_2S_2C_6H_5$. *Xylyl disulphide*. Formed by heating xylene sulphonic acid with water at 150°–160° (Otto a. Lindoff, *A.* 146, 239). Oil, v. sol. alcohol and ether.

XYLENIC ALCOHOL is TOLYL-CARBINOL.

XYLENIC DIBROMIDE v. Di-*o*-BROMOXYLENE.

XYLENIC GLYCOL v. Di-*o*-OXYXYLENE.

o-XYLENOL C_6H_4O i.e. $C_6H_4Me_2OH$ [1:2:4]. Mol. w. 122. [62°]. (225° i.V.). H.F.p. 61,566 (Stohmann, *J. pr.* [2] 34, 316). Obtained by potash-fusion from the sulphonic acid (Jacobsen, *B.* 11, 28), and by the diazo-reaction from (1,2,4)-xylydine (Jacobsen, *B.* 17, 161). Long needles (from water). $SiCl_4$ yields $Si(OC_6H_4)_2$, crystallising in prisms (350°–360° at 120 mm.) (Hertkorn, *B.* 18, 1891). Ammoniacal $ZnBr_2$ at 300° from xylydine and dixylylamine.— $NaOC_6H_5$. Flat needles, v. sl. sol. $NaOHAq$.

Benzoyl derivative [57°]. H.F. 77,768 (Stohmann, *J. pr.* [2] 36, 8).

o-Xylenol $C_6H_4Me_2(OH)$ [1:2:3]. [75°]. (218° i.V.). Occurs in coal-tar (Schulze, *B.* 20, 410). Formed by the action of nitrous acid on *o*-xylydine (Töhl, *B.* 18, 2562; Nölting a. Forel, *B.* 18, 2673). Slender needles. Its aqueous solution gives a blue colour with $FeCl_3$.

c-m-Xylenol $C_6H_4Me_2(OH)$ [1:3:2]. [49°]. Obtained from the crude xylydine, or by the action of HCl on *p*-oxy-mesitylenic acid (Nölting; Jacobsen, *B.* 21, 2829). *p*-Xylenol is got instead of *m*-xylenol by potash-fusion from (1,3,2)-xylene sulphonic acid (Jacobsen, *B.* 11, 26; 21, 2828).

m-Xylenol $C_6H_4Me_2(OH)$ [1:3:4]. [26°] (Jacobsen, *B.* 18, 3463); [28°] (Staedel a. Hölz, *B.* 18, 2919). (211.5° i.V.). S.G. $\frac{1}{4}$ 1.0362. H.F.p. 59,501 (Stohmann, *J. pr.* [2] 34, 316).

Formation.—1. From *m*-xylene sulphonic acid by potash-fusion (Jacobsen, *B.* 11, 24, 875; cf. Wroblewsky, *Bl.* [2] 10, 286; Wurtz, *J.* 1868, 459).—2. By heating oxy-mesitylenic acid with conc. $HClAq$ at 200° (Jacobsen, *B.* 11, 2059).—3. By reduction of nitro-*m*-xylene and treatment of the resulting xylydine with nitrous acid (Harmsen, *B.* 13, 1558; S. a. S.; Hodgkinson a. Limpach, *C. J.* 63, 104).

Properties.—Needles, v. sl. sol. water, miscible with alcohol and ether. Volatile with steam. $FeCl_3$ colours its aqueous solution blue and its alcoholic solution green, being changed to bright blue on dilution with water. Yields the corresponding xylydine and di-xylylamine when heated with $ZnBr_2$, ammonia, and NH_4Br at 315° (Müller, *B.* 20, 1041). Potash-fusion forms (4,1,3)-oxy-toluic acid. Yields oily $P(OC_6H_4)_3$ (Kreysler, *B.* 18, 1703). $SiCl_4$ forms $S(OC_6H_4)_2$ (455°) (Hertkorn, *B.* 18, 1890).

Salt.— $NaOC_6H_5$. V. sol. water and conc. $NaCHAq$ (unlike Na salts of other xylenols).

Methyl ether $MeOC_6H_4$ (192° i.V.) (J.); (186°) (S.). H.F.p. 46,336 (Stohmann, *J. pr.* [2] 35, 24).

Acetyl derivative C_6H_4OAc . (226° i.V.).

s-XYLYLOL $C_6H_4Me_2(OH)$ [1:3:5]. [64°] (T.); [68°] (N. a. F.) (220°). Occurs in coal-tar (Schulze, *B.* 20, 410). Formed by the action of nitrous acid on *s*-xylydine (Töhl, *B.* 18, 362; Nölting a. Forel, *B.* 18, 2679). Slender needles (from

water). Not coloured by FeCl_3 .— NaOC_2H_5 . Plates, sl. sol. NaOHAq .

p-Xylenol $\text{C}_6\text{H}_4\text{Me}_2(\text{OH})$ [1:4:2]. [74°5']. (211°5' i.v.). H.F.p. 61,862 (Stohmann, *J. pr.* [2] 84, 816). S.G. 21.971. Formed by potash-fusion from *m*- and from *p*-xylene sulphonic acid and from *oxy*-mesitylenic acid (Wurtz, *A.* 147, 873; Jacobsen, *B.* 11, 26). Formed also from *p*-xylydine by diazotisation followed by boiling with water (Nölting, Witt, a. Forel, *B.* 18, 2665). Long flat needles (from dilute alcohol). Volatile with steam. Its aqueous solution is not coloured by FeCl_3 .

Potash-fusion gives (3,4,1)-*oxy*-toluic and *oxy*-terephthalic acids. KNO_3 and HOAc yield a nitroso-derivative $\text{C}_6\text{H}_4\text{Me}_2(\text{OH})(\text{NO})$ [1:4:3:6] [163°], which is the oxim of *p*-xyloquinone (Olivieri, *G.* 12, 162; Goldschmidt a. Schmid, *B.* 18, 568).

Salt.— NaOC_2H_5 . Large plates, sl. sol. cold NaOHAq .

Methyl ether $\text{MeOC}_6\text{H}_4\text{Me}$. (194° i.v.). Oil.

Ethyl ether $\text{EtOC}_6\text{H}_4\text{Me}$. (199°) (S.); (205°) (N. W. a. F.). Oil. H.F.p. 54,150.

Acetyl derivative $\text{C}_6\text{H}_4\text{Me}_2\text{OAc}$. (237° i.v.). S.G. 1.0264. Oil, not solid at -20°.

Xylenol. (220°). Occurs in beechwood-tar (Marasse, *A.* 152, 75; Tiemann a. Mendelssohn, *B.* 10, 57). Oil. Yields $\text{C}_6\text{H}_4\text{OMe}$ (220°). On boiling with aqueous KMnO_4 , it yields an acid which is converted by potash-fusion into *u*-oxyisophthalic acid [300°].

References.—Bromo- and Nitro-XYLENOLS.

XYLENOLIC ACID *v.* OXY-DI-METHYL-BENZOIC ACID.

o-XYLENOL SULPHONIC ACID $\text{C}_6\text{H}_4(\text{OH})\text{SO}_3\text{H}$, *i.e.* $\text{C}_6\text{H}_4\text{Me}_2(\text{OH})\text{SO}_3\text{H}$. Formed by sulphonation of (1,2,4)-xylenol (Jacobsen, *B.* 11, 24). FeCl_3 gives a violet colour in neutral solutions.— NaA' . Slender prisms or small laminae.— BaA' . Nodular groups of minute laminae, sl. sol. cold water.

m-Xylenol (a)-sulphonic acid. Formed, together with the (β)-isomeride, by dissolving (1,3,4)-xylenol in H_2SO_4 (J.). FeCl_3 gives a violet-blue colour.— NaA' . Tables.— KA' . Plates.— BaA' . Leaflets.

m-Xylenol (β)-sulphonic acid

$\text{C}_6\text{H}_4\text{Me}_2(\text{OH})\text{SO}_3\text{H}$ [1:3:4:2] (Jacobsen, *A.* 195, 253). Formed as above. Coloured violet-blue by FeCl_3 . Converted by potash-fusion into (2,5,1)-*oxy*-toluic acid.— NaA' 4aq. Laminae.— BaA' . Minute needles, less soluble than the Ba salt of the (α)-acid. By sulphonating (1,3,4)-xylenol by ClSO_3H , Hodgkinson (*C. J.* 63, 110) obtained a xylenol sulphonic acid yielding BaA' 3aq.

m-Xylenol sulphonic acid

$\text{C}_6\text{H}_4\text{Me}_2(\text{OH})\text{SO}_3\text{H}$ [1:3:6:4]. Formed from $\text{C}_6\text{H}_4\text{Me}_2(\text{NH}_2)\text{SO}_3\text{H}$ by the diazo-reaction (Sartig, *A.* 280, 886). Slender needles, v. sol. water and alcohol. The acid and its salts give with FeCl_3 a bluish-violet colour turned green by alcohol.— KA' .— BaA' 2aq. Needles, v. e. sol. water.— PbA' 2aq.

Ethyl derivative $\text{C}_6\text{H}_4\text{Me}_2(\text{OEt})\text{SO}_3\text{H}$. Formed by heating diazo-*m*-xylene sulphonic acid with alcohol under pressure. Minute tables, v. sol. water and alcohol.— BaA' 3aq. Minute plates, v. sol. water.

p-Xylenol sulphonic acid. Formed by dissolving *p*-xylenol in warm H_2SO_4 . Hydrated

leaflets.— NaA' 5aq. Tables.— BaA' . Minute needles.

Reference.—NITRO-XYLENOL SULPHONIC ACID. XYLENYL-AMIDOXIM *v.* DI-METHYL-BENZOIC ACID.

XYLIDIC ACID is TOLUENE DICARBOXYLIC ACID.

o-OXYLIDINE

$\text{C}_6\text{H}_4\text{Me}_2(\text{NH}_2)$ [1:2:3].—

Di-methyl-phenyl-amine. *Amido-xylene*. Mol. w. 121. (223° i.v.) at 739 mm. S.G. 1.991. Obtained by reducing di-bromo-*o*-xylydine $\text{C}_6\text{H}_3\text{Br}_2(\text{NH}_2)$ [1:2:4:5:3] with sodium-amalgam in the cold (Töhl, *B.* 18, 2562). Got also by heating (1,2,4)-xylenol with NH_4Br and ammonio-zinc bromide at 300° (Müller, *B.* 20, 1039). Prepared from *o*-xylene by nitration and reduction (Nölting a. Forel, *B.* 18, 2671; Wroblewski, *B.* 18, 2904). Oil. When oxidised by $\text{K}_2\text{Cr}_2\text{O}_7$ and H_2SO_4 , yields a small quantity of *o*-xyloquinone [55°]. Converted by the diazo-reaction into *o*-xylenol [73°]. H_2SO_4 and HNO_3 give (4,1,2,3)-nitro-xylydine [114°] and (6,1,2,3)-nitro-xylydine [65°] (Nölting a. Stoecklin, *B.* 24, 567).—Salts: $\text{B}'\text{HCl}$ aq. Plates. Begins to sublime at 100°.— $\text{B}'\text{HNO}_3$. Needles.— $\text{B}'_2\text{H}_2\text{SO}_4$. Large plates, sl. sol. water.

Acetyl derivative $\text{C}_6\text{H}_4\text{Me}_2\text{NHAc}$. [134°]

(N. a. F.); [131°] (T.; W.). Slender needles.

i-O-Xylydine $\text{C}_6\text{H}_4\text{Me}_2(\text{NH}_2)$ [1:2:4]. [49°].

(226°). S.G. 1.775. Prepared from *o*-xylene by nitration and reduction (Jacobsen, *B.* 17, 159). Got also by heating *m*-toluidine hydrochloride with MeOH at 300° (Limpach, *B.* 21, 643). Monoclinic crystals, not coloured by exposure to light and air. Gives no colour with bleaching powder. Its solutions colour pine-wood yellow. On nitration it yields (6,1,2,4)-nitro-xylydine [137°] and an isomeride [80°] (N. a. S.). Yields a saffranine on oxidation together with di-amido-di-phenyl-amine (Nietzki, *B.* 19, 8163).—Salt: $\text{B}'\text{HCl}$ aq. Prisms, v. sol. water. Yields ψ -cumidine when heated with MeOH at 310° (N. a. F.).

Acetyl derivative $\text{C}_6\text{H}_4\text{Me}_2(\text{NHAc})$. [99°].

o-m-Xylydine $\text{C}_6\text{H}_4\text{Me}_2(\text{NH}_2)$ [1:3:2]. (β)-

Xylydine (214° i.v.) at 739 mm. (N. a. F.). S.G. 2.9942 (W.). Formed by distilling *p*-amido-mesitylenic acid with lime (Schmitz, *A.* 193, 179) and by reducing *c*-nitro-*m*-xylene (Grevink, *B.* 17, 2430). Obtained from commercial xylydine by crystallisation of the sulphate; the last mother-liquor depositing crystals which are converted into the acetyl derivative by distillation with HOAc . The acetyl derivative is saponified by treatment with dilute (25 p.c.) H_2SO_4 (Nölting a. Pick, *B.* 21, 8150; cf. Wroblewski, *B.* 12, 1226). Gives *m*-xyloquinone [73°] on oxidation (Nölting a. Forel, *B.* 18, 2676). Yields (4,1,3,2)-nitro-xylydine [82°] on nitration (Nölting a. Stoecklin, *B.* [8] 5, 881).—Salts: $\text{B}'\text{HCl}$.— $\text{B}'\text{HCl}$ 3aq. S. 9-7 at 18°. Monoclinic plates. Yields mesidine on heating with MeOH at 310°.— $\text{B}'\text{HNO}_3$. S. 2-2. Needles.— $\text{B}'_2\text{H}_2\text{SO}_4$. Very soluble needles.— $\text{B}'_2\text{H}_2\text{SO}_4$ 2aq. S. 60.

Acetyl derivative [174°] (G.); [176.5°] (N. a. F.). Needles.

Benzoyl derivative [140°]. Needles. Yields benzoyl-nitro-xylylidine [178°] on nitration (Hübner, A. 208, 318).

s-m-Xylylidine $C_8H_7Me_2(NH_2)$ [1:3:5]. (222° i.v.). S.G. 1.0972. Formed by reduction of s-nitro-m-xylene [71°] (Thöl, B. 18, 362; Nölting a. Forel, B. 18, 2678). On oxidation by $K_2Cr_2O_7$ and H_2SO_4 it gives m-xyloquinone [78°]. By boiling the diazo-compound with water xynol [68°] is formed. $ClCO_2Et$ forms $C_8H_7Me_2NH.CO_2Et$ [77.5°] (Frentzel, C. C. 1888, 1361). —B'HCl. MeOH at 250°–300° yields isocumidine $C_8H_7Me_2(NH_2)$ [5:4:3:1] (Limpach, B. 21, 643). —B'H₂SO₄ aq. —B'HNO₃ S. 4.66 at 13°.

Acetyl derivative [140.5°] (N. a. F.); [138°] (T.); [144.5°] (W.). Colourless plates (from alcohol or ether).

i-m-Xylylidine $C_8H_7Me_2(NH_2)$ [1:3:4]. (a)-Xylylidine. (215°) at 745 mm. (G.). S.G. 1.09184 (H.). S.V. 148.3.

Formation.—1. By reducing i-nitro-m-xylene (Deumelandt, A. 144, 273; Tavildaroff, B. 2, 553; Wroblewski, A. 192, 215; 207, 91; Grevingk, B. 17, 2430; Wallach, A. 258, 331). It may be isolated from commercial xylylidine by conversion into hydrochloride and several crystallisations from water; the yield being about 40 p.c. (Nölting a. Forel, B. 18, 2677).—2. By heating o- and p-toluidine hydrochloride with MeOH at 300° (Hofmann, B. 9, 1295; Limpach, B. 21, 640).—3. By distilling (4,3,1,5)-amido-mesitylenic acid with lime (Schmitz, A. 193, 177).—4. By heating i-m-xynol with ammonium-zinc bromide and NH_4Br (Müller, B. 20, 1039).

Reactions.—1. When dissolved in H_2SO_4 (10 pts.) it yields $C_8H_7Me_2(NH_2)(NO_2)$ [1:3:4:6] [123°] on nitration (Nölting a. Collin, B. 17, 265).—2. The hydrochloride heated with MeOH at 310° yields mesidine.—3. $ClCO_2Et$ forms $C_8H_7Me_2NH.CO_2Et$ [57°] (Frentzel, C. C. 1888, 1361).—4. When mixed with di-amido-di-phenylamine it yields a saffranine on oxidation (Nietzki, B. 19, 3163).—5. When m-xylylidine (4 pts.) is heated with S (1 pt.) at 190° it gives off H_2S and forms a base $C_{10}H_{10}N_2S$ [107°] (283° at 14 mm.) which crystallises from alcohol in yellowish-white prisms and yields $C_{10}H_{10}AcN_2S$ [227°] (Anschütz a. Schultz, B. 22, 582). By further heating with sulphur a homologue of primuline is formed.—6. *Cinnanthol* forms oily $C_{10}H_{10}NO$ (Leeds, B. 16, 288).—7. *Acrolein* yields $C_{10}H_{10}N$, a reddish-yellow mass which on distillation yields cryptidine $C_{11}H_{11}N$ (270°) (Leeds, A. C. J. 5, 1).

Salts.—B'HCl. Monoclinic prisms. —B'HCl aq. Plates (Staedel a. Hölz, B. 18, 2919). —B'H₂PtCl₆. —B'HBz. —Trimetric plates. —B'HNO₃. —B'H₂SO₄ 4 aq. Cubes. Loses xylylidine on evaporation of its solution (Nölting a. Pick, B. [2] 50, 606). —B'H₂PO₄. Only phosphate formed (Lewy, B. 19, 2728). —B'H₂C₂O₄. S. 3.32 at 18°. —B'H₂ZnCl₂ (Lachovitch, M. 9, 514). —B'HgH₂(SO₄)₂ aq. —B'₂Cu₂H₂(SO₄)₂ (Deniges, C. R. 112, 870).

Formyl derivative $C_8H_7Me_2NH.OHO$. [111°] (G.); [114°] (G. a. M.). Got by heating the base (12 g.) with formic acid (5 g.) at 150° (Gasiarowski a. Merz, B. 18, 1011; Gudemann,

B. 21, 2549). Crystals (from water). Converted by P₂S₅ at 100° into the thioformyl derivative [105°].

Mono-acetyl derivative

$C_8H_7Me_2(NHAc)$. [129°]. Needles or plates (from dilute alcohol). P₂S₅ forms the compound $C_8H_7Me_2NH.CSMe$ [95°] (Jacobsen a. Ney, B. 22, 907).

Di-acetyl derivative $C_8H_7Me_2NAc_2$. [60°]. Formed, together with the mono-acetyl derivative, by boiling the base with Ac₂O (Wallach, A. 258, 301).

Benzoyl derivative $C_8H_7Me_2NHBz$. [192°]. Needles (Hübner, A. 208, 318). Converted by HNO₃ into the nitro-benzoyl derivative [184°] which is reduced by tin and HOAc to $C_8H_7Me_2<\overset{NH}{N}>CPh$ [195°].

Phthalyl derivative [158°]. Prisms (from alcohol).

p-Xylylidine $C_8H_7Me_2(NH_2)$ [1:4:2]. [15.5°] (Michael, B. 26, 89). (215° i.v.) at 789 mm. (N. a. F.); (213.5° uncor.) (M.); (220°) (S.). S.G. 1.0980. Obtained from m-xylene by nitration and reduction (Schaumann, B. 11, 1537; Nölting a. Forel, B. 18, 2664; 19, 2680). Occurs to the extent of about 25 p.c. in commercial xylylidine, from which it may be isolated by dissolving in warm H_2SO_4 and pouring into hot water. The sparingly soluble m-xylylidine sulphonic acid crystallises out, and the mother-liquor, after successive treatment with CaCO₃ and Na₂CO₃, yields on evaporation sparingly soluble, pearly plates of sodium p-xylylidine sulphonate, which on distillation with lime give p-xylylidine almost without loss. May also be got from crude xylylidine by means of its benzylidene derivative.

Reactions.—1. Oxidised by $K_2Cr_2O_7$ and H_2SO_4 to p-xyloquinone [128°], the yield being 70 p.c.—2. Converted by the diazo-reaction into p-xynol [75°] (210°).—3. On heating with sulphur it yields $C_{10}H_{10}N_2S$ [144°], which crystallises from alcohol in yellowish needles, and yields an acetyl derivative [212°] (Anschütz a. Schultz, B. 22, 585).—4. The hydrochloride heated with MeOH at 290° under pressure forms ψ-cumidine (Limpach, B. 21, 646).—5. *Benzoic aldehyde* forms $C_8H_7Me_2N.CHPh$ [102°] (Pflug, A. 255, 168). The same body [96°] is got by adding benzoic aldehyde to an alcoholic solution of thionyl-p-xylylidine (Michaelis, A. 274, 237).

Salts.—B'HCl aq. Leaflets, subliming at 125°–130° in needles. —B'HNO₃. Needles. —B'H₂SO₄. Plates, sl. sol. water. —B'H₂C₂O₄.

Formyl derivative $C_8H_7Me_2NH.O$. [112°]. Needles (Pflug, A. 255, 168).

Acetyl derivative $C_8H_7Me_2NHAc$. [189°]. Prisms. Yields on nitration acetyl-nitro-p-xylylidine [192°].

Bromo-acetyl derivative

$C_8H_7Me_2NH.CO.CH_2Br$. [145°]. Formed from bromo-acetyl bromide and p-xylylidine in benzene (Abenius, J. pr. [2] 40, 435). Needles (from dilute alcohol). Boiling alcoholic potash converts it into an azine and the compound $C_8H_7Me_2NH.CO.CH_2.OEt$ [50°].

Oxalyl derivative $(C_8H_7Me_2NH)_2C_2O_4$. Formed by heating the oxalate at 130°. Needles, subliming at 125°. An oxalyl-xylylidine [204°] was obtained by Genz (B. 8, 227) from crude, commercial xylylidine.

Benzoyl derivative $C_6H_5Me_2NHBz$. [140°]. Needles.

References.—BROMO-, CHLORO-, and NITROXYLIDINE.

XYLIDINE SULPHONIC ACID *v.* AMIDOXYLENE SULPHONIC ACID and BROMO- and NITROXYLIDINE SULPHONIC ACIDS.

XYLIDINIC ACID *v.* TOLUENE DICARBOXYLIC ACID.

XYLINDEIN. C , 65.5 p.c.; H , 4.7 p.c.; N , 1.0 p.c. A green colouring matter in green decayed wood (Rommier, *C. R.* 66, 108; Liebermann, *B.* 7, 1102). Extracted by phenol and *ppd.* by alcohol or ether. Four-sided blue plates, with coppery lustre. H_2SO_4 forms a green solution. Rideal (*C. N.* 53, 277) finds that the blue substance in decayed birch-wood is soluble in chloroform, while the blue resin obtained from coniferin by successive treatment with H_2SO_4 and water is insol. chloroform.

XYLITONE $C_{12}H_{20}O_2$. *Xylite oil*. (252°) (Pinner, *B.* 15, 589; 16, 1729); (*c.* 240°) (Claisen a. Ehrhardt, *B.* 22, 1013). S.G. .935. A product of the action of HCl on acetone (P.). Formed also by the action of $NaOEt$ on mesityl oxide in ether, and in the preparation of acetylacetone by the action of boiling $EtOAc$ and $NaOAc$ on acetone (C. a. E.). Oil, easily resinified by strong acids.

Dixylitone $C_{12}H_{20}O_2$. (310°–320°). A product of the action of HCl on acetone (Pinner).

XYLOHYDROQUINONE *v.* HYDROXYLOQUINONE.

XYLOIC ACID *v.* DI-METHYL-BENZOIC ACID.

XYLONIC ACID $C_8H_{10}O_4$. [α]_D = 17.48°. Formed by oxidising xylol with bromine (Tollens, *A.* 260, 307). Dextrorotatory. Its Ca , Zn , and Ag salts are amorphous.— SnA' . [α]_D = +12.14°.

XYLONITRILE *v.* Nitrile of DI-METHYL-BENZOIC ACID.

O-XYLOQUINONE $C_8H_6O_2$ *i.e.*

$C_8H_6Me_2O_2$ [1:2:3:6]. [55°]. Formed by oxidation of *c-o*-xylidine by $K_2Cr_2O_7$ and H_2SO_4 , the yield being about 10 p.c. (Nölting a. Forel, *B.* 18, 2673). Yellow needles (by sublimation), *v. sl.* sol. water, *m. sol.* alcohol and ether.

m-Xyloquinone $C_8H_6Me_2O_2$ [1:3:2:5]. [73°]. Formed by oxidation either of *c-m*- or *s-m*-xylidine with $K_2Cr_2O_7$ and H_2SO_4 (Nölting a. Forel, *B.* 18, 2679). Got also by oxidation of mesidine (Nölting a. Baumann, *B.* 18, 1151). Yellow needles.

p-Xyloquinone $C_8H_6Me_2O_2$ [1:4:2:5]. *Phlorone*. *Metaphlorone*. Mol. w. 186. [124°].

Formation.—1. Occurs, together with toluquinone and other bodies, among the products of the action of MnO_2 and H_2SO_4 on coal-tar and beechwood-tar (Rommier a. Bouillon, *C. R.* 55, 214; Gorup-Besanez a. von Rad, *Z.* [2] 4, 560; Carstanjen, *J. pr.* [2] 23, 425).—2. By oxidation of *p*-xylylene-diamine (Nietzki, *B.* 13, 472; *A.* 215, 168).—3. By oxidation of ψ -cureenol (Carstanjen, *J. pr.* [2] 23, 430).—4. By oxidation of ψ -cumidine by CrO_3 (Nölting a. Th. Baumann, *B.* 18, 1151; Sutkowski, *R.* 20, 977). 5. By distilling xylidine (218°) with H_2SO_4 and MnO_2 , the yield being 5 p.c. (C.).—6. By oxidation of *p*-xylidine with $K_2Cr_2O_7$ and H_2SO_4 , the yield being over 70 p.c. (Nölting, Witt, a. Forel,

B. 18, 2667).—7. By heating diacetyl with dilute $NaOHAq$ (Van Pechmann, *B.* 21, 1420).

Preparation.—1. Commercial xylene (180°–140°) is heated with H_2SO_4 at 100° for six days; the product poured into water; neutralised by $CaCO_3$; treated with K_2CO_3 ; and the K salts of the sulphonic acids fused with potash. The product is dissolved in water, acidified, and extracted with ether; and the mixture of xylenols so obtained is dissolved in warm H_2SO_4 , and then diluted with water and distilled with MnO_2 . Crystals of *p*-xyloquinone appear in the condenser and receiver (Carstanjen, *J. pr.* [2] 23, 427).—2. 'Yellow carboic acid' or 'creosote', the mother-liquor from which phenol has crystallised, is dissolved in H_2SO_4 , diluted with water, and then distilled with MnO_2 . The solid found in the receiver is crystallised from alcohol when the first crop of crystals is xyloquinone (E. Carstanjen, *J. pr.* [2] 23, 423).

Properties.—Long yellow needles (from benzene), *sl. sol.* water and cold alcohol, *v. sol.* ether. May be sublimed. Volatile with steam.

Reactions.—1. Distilled with *sync-dust* gives a hydrocarbon that oxidises to terephthalic acid.—2. Reduced by aqueous SO_2 to hydroxyxyloquinone.—3. Conc. HCl converts it into a mixture of mono- and di-chloro-hydro-xyloquinones, $C_8H_5ClMe_2(OH)_2$ [147°] and $C_8H_4Cl_2Me_2(OH)_2$ [175°].

Mono-oxim $C_8H_6Me_2O(NOH)$. *Nitroso-p-xylitol*. [168°]. Formed by heating *p*-xyloquinone (2 pts.) with an alcoholic solution of hydroxylamine hydrochloride (1 pt.) (Goldschmidt a. Schmid, *B.* 18, 568; Sutkowski, *B.* 20, 978). Obtained also by adding KNO_3 and excess of $HOAc$ to an alkaline solution of *p*-xylitol (Olivieri, *G.* 12, 162). Yellowish needles (from alcohol), *v. sol.* alcohol, ether, and benzene, *insol.* cold water. Alkalis form a deep orange-red solution. Reduced by $SnCl_2$ to amido-*p*-xylitol. Oxidised by alkaline K_2FeCy_6 to nitro-*p*-xylitol.

Di-oxim $C_8H_6Me_2(NO)_2$. [272°]. Formed by boiling the quinone (1 mol.) with an alcoholic solution of hydroxylamine hydrochloride (2 mols.) (Sutkowski, *B.* 20, 977). *V. sl. sol.* alcohol, acetic acid, and benzene, *insol.* water. Dissolves in alkalis with a yellow colour. By tin and HCl it is reduced to xylene-*p*-diamine. Its di-acetyl derivative $C_8H_4Me_4(NOAc)_2$ crystallises from acetic acid in small yellow prisms, [170°], *v. sol.* alcohol and benzene.

References.—DI-BROMO- and CHLORO-XYLOQUINONE.

XYLORCIN *v.* DI-OXY-XYLENE.

XYLOSE *v.* p. 538.

XYLOSTEIN. A glucoside in the berries of *Lonicera Xylosteum* (Hübschmann, *J.* 1856, 691; Enz, *C. C.* 1856, 893). Crystalline, *insol.* water, *sol.* alcohol and ether.

XYLOYL-BENZOIC ACID *v.* PHENYL XYL KETONE CARBOXYLIC ACID.

XYLOYL-FORMIC ACID *v.* XYLYL-GLYOXALIC ACID.

pp-DIXYLYL C_8H_8 *i.e.*

[4:1:3] $C_8H_8Me_2.C_8H_8Me_2$ [3:4:1]. [125°]. Prepared by distilling mercury di-*p*-xyl (Jacobsen, *B.* 14, 2112). Long needles (from alcohol).

Dixylol. (290°–295°). Formed from bromo-*m*(?)-xylene and Na (Fittig, *A.* 14, 88). Liquid.

Di-xylyl (so-called). (295°) (Oliveri, *G.* 12, 158). Is got by warming commercial xylene with H_2SO_4 , but never from xylene which has been made from xylene sulphonic acid. Hence it is probably not a benzene derivative (Armstrong, *C. J.* 45, 150). It is a colourless, fluorescent liquid, smelling like copaiba balsam.

XYLYL-ACETAMIDE *v.* *Acetyl derivative of Xylidine and Amide of XYLYL-ACETIC ACID.*

XYLYL-ACETIC ACID

[1:3:4] $C_6H_5Me_2CH_2CO_2H$. [102°]. Formed from its amide, which is got by the action of yellow ammonium sulphide on xylol methyl ketone (Willgerodt, *B.* 21, 534). Slender needles.

Amide $C_6H_5CH_2CO_2NH_2$. [183°].

Reference.—OXY-XYLYL-ACETIC ACID.

XYLYL ALCOHOL is TOLYL-CARBINOL.

XYLYL-AMIDO-ACETIC ACID $C_6H_5H_3NO_2$ *i.e.*

[1:3:4] $C_6H_5Me_2NH.CH_2.CO_2H$. [134°]. Formed by boiling *m*-xylidine (2 mols.) with water and chloro-acetic acid (1 mol.) (Ehrlich, *B.* 16, 205). Prisms (from dilute alcohol). Insol. water, *v.* sol. aëcis.

Xylide $C_6H_5NH.CH_2.CO.NHC_6H_5$. [128°]. Formed by boiling xylidine (2 mols.) with chloro-acetic ether (1 mol.). Thick needles (from alcohol), insol. water and $HClAq$.

XYLYL-AMIDO-CROTONIC ETHER

[1:3:4] $C_6H_5Me_2NH.CMe:CH.CO_2Et$. Formed from *m*-xylidine and acetoacetic ether (Conrad a. Limpach, *B.* 21, 526). Decomposed on heating into (*Py.* 1, 3; *B.* 2, 4)-oxy-tri-methyl-quinoline, di-xylyl-urea, and alcohol.

XYLYL-AMIDO-ETHYL-PHTHALIMIDE

[1:3:4] $C_6H_5Me_2NH.C_2H_4.N:C_6H_4O_2$. [123°]. Formed by heating bromo-ethyl-phthalimide with *m*-xylidine at 140° (Newman, *B.* 24, 2197). Small needles, *v. e.* sol. benzene, sl. sol. cold alcohol.

DI-*m*-XYLYL-DI-AMIDO-OIAZTHIOLE

$C_{18}H_{20}N_4S$ *i.e.* $S \begin{smallmatrix} \nearrow C(NHC_6H_5)_2 \\ \searrow C(NHC_6H_5)_2 \end{smallmatrix} N$. [79°]. Formed by oxidising (1,3,4)-xylol-thio-urea with aqueous H_2O_2 (Hector, *B.* 23, 368). Insol. water. Forms a very soluble hydrochloride.— $B'AgNO_3$. Explodes on heating. Blackened by sunlight.— $B'C_6H_5N_3O_2$. [218°]. Yellow crystals, *v. sol.* alcohol. Cyanogen passed into its alcoholic solution forms $C_{18}H_{20}N_4SCy_2$. [103°].

Acetyl derivative $C_{18}H_{20}AcN_4S$. Needles.

Benzoyl derivative $C_{18}H_{20}BzN_4S$. [212°].

Nitrosamine $C_{18}H_{20}(NO)_2N_4S$. [146°].

XYLYLAMINE *v.* **XYLIDINE** and **METHYL-BENZYL-AMINE**.

Di-*o*-xylyl-amine $(C_6H_5)_2NH$. (330°–345°). Formed, together with xylidine, by heating (1,2,4)-xynol with ammonio-zinc bromide and NH_4Br at 300° (Müller, *B.* 20, 1039). Liquid, solidified at a very low temperature.

Di-*m*-xylyl-amine. (305°–310°). Formed in like manner from *m*-xylidine. Oil.

Di-xylyl-amine. [162°]. Formed, together with a liquid isomeride, by heating xylidine with its hydrochloride (Girard a. Vogt).

XYLYL-BENZYL-AMINE $C_{11}H_{11}N$ *i.e.*

$C_6H_5Me_2NH.CH_2Ph$. (*c.* 205° at 15 mm.). Formed by heating *m*-xylidine with benzyl chloride at 160° (Joblin-Gonnet, *Bl.* [3] 6, 21). Yellowish oil, sl. alcohol and benzene.

***p*-Xylyl-benzyl-amine**

[1:4:2] $C_6H_5Me_2NH.CH_2Ph$. (322°) (Pflug, *A.* 255, 168).

***o*-XYLYL BENZYL KETONE** $C_{16}H_{16}O$ *i.e.* $C_6H_5Me_2CO.CH_2Ph$. [95°]. (210°–220° at 25 mm.). Formed from *o*-xylene, phenyl-acetic chloride, and $AlCl_3$ (Wege, *B.* 24, 3540). Plates, sol. alcohol, *v.* sol. ether. Yields a crystalline oxim. $NaOEt$ and benzyl chloride yield $C_6H_5Me_2CO.CH(CH_2Ph)Ph$ [75°].

***m*-Xylyl benzyl ketone**

[1:3:4] $C_6H_5Me_2CO.CH_2Ph$. (350°). Formed, together with a smaller quantity of an isomeride [93°], by the action of $AlCl_3$ on a mixture of *m*-xylene and phenyl-acetic chloride (Söllscher, *B.* 15, 1681). Yields $C_6H_5Me(CO_2H)_2$ [3:4:1] on oxidation. $NaOEt$ and benzyl chloride form oily $C_6H_5CO.CHPh.CH_2Ph$ (365°–375°).

***p*-Xylyl benzyl ketone** $C_6H_5CO.CH_2Ph$. (220°–230° at 26 mm.). Formed in like manner from *p*-xylene (Wege). Yields an oxim [99°] and a phenyl-hydrazide [96°]. $NaOEt$ and benzyl chloride yield $C_6H_5CO.CHPh.CH_2Ph$ [60·5°].

***m*-XYLYL-BENZYL-THIO-UREA**

$C_6H_5NH.CS.NHCH_2Ph$. [85°]. Formed from benzyl-thiocarbimide and *m*-xylidine in alcohol (Dixon, *C. J.* 59, 558). Monoclinic prisms, *v.* sol. boiling alcohol and chloroform.

XYLYL BROMIDE *v.* **BROMO-XYLENE**.

XYLYL-*tert*-BUTANE $C_6H_5Me_2CMe_2$. (201°). Formed from *m*-xylene, isobutyl bromide, and $AlCl_3$ (Baur, *B.* 24, 2840). Got also from isobutyl alcohol, *m*-xylene, and H_2SO_4 or $ZnCl_2$ (Nölting, *B.* 25, 791). Oil, yields mesitylenic and trimetic acids on oxidation.

XYLYL-BUTYL ALCOHOL

[2:4:1] $C_6H_5Me_2CHPr.OH$. (above 270°). Got by reducing xylol propyl ketone with zinc-dust and $KOHAq$, or with sodium-amalgam (Claus, *J. pr.* [2] 46, 474). Oil, *v.* sol. alcohol and ether.

Tri-xylyl-butyl alcohol $(C_6H_5)_3C.CMe_2OH$. (above 300°). Formed from *xylene*, tri-chloro-*tert*-butyl alcohol, and $AlCl_3$ (Willgerodt a. Genieser, *J. pr.* [2] 37, 361). Oil, smelling like mushrooms.

***m*-XYLYL-*n*-BUTYRIC ACID**

[1:3:4] $C_6H_5Me_2CH_2CH_2CH_2CO_2H$. [70°]. Formed by saponifying the amide (Claus, *J. pr.* [2] 46, 476). Needles, *v.* sol. hot water. May be sublimed.— BaA' , 4aq.— CaA' , 4aq. Prisms, *v.* sol. water and alcohol.

Amide $C_6H_5Me_2C_4H_9CO.NH_2$. [124°]. Got by heating xylol propyl ketone with *S* and ammonium sulphide in sealed tubes at 250°. Flat silky needles. May be sublimed.

***p*-Xylyl-*n*-butyric acid**

[1:4:2] $C_6H_5Me_2CH_2CH_2CH_2CO_2H$. [70°]. Needles, sl. sol. cold water.— BaA' , 4aq.— CaA' , 4aq. Needles, sol. water and alcohol.

imide $C_6H_5C_4H_9CO.NH_2$. [125°]. Formed from *p*-xylol propyl ketone (*C.*). Flat needles, *v.* sol. hot water.

***n*-Xylyl-isobutyric acid**

[1:3:4] $C_6H_5Me_2CH_2CHMe.CO_2H$. [70°]. Flat pearly needles, sol. hot water, alcohol, and ether. May be sublimed.

Amide $C_6H_5C_4H_9CO.NH_2$. [120°]. Got by heating xylol isopropyl ketone with *S* and ammonium sulphide at 235° (Claus, *J. pr.* [2] 46, 458). Needles, sol. hot water.

XYLYL-CARBAMIC ACID

[1:3:4] $C_6H_4Me_2.NH.CO_2H$. *Ethyl ether EtA'*. [58°]. Formed from *m*-xylydine and chloroformic ether (Hofmann, *B.* 3, 657; Frentzel, *C. C.* 1888, 1361). Needles.

Xylyl-carbamic acid

[1:3:5] $C_6H_4Me_2.NH.CO_2H$. *Ethyl ether EtA'*. [77-5°] (Frentzel).

Di-*p*-xylyl-carbinol

[(2:5:1) $C_6H_4Me_2$]. $CH.OH$. [131°]. Formed by reducing di-*p*-xylyl ketone with zinc-dust and KOH (Elbs, *J. pr.* [2] 35, 484; *B.* 19, 408). White needles (from alcohol), nearly insol. Aq.

XYLYL CYANATE [1:3:4] $C_6H_4Me_2.N.CO$. (205°) (Frentzel, *C. C.* 1888, 1361).

Xylyl cyanate [1:3:5] $C_6H_4Me_2.N.CO$. (208-5°).

XYLYL CYANURATE

[1:3:4] $(C_6H_4Me_2)_3N_3C_3O_3$. [162°] (Frentzel, *C. C.* 1888, 1361).

XYLYLENE ALCOHOL v. Di-oxy-xylylene.

XYLYLENE-DI-ALLYL-DI-THIO-DI-UREA $(CH_3)_2C_6H_4(NH.CS.NH.C_2H_5)_2$ [1:4:2:6]. [112-5°]. Made from *p*-xylylene diamine and allyl thiocarbimide (Lellmann, *A.* 228, 252). Needles (from alcohol). Not decomposed on melting.

***m*-XYLYLENE-*m*-DIAMINE**

$C_6H_4(CH_3)_2(NH_2)_2$ [1:3:4:6]. *m*-Di-amido-*m*-xylylene [105°]. Formed by reduction of nitro-xylydine [123°] or of di-nitro-xylylene [93°] (Fittig, *A.* 147, 18; Grevingk, *B.* 17, 2426; Witt, *B.* 21, 2419). White crystals. Sublimable. Does not yield a eurhodine on boiling with nitroso-dimethylaniline, NaOAc, and HOAc. — $B''2HCl$. — $B''H_2SnCl_4$. — $B''H_2SO_4$. Crystalline, v. sol. Aq.

***m*-Xylylene-*o*-diamine**

$C_6H_4Me_2(NH_2)_2$ [1:3:5:6] [78-5°]. Formed by reduction of [2:4:1] $C_6H_4Me_2.N_2.C_6H_4Me_2.NH_2$ [1:3:5:6] (Nölting, *a.* Forel, *B.* 18, 2688) and also by the action of tin and HClAq on di-bromo-di-nitro-*m*-xylylene [191°] (Jacobsen, *B.* 21, 2821), and on (5,1,3,6)-nitro-xylydine (Hofmann, *B.* 9, 1298). Plates (from water), sl. sol. cold benzene, sol. ether.

***m*-Xylylene-*m*-diamine**

$C_6H_4Me_2(NH_2)_2$ [1:3:4:2]. [64°]. Formed by reduction of nitro-xylydine [78°] or of di-nitro-*m*-xylylene [82°] (Grevingk, *B.* 17, 2426). White needles. Gives a Bismarck brown with nitrous acid and a chrysoidine with diazobenzene.

***p*-Xylylene-*o*-diamine**

$C_6H_4Me_2(NH_2)_2$ [1:4:2:3]. [75°]. Formed by reduction of *o*-di-nitro-*p*-xylylene (Lellmann, *A.* 228, 251; Nölting, *B.* 19, 145). White needles (by sublimation). Gives a deep-red colour with $FeCl_3$.

***p*-Xylylene-*m*-diamine**

$C_6H_4Me_2(NH_2)_2$ [1:4:2:6]. [102°]. Formed by reducing (2,6,1,4)-di-nitro-xylylene (L.; N.). Needles (by sublimation). Behaves like a *m*-diamine.

***p*-Xylylene-*p*-diamine**

$C_6H_4Me_2(NH_2)_2$ [1:4:2:5]. [142°] (S.); [147°] (N. a. F.); [150°] (N.). *Formation*.—1. By reduction of xylylene-azoxylidene (amido-azo-xylylene) [2:5:1] $C_6H_4Me_2.N_2.C_6H_4Me_2.NH_2$ [1:2:5:4] by zinc and HClAq (Nietzki, *B.* 13, 471; Nölting, *a.* Forel, *B.* 18, 2686).—2. By reduction of nitro-xylydide [142°] (Nölting, Witt, *a.* Forel, *B.* 18, 2666; von Kostanecki, *B.* 19, 2818; Marckwald, *B.* 23, 1021).—3. By reduction of the di-oxim of

p-xyloquinone $C_6H_4Me_2(NO_2)_2$ with tin and HCl (Sutkowski, *B.* 20, 979).

Properties.—Colourless needles, sol. hot water and alcohol, m. sol. benzene and ether. Yields xyloquinone [123°] on oxidation. Not oxidised by exposure to air. May be sublimed.

Salts.— $B''2HCl$. Colourless leaflets. — $B''H_2SO_4$. Crystalline meal.

***o*-Xylylene-*exo*-diamine**

[1:2] $C_6H_4(CH_2.NH_2)_2$. Formed by heating the phthalimide $C_6H_4(CH_2.N:C_2O_2.C_6H_4)_2$ with conc. HClAq at 200° (Strassmann, *B.* 21, 579). Alkaline liquid, smelling strongly like ammonia. Absorbs CO_2 . Gives with $FeCl_3$ a pp. of yellowish-red needles. — $B''2HCl$. — $B''2H_2AuCl_4$. Yellow plates. — $B''2C_6H_4N_2O_2$. Yellow needles, decomposing above 170° without melting.

Acetyl derivative $C_6H_4(CH_2.NHAc)_2$. [140°].

Benzoyl derivative $C_6H_4(CH_2.NH.Bz)_2$. [168°].

***m*-Xylylene-*exo*-diamine**

[1:3] $C_6H_4(CH_2.NH_2)_2$. (247°). Formed by the action of conc. hydrochloric acid at 220° on the $C_6H_4(CH_2.N:C_6H_4O_2)_2$ [237°], which is got by heating potassium phthalimide with di-*o*-bromo-*m*-xylylene (Brümme, *B.* 21, 2705). Liquid, sol. water, miscible with alcohol and ether. Absorbs CO_2 . — $B''2HCl$. Needles (from water). — $B''2H_2PtCl_4$. — $B''C_6H_4N_2O_2$. Yellow spangles, decomposing at 187°.

Acetyl derivative $C_6H_4(CH_2.NHAc)_2$. [119°]. Crystalline mass, v. sol. hot water.

Reference.—NITRO-XYLYLENE-DIAMINE.

XYLYLENE-BENZENYL-AMIDINE v. BENZENYL-XYLYLENE-DIAMINE.

XYLYLENE BROMIDE v. Di-BROMO-XYLYLENE.

XYLYLENE-CHLORO-MALONIC ETHER v.

CHLORO-XYLYLENE-MALONIC ETHER.

Xylylene-*exo*-di-chloro-malonic ether v. Di-CHLORO-PHENYLENE-DI-METHYL-DI-MALONIC ETHER.

XYLYLENE-ETHENYL-AMIDINE $C_{10}H_{12}N_2$

i.e. $CM_2 < \begin{smallmatrix} NH \\ N \end{smallmatrix} > C_6H_4Me_2$. Formed by reducing $C_6H_4Me_2(NO_2)(NHAO)$ [1:3:5:4] with tin and HCl (Hobrecr, *B.* 5, 922). Resinous mass. — $B'HCl$. Large needles. — $B''H_2PtCl_4$. — $B''HNO_3$. Long needles.

XYLYLENE IODIDE v. Di-IODO-XYLYLENE.

XYLYLENE-DI-MALONIC ACID v. PHENYLENE-DI-METHYL-DI-MALONIC ACID.

***o*-XYLYLENE SULPHIDE** C_6H_4S i.e.

$C_6H_4 < \begin{smallmatrix} CH_2 \\ CH_2 \end{smallmatrix} > S$. [o. 0°]. Formed by heating di-*o*-bromo-*o*-xylylene with K_2S (Leser, *B.* 17, 1824; Hjelt, *B.* 22, 2904). Oil, smelling like mercaptan. Very unstable, quickly turning into a black resin. — $B''HgCl_2$. Long needles.

Methylo-iodide $B'MeI$. [155°].

Di-xylylene disulphide

[1:3:4:5] $C_6H_4Me_2.S_2.C_6H_4Me_2$ [5:4:3:1]. [118°]. Formed by heating xylylene-diazosulphide at 200°–250° (Jacobsen, *a.* Ney, *B.* 22, 911). Conc. H_2SO_4 forms a l'ue liquid, remaining blue on dilution.

***u*-DI-XYLYL-ETHANE** $C_{14}H_{20}$ i.e.

$CH_3.CH(C_6H_4)_2$. (324°). S.G. d_4^{20} 0.966. Formed from ethylidene chloride, *m*-xylylene, and $AlCl_3$ (Anschütz, *B.* 18, 665; *A.* 235, 326). Oil.

Reference.—CHLORO-DI-XYLYL-ETHANE.

DI-XYLYL-ETHYLENE $C_{16}H_{20}$ i.e.

$C_6H_4Me_2.CH:CH.C_6H_4Me_2$. *Tetra-*m*-ethyl-stilbene*. [106°]. (325°–340°). Formed by distilling

$C_6H_4Me_2.CH_2.CH_2Cl$, which is got from di-chloro-di-ethyl oxide, *m*-xylene, and H_2SO_4 (Hepp, *B.* 7, 1416). Spangles (from alcohol), sol. ether and CS_2 . Unites with bromine. Oxidised by dilute HNO_3 to (1,3,4)-di-methyl-benzoic acid [122°].

Di-xylyl-ethylene $C_6H_4Me_2.CH:CH.C_6H_4Me_2$. [157°]. Formed in like manner from *p*-xylene. Plates (from alcohol). Less soluble than the preceding isomeride.

Tetra-xylyl-ethylene
 $(C_6H_4Me_2)_2C:C(C_6H_4Me_2)_2$. [245°]. Formed from xylene, $CHCl_3$, and $AlCl_3$ (Schwarz, *B.* 14, 1528). Yellow plates.

***m*-XYLYL-ETHYLENE-DIAMINE**
 $C_6H_4Me_2.NH.C_6H_4.NH_2$. (274°). Formed from *m*-xylyl-amido-ethyl-phthalimide and HCl (Newman, *B.* 24, 2197).— $B'HCl$. [173°].— $B'_2H.PtCl_6$.— $B'_2C_6H_3N_3O_7$. [141°]. Reddish-yellow needles, v. e. sol. alcohol.

DI-*m*-XYLYL-ETHYLENE DIKETONE
 $C_2H_4(CO.C_6H_4Me_2[4:3:1])_2$. [129°]. Formed from *m*-xylene, succinyl chloride, $AlCl_3$, and CS_2 (Claus, *B.* 20, 1375). Needles, insol. water, v. sol. alcohol and ether. Dilute HNC_4 oxidises it to (1,3,4)-di-methyl-benzoic acid.

Oxim $C_6H_4(C(OH).C_6H_4)_2$. [140°].
Phenyl-hydrazide
 $C_6H_4(C_6H_5Ph)(C_6H_5)_2$. [189°]. Crystals.

Di-*p*-xylyl ethylene diketone
 $C_2H_4(CO.C_6H_4Me_2[2:4:1])_2$. [123°]. Formed from *p*-xylene, succinyl chloride, $AlCl_3$, and CS_2 (Claus). Needles.

***m*-XYLYL ETHYL KETONE**
[1:3:4] $C_6H_4Me_2.CO.C_2H_5$. (239°). Light oil, with aromatic odour, not solid at -10° (Claus, *J. pr.* [2] 43, 140). Yields (1,3,4)-di-methyl-benzoic acid on oxidation.

Phenyl-hydrazide [126°]. Plates, v. sol. hot water, alcohol, and ether.

***p*-Xylyl ethyl ketone**
[4:1:2] $C_6H_4Me_2.GO.C_2H_5$. (238° uncor.). Formed from *p*-xylene, $AlCl_3$, and propionyl chloride (Claus a. Fickert, *B.* 19, 8182). Oil. Oxidised by $KMnO_4$ to $C_6H_4Me_2.CO.CH_2.CO_2H$ [132°] and some (4,1,2)-di-methyl-benzoic acid.

***m*-XYLYL ETHYL KETONE CARBOXYLIC ACID** [4:2:1] $C_6H_4Me_2.CO.CH_2.CH_2.CO_2H$.

Di-methyl-benzoyl-propionic acid. [108°]. Formed from *m*-xylene, succinyl chloride, $AlCl_3$, and CS_2 (Claus, *B.* 20, 1376). Needles, v. sol. hot water, insol. cold.— NH_4A' .— KA' 4aq. V. sol. water.— NaA' 4aq. Needles.— BaA' 3aq. Needles.— PbA' ; white pp.— AgA' : white crystalline pp.

***p*-Xylyl ethyl ketone carboxylic acid**
[4:1:2] $C_6H_4Me_2.CO.CH_2.CH_2.CO_2H$. [84°]. Formed from *p*-xylene in like manner (C). Colourless needles.

XYLYL-DI-ETHYL-PHOSPHINE
 $C_6H_4Me_2.PEt_2$. (266°). Formed by the action of $ZnEt_2$ on $C_6H_4Me_2.PCl_2$ (Czimatia, *B.* 15, 2046). Thick, colourless oil. Yields $B'MeI$ [90°], $B'_2Me.PtCl_6$ [202°], and B'_2EtI [136°].

***m*-XYLYL-GLYOXALINE** $C_6H_4N<\begin{smallmatrix} CH:CH \\ CH:N \end{smallmatrix}$. [32°]. (279°). Formed by the action of HNO_3 on $C_6H_4N<\begin{smallmatrix} CH \\ C(SH):N \end{smallmatrix}$ [192°], which is got by the action of HCl on the product of the action of amido-acetal on *m*-xylyl-thio-urea (Marok-

wald, *B.* 25, 2368). Sl. sol. water.—Aurochloride [165°].—Picrate. [159°]. Yellow needles, m. sol. chloroform.

***o*-XYLYL-GLYOXYLIC ACID**
[4:3:1] $C_6H_4Me_2.CO.CO_2H$. [92°]. Formed by oxidising *o*-xylyl methyl ketone with alkaline K_2FeCy_4 (Buchka a. Irish, *B.* 20, 1766).— BaA' .

***m*-Xylyl-glyoxylic acid**
[4:2:1] $C_6H_4Me_2.CO.CO_2H$. [54°]. Formed by oxidising *m*-xylyl methyl ketone with $KMnO_4$ (Claus, *B.* 19, 231; *J. pr.* [2] 43, 142). Flat prisms. Yields (4,2,1) di-methyl-benzoic acid on boiling with dilute HNO_3 . Gives rise to $C_6H_4.CH(OH).CO_2H$ [119°] on reduction.— CaA' 2aq. Needles.— BaA' 2aq.— AgA' . Needles, sol. hot water.

***p*-Xylyl-glyoxylic acid**
[5:2:1] $C_6H_4Me_2.CO.CO_2H$. [70°–80°]. Formed by oxidation of *p*-xylyl methyl ketone by aqueous $KMnO_4$ (Claus a. Wollner, *B.* 18, 1859). Crystalline, v. sol. alcohol, ether, and $HOAc$, v. sl. sol. water. Splits up above 200° into CO_2 and di-methyl-benzoic aldehyde. Oxidised by HNO_3 to $C_6H_4Me_2.CO_2H$. Ac_2O and $NaOAc$ yield di-methyl-cinnamic acid.— BaA' 6aq; small felted needles.— CaA' 3aq.— AgA' : crystalline pp.

Ethyl ether EtA' . Oil.

XYLYL GLYOXYLIC ALDEHYDE
[1:3:4] $C_6H_4Me_2.CO.CHO$. *Oxim* [95°]. Formed from xylyl methyl ketone, $NaOEt$, and $C_6H_5NO_2$ (Söderbaum, *B.* 25, 3463). Needles (from benzene-ligroin). Acetic anhydride gives the acetyl derivatives of the *syn*-oxim $C_6H_4Me_2.CO.CH:NOAc$ [54°] decomposed by alkalis with formation of $C_6H_4Me_2.CO_2H$ [126°] and by hot Ac_2O yielding $C_6H_4Me_2.CO.CN$ [47°]. $AcCl$ converts the oxim into $C_6H_4Me_2.C(OH)_2.CH:NOAc$ [142°], whence cold $NaOH$ forms $C_6H_4Me_2.CH(OH).CO_2H$ [103°], while $NaOHAq$ at 50° forms 'xylyl formoin' $C_6H_4Me_2.CO.CH(OH).CO.CO.C_6H_5$ [155°].

DI-XYLYL-GUANIDINE
 $HN:C(NH.C_6H_4[1:2:4])_2$. [158°]. Formed by the action of PbO and alcoholic ammonia on di-xylyl-thio-urea (Hofmann, *B.* 9, 1296). Needles, (from alcohol).

XYLYL-HYDRAZINE
[4:2:1] $C_6H_4Me_2.NH.NH_2$. [85°]. Formed from xylyline by diazotisation followed by reduction with Na_2SO_3 , the resulting $C_6H_4N_2H_2.SO_3Na$ 4aq being then treated with zinc-dust and $HOAc$ (Klauber, *M.* 11, 282). Pale-yellow needles, v. sl. sol. water, v. sol. alcohol. Reduces Fehling's solution on warming. On heating with acetoacetic ether it yields a crystalline body [203°] reduced in alcoholic solution by Na to oxy-xylyl-methyl-pyrazole.

Salt.— $C'HCl$ 2aq. [183°]. Small needles.

Di-*o*-xylyl-hydrazine
[3:2:1] $C_6H_4Me_2.NH.NH.C_6H_4Me_2[1:2:3]$. [141°]. *c-Hydrazo-o-xylene*. Got by heating nitro-*o*-xylene (20 g.) with $NaOH$ (20 g.), alcohol (100 c.c.) and zinc-dust (25 g.), and reducing the product with alcoholic ammonium sulphide (Nörling a. Stricker, *Bl.* [2] 50, 613). White needles, sol. alcohol and ether. Easily oxidised by air.

***u*-Di-*o*-xylyl-hydrazine**
 $N_2H_2(C_6H_4Me_2[1:3:4])_2$. [107°]. Formed by reducing nitro-*o*-xylene with sodium-amalgam (N. a. S.). Yellowish white needles, sol. alcohol.

Di-*m*-xylyl-hydrazine

$N_2H_4(C_6H_4Me_2[1:3:5])_2$. [125°]. Obtained from *s*-nitro-*m*-xylene (N. a. S.). Needles, easily oxidised by air.

***u*-Di-*m*-xylyl-hydrazine**

$N_2H_4(C_6H_4Me_2[1:2:4])_2$. [122°]. Got by warming nitro-*m*-xylene (30 g.) with NaOH (30 g.), zinc-dust (40 g.), and alcohol (250 c.c.) and treating the xylene-azo-xylene so obtained with alcoholic ammonia and H_2S (N. a. S.). White needles, sol. alcohol and ether.

Di-*p*-xylyl-hydrazine

$N_2H_4(C_6H_4Me_2[1:2:5])_2$. [145°]. Formed from nitro-*p*-xylene (N. a. S.). Needles, not affected by air.

XYLYLIC ACID *v.* DI-METHYL-BENZOIC ACID.

α-Xylylic acid *v.* TOLYL-ACETIC ACID.

***p*-XYLYLIDENE-DI-IMINE**

$C_6H_4(CH:NH)_2$ [1:4]. Formed by the action of alcoholic NH_3 or dry NH_3 gas upon terephthalic aldehyde (Oppenheimer, *B.* 19, 576). Glassy brittle crystals. V. sl. sol. alcohol and ether.

DI-XYLYL-KETONE $CO(C_6H_4Me_2)_2$ (c. 340°). Obtained from (*m*?)-xylene, $COCl_2$, and $AlCl_3$ (Ador a. Rilliet, *B.* 11, 399). Liquid, not solid at -60°. Split up by long boiling into H_2O and C_6H_5 .

Di-*p*-xylyl ketone

[2:5:1] $C_6H_4Me_2.CO.C_6H_4Me_2$ [1:2:5]. (327° uncor.). Formed from *p*-xylene, CS_2 , and $COCl_2$ in closed vessels; the yield being 55 p.c. (Elbs, *J. pr.* [2] 35, 481). Oil. Quickly decomposed by distillation into H_2O and (*B.* 2, 1'4')-trimethyl-anthracene [227°]. Reduced by zinc-dust and alcoholic KOH to di-*p*-xylyl-carbinol [181°].

Di-xylyl-tetraketone

$C_6H_4.CO.CO.CO.CO.C_6H_4Me_2$ [4:3:1]. [180°]. Formed by the action of cold HNO_3 (S.G. 1.4) on $C_6H_4.CO.CH(OH).CO.CO.C_6H_4$ (Söderbaum, *B.* 25, 3475). Scarlet needles (from CS_2). On dissolving in HOAc and ppg. by water it yields a dihydrate [100°] $C_{20}H_{12}O_8$.

XYLYL MERCAPTAN $C_6H_4Me_2.SH$. (214°).

S.G. 1.036. Got by treating xylene sulphonic chloride with Zn and dilute H_2SO_4 (Yessell, *Z.* 1865, 360), and also by heating xylyl ethyl xanthate with alcoholic potash (Leuckart, *J. pr.* [2] 41, 192). Liquid. — $Hg(S.C_6H_4)_2$. — $Pb(S.C_6H_4)_2$. Yellow powder.

TRI-*p*-XYLYL-METHANE $CH\{C_6H_4Me_2\}_3$.

[188°]. (above 360°). From di-*p*-xylyl-carbinol, *p*-xylene, and P_2O_5 by boiling for four hours (Elbs, *J. pr.* [2] 35, 484). Crystalline grains (from alcohol), v. sol. ether and benzene.

***o*-XYLYL METHYL KETONE**

[4:3:1] $C_6H_4Me_2.CO.CH_3$. (246°). Formed from *o*-xylene, $AcCl$, and $AlCl_3$ (Claus, *B.* 18, 1856; 19, 232; *J. pr.* 1890, 410). Oil, smelling like coumarin (Armstrong a. Kipping, *C. J.* 63, 81). Yields (4,3,1)-di-methyl-benzoic acid on oxidation. Conc. $HClAq$ forms $C_{10}H_{10}O$ [114°]. P_2O_5 gives a body melting at 165°. Zinc-dust reduces the ketone to $C_6H_4.CH(OH).CH_3$ (257°).

Oxim $C_6H_4.C(NO_2H).CH_3$. [85°]. Prisms

(from dilute alcohol), converted by $AcCl$ into $C_6H_4.C(NO_2Ac).CH_3$ [72°].

Phenylhydrazide. Colourless prisms.

***m*-Xylyl methyl ketone**

[4:2:1] $C_6H_4Me_2.CO.CH_3$. (228°). Formed from *m*-xylene, $AcCl$, and $AlCl_3$ (Claus, *B.* 19, 280).

Obtained also by boiling *m*-xylene with $HOAc$, $ZnCl_2$, and $POCl_3$ (Frey, *J. pr.* [2] 43, 120). Oil, smelling like peppermint. Not condensed by $HClAq$. Yields $C_{10}H_8Br_2O$ [69°]. Reduction by HI yields $C_6H_4Me_2.CH_2.CH_3$ (184°) (Claus, *J. pr.* [2] 45, 380). HNO_3 gives $C_{20}H_{18}N_2O_4$ [108°] (Claus, *J. pr.* [2] 41, 492).

***p*-Xylyl methyl ketone**

[5:2:1] $C_6H_4Me_2.CO.CH_3$. (225° uncor.). S.G. 1.9962. V.D. 4.93. Formed from *p*-xylene, $AcCl$, and $AlCl_3$ (Claus a. Wollner, *B.* 18, 1856). Oil, v. sol. alcohol and ether. Oxidised by cold aqueous $KMnO_4$ to *p*-xylyl-glyoxylic acid. Dilute HNO_3 forms di-methyl-benzoic and methyl-phthalic acids.

Oxim $C_6H_4.C(NO_2H).CH_3$. [58°].

XYLYL METHYL KETONE CARBOXYLIC ACID *v.* METHYL-BENZOYL-ACETIC ACID.**XYLYL-DI-METHYL-PHOSPHINE**

$C_6H_4Me_2.PMe_2$. (230°). Formed from $ZnMe_2$ and $C_6H_4Me_2.PCl_2$ (Czinatis, *B.* 15, 2016). Oil. Unites with CS_2 , forming a compound [115°].

XYLYL-METHYL-THIOHYDANTOIN

[1:3:4] $C_6H_4Me_2.N < \begin{smallmatrix} CO.CH_2 \\ CS.NH \end{smallmatrix}$. [165°]. Formed from xylyl-thiocarbimide and alanine (Markwald, *B.* 24, 3282). Needles, v. sol. alcohol.

XYLYL PENTADECYL KETONE

$C_6H_4Me_2.CO.C_{15}H_{31}$. [37°]. (269° at 15 mm.). Formed from *m*-xylene, palmityl chloride, and $AlCl_3$ (Kraft, *B.* 21, 2269). Small plates, yielding di-methyl-benzoic acid [126°] on oxidation.

XYLYL PHENYLAMYL KETONE

$C_6H_4Me_2.CO.CHPh.C_6H_5$. [91.5°]. Formed by Friedel and Craft's method (Wege, *B.* 24, 3541).

XYLYL-PHENYL- *v.* PHENYL-XYLYL-**TRI-XYLYL PHOSPHATE $PO(OC_6H_4Me_2)_3$.**

The *o*- and *p*- compounds are formed by heating *o*- and *p*-xylenol with $POCl_3$ (Kreysler, *B.* 18, 1702). They are oils, v. sol. ether, alcohol, and benzene.

***m*-XYLYL-PHTHALIDE**

$C_6H_4 < \begin{smallmatrix} CH(C_6H_4Me_2) \\ CO \end{smallmatrix} > O$. [84°]. Got by heating $C_6H_4Me_2.CO.C_6H_4.CO.H$ with zinc and HCl (Gresly, *A.* 234, 237). Needles (from alcohol), sl. sol. benzene.

XYLYL-PROPIONIC ACID

[1:3:4] $C_6H_4Me_2.CH_2.CH_2.CO.H$. [105°]. Formed by saponifying the amide. Silky needles, v. sol. hot water. — BAA_2 6aq. Plates, m. sol. water. — CaA_2 4aq. — AgA_2 . White powder.

Amide $C_6H_4Me_2.CH_2.CO.NH_2$. [107°]. Got by heating the oxim of *m*-xylyl ethyl ketone with yellow ammonium sulphide under pressure (Claus, *J. pr.* [2] 46, 477). Needles, sol. hot water.

m*-XYLYL PROPYL KETONE $C_6H_4Me_2O$ *i.e.

[4:2:1] $C_6H_4Me_2.CO.Pr$. (251°). Formed from *m*-xylene, butyryl chloride and $AlCl_3$ (Claus, *J. pr.* [2] 46, 474). Oil, v. sol. alcohol and ether. Yields *m*-xylyl-glyoxylic acid [54°] on oxidation with $KMnO_4$.

Oxim. Crystals, v. e. sol. alcohol.

p-Xylyl propyl ketone [5:2:1] $C_6H_4Me_2.CO.Pr$. (249°). Formed in like manner from *p*-xylene. Light oil.

Oxim [47°]. Colourless needles.

***o*-Xylyl isopropyl ketone**

[4:3:1] $C_6H_4Me_2.CO.Pr$. (258°). Oil, smelling like

turpentine (Claus, *J. pr.* [2] 46, 484). Yields di-methyl-benzoic acid [163°] on oxidation.

Oxim [68°]. Large prisms.

m-Xylol isopropyl ketone

[4:2:1] $C_6H_3Me_2.CO.Pr.$ (245°). Oil, yielding *m*-xylol-glyoxylic acid on oxidation by $KMnO_4$.

Oxim [97°]. Prisms (from alcohol).

Phenyl-hydrazide [129°]. Crystals.

p-Xylol isopropyl ketone

[5:2:1] $C_6H_3Me_2.CO.Pr.$ (240°). Formed from *p*-xylene, isobutyl chloride, and $AlCl_3$ (Claus, *J. pr.* [2] 46, 484). Oil, smelling like mushrooms.

Oxim [76°]. Plates and prisms.

TETRA-*o*-XYLYL SILICATE $Si(OC_6H_4Me)_4$. (c. 460°). Formed by heating *o*-xlenol with $SiCl_4$, the yield being 85 p.c. of the theoretical amount (Herkorn, *B.* 18, 1691). Large prisms.

Tetra-*m*-xylol silicate $Si(OC_6H_3Me_2)_4$. (453°-457°). Formed, in like manner, from *m*-xlenol. Oil.

***m*-XYLYL THIOCARBIMIDE** C_6H_3NS *i.e.* [4:2:1] $C_6H_3Me_2.N:CS$. Formed from di-xylol-thio-urea and P_2O_5 (Hofmann, *B.* 9, 1295). Crystals. Converted by $PhOEt$ and $AlCl_3$ into $C_6H_3NH.CS.C_6H_4.OEt$ [140°] (Gattermann, *B.* 25, 3530).

XYLYL ETHYL DITHIOCARBONATE

$CS(OEt).SO.C_6H_3Me_2$. Formed from potassium

xanthate and *m*-diaz-o-xylene chloride (Leuckart, *J. pr.* [2] 41, 192). Oil, converted by heating with alcoholic potash into xylol mercaptan (214°).

DI-XYLYL-THIO-UREA

$CS(NH.C_6H_3Me_2[1:2:4])_2$. [153°]. Formed by digesting xylidine with CS_2 as long as H_2S escapes (Hofmann, *B.* 9, 1295). Crystals (from alcohol).

XYLYL-UREA $NH_2.CO.NHC_6H_3Me_2[1:2:4]$. [186°]. Formed from crude xylidine sulphate and potassium cyanate (Genz, *B.* 8, 226). Needles (from alcohol).

s-Xylol-urea $NH_2.CO.NHC_6H_3Me_2[1:3:5]$. [162°] (Frentzel, *C. C.* 1888, 1361).

Di-*s*-xylol-urea $CO(NHC_6H_3Me_2[1:3:5])_2$. [275°] (F.); [251°] (G. a. C.). Formed from *s*-xylidine and $COCl_2$ (F.). Formed also from *m*-xylol cyanate and xylidine (Gattermann a. Cantzler, *B.* 25, 1089). Needles.

Di-*m*-xylol-urea $CO(NH.C_6H_3Me_2[1:2:4])_2$. [263°]. A product of the distillation of *m*-xylol-amido-crotonic acid (Conrad a. Limpach, *B.* 21, 527). Sublimes when melting.

Di-xylol-urea $CO(NHC_6H_3Me_2)_2$. Formed by heating urea (1 pt.) with crude xylidine (3 pts.). Felted needles (from hot alcohol), not melted at 250° (Genz, *B.* 8, 226).

Reference.—METHYL-BENZYL-UREA.

Y

YTTERBIUM. Yb. At. w. c. 173. This name is given to the metal, not yet isolated, of an earth separated by Marignac, in 1878, from crude erbia obtained from *gadolinite* or *euxenite*. The claim of ytterbia to rank as a definite homogeneous compound is not yet satisfactorily established.

The discovery of a new earth in a mineral from Ytterby in Sweden was announced in 1788 by Gadolin; in 1797 Ekeberg confirmed the discovery. The new earth was named *yttria*, and the mineral from which it was obtained was called *gadolinite*. Researches into the nature of yttria were conducted by Berzelius in 1819 (*v. Lehrbuch* [5th ed.] 2), Mosander in 1839 and 1843 (*J. pr.* 30, 27), Scheerer in 1842, Cleve and others. In 1878 Marignac made a careful examination of erbia (*A. Ch.* [6] 14, 247); he fractionally decomposed erbium nitrate by heat, and obtained an earth which he called *ytterbia*. The erbia used by Marignac was pink, and gave, in solution, an absorption spectrum; the new earth was white and showed no absorption spectrum. Nilson (*B.* 12, 554; 13, 1489 [1879-80]) prepared ytterbia, but found a reacting weight for the earth different from that assigned to it by Marignac. By repeated fractional decomposition by heat of the nitrate of ytterbium, Nilson separated another earth which he called scandia (*cf.* SCANDIUM, this vol., p. 181). Nilson (*B.* 13, 1489) in 1879 made a fuller examination of ytterbia, and determined the at. w. of the metal of this earth, and the properties of several salts of the metal. In this memoir Nilson asserted

that *erbia* was separable into seven distinct earths: erbia proper, scandia, terbia, thulia, ytterbia, yttria, and Soret's X (afterwards called holmia). (*cf.* ERBIUM, vol. ii. p. 456; and METALS, RARE, vol. iii. p. 245).

Occurrence.—Along with erbia, scandia, yttria, &c., in very small quantities in a few rare Scandinavian minerals, chiefly in *gadolinite* and *euxenite*. Nilson (*l.c.*) obtained c. 20 g. ytterbia from 6-7 kilos. of the crude earths prepared from c. 15 kilos. *gadolinite*.

Preparation of ytterbia.—Nilson (*B.* 13, 1430) mixed finely powdered *euxenite* or *gadolinite*, c. 400 g. at a time, with four times its weight of $KHSO_4$, fused over a powerful burner, pulverised the fused mass, and thoroughly exhausted with cold water; he ppd. the aqueous solution by ammonia, washed the ppd. hydrated oxides, and dissolved in HNO_3 aq; after boiling the solution for some time and filtering, he ppd. by oxalic acid, washed the pp., dried it, and heated strongly until it was decomposed. The crude earths thus obtained were freed from K_2CO_3 by boiling with water, and were then dissolved in HNO_3 aq; the solution was evaporated to dryness, and the residue was fused until red vapours began to come off. The reddish-yellow, opaque solid was then treated with boiling water, whereby a reddish-yellow pp. was formed, which was filtered off by means of a suction-pump. (This pp. contained oxide of Th, along with oxides of Ce, Fe, and U.) The reddish filtrate was evaporated to dryness, and the solid nitrates thus obtained were partly decomposed by heating, the soluble

(undecomposed) portion removed by solution in water, the residue dissolved in HNO_3Aq , the solution evaporated to dryness, the residue partly decomposed by heating, the undecomposed nitrates were removed by washing with water, the residue was dissolved in HNO_3Aq , and so on. After thirty repetitions of this process a solution was obtained that showed merely a trace of red colour after thirty-five repetitions the solution was quite colourless, and showed only two faint absorption bands, one in the green and the other in the red; after forty repetitions a solution was obtained which gave only the red band; and when the process of partial decomposition by heat had been repeated sixty-eight times a solution in HNO_3Aq was obtained which showed no trace of an absorption spectrum. This solution was saturated with H_2S , the small yellowish-brown pp. of PtS_2 was filtered off, the filtrate was ppd. by pure oxalic acid, the pp. was washed, dried, and decomposed by heating strongly, and pure ytterbia was thus obtained. For a modification of this method of separating ytterbia from accompanying earths *v. Auer von Welsbach (M. 4, 630).*

Atomic weight of ytterbium.—The metal has not been isolated; the at. w. was determined by Nilson (*B. 13, 1433*) by dissolving pure Yb_2O_3 (*v. supra*) in HNO_3Aq , adding a suitable quantity of $\text{H}_2\text{SO}_4\text{Aq}$, evaporating on a water-bath to drive off HNO_3 , then on a sand-bath, and finally over a flame until all free H_2SO_4 was removed, weighing the $\text{Yb}_2(\text{SO}_4)_3$ thus obtained, and analysing it. Nilson dissolved pure Yb_2O_3 in HNO_3Aq , evaporated to dryness, partially decomposed the nitrate by heat, treated with water, &c., as described *supra*, and in this way obtained seven fractions, each of which was converted into sulphate. The results are presented in the following table:—

Weight of Yb_2O_3 taken	Weight of sulphate formed	Pctge. composition of sulphate		Atomic w. of Yb.
		Yb_2O_3	SO_3	
1.0063	1.6186	62.171	37.829	173.21
1.0139	1.6314	62.149	37.851	173.03
.8509	1.3690	62.155	37.845	173.08
.7871	1.1861	62.145	37.855	173.00
1.0005	1.6099	62.147	37.853	173.01
.8090	1.3022	62.126	37.874	172.84
1.0059	1.6189	62.134	37.866	172.91
Mean		62.147	37.853	173.01

Chemical relations of ytterbium.—If Yb is really a homogeneous substance, it must be placed in Series 10 of Group III. in the periodic classification of the elements. This group contains the following elements:

Even series—

2 4 6 8 10 12
B (11) Sc (44) Y (89) La (139) Yb (173) —

Odd series—

3 5 7 9 11
Al (27) Ga (70) In (114) — Tl (204)

A comparison of the position of Yb with the positions of elements placed in Series 10 (*v. table on p. 811 of vol. iii.*) shows that Yb

ought to be decidedly more metallic than B, and somewhat more metallic than Al, Ga, or In; the data, however, are too meagre to allow a detailed comparison to be made. Little is known of the properties of compounds of Yb; but what is known broadly confirms the conclusions drawn from the position of the element in the periodic scheme of classification (*cf. EARTHS, METALS OF THE*, vol. ii. p. 424).

Ytterbium oxide Yb_2O_3 . (*Ytterbiu.*) A very heavy, white, infusible powder; slowly acted on by acids when cold or gently warmed, but readily dissolved by dilute acid solutions when boiling. Solutions in acids are colourless, and show no absorption spectra. The emission spectrum of a solution in HClAq , obtained by help of the spark, shows several lines, the most conspicuous of which have the wave-lengths 6221, 5556, 5476, 5352, and 5334 (*v. Lecoq de Boisbaudran, C. R. 88, 1842*). S.G. 9.175. S.H. $(0^\circ-100^\circ)$.0646 (Nilson, *l.c.*).

Hydrated ytterbium oxide. A white, gelatinous, but heavy pp. obtained by adding NH_3Aq to a solution of a salt of Yb; shrinks much when dried, and absorbs CO_2 from the air. Easily soluble in acids (Nilson, *l.c.*).

Ytterbium salts. Nilson (*l.c.*) prepared an oxalate, an acid selenite, and a sulphate; and Marignac (*C. R. 87, 578*) prepared a formate.

Ytterbium oxalate $\text{Yb}_2(\text{C}_2\text{O}_4)_3$. 10aq. A white, microscopically crystalline powder; insoluble in water, scarcely soluble in dilute acids; unchanged in air; gives up part of its water at 100° . Prepared by adding oxalic acid to a warm solution of the sulphate.

Ytterbium selenite $\text{Yb}_2\text{O}_3 \cdot 4\text{SeO}_3$. 5aq. Obtained by adding $\text{Na}_2\text{SeO}_3\text{Aq}$ to a solution of $\text{Yb}_2(\text{SO}_4)_3$, washing the ppd. normal selenite, dissolving in water containing a large excess of H_2SeO_3 , evaporating nearly to dryness, and washing the residue with water. A white crystalline salt, insoluble in water. Loses $4\text{H}_2\text{O}$ at 100° .

Ytterbium sulphate $\text{Yb}_2(\text{SO}_4)_3$. Prepared by dissolving Yb_2O_3 in HNO_3Aq , adding $\text{H}_2\text{SO}_4\text{Aq}$, evaporating on a water-bath to drive off HNO_3 , then on a sand-bath, and finally over a flame at low redness till all H_2SO_4 is removed. An opaque, white solid. Dissolves in water when a large quantity is added at once; if a little is added much heat is produced, the salt combines with the water, and then dissolves very slowly when more water is added. Decomposed at a red heat, fully at a white heat. S.G. 3.793. S.H. .1039 at 0° to 100° .

A *hydrated sulphate* $\text{Yb}_2(\text{SO}_4)_3 \cdot 8\text{aq}$ was obtained by Nilson in large, white, lustrous prisms by evaporating a solution of $\text{Yb}_2(\text{SO}_4)_3$ in water at a gentle heat. M. M. P. M.

YTTRIUM. Y. At. w. c. 89.6. The name yttrium is given to the metal of an earth obtained from a few rare Swedish minerals. The separation of a new earth from a mineral found at Ytterby, in Sweden, was made by Gadolin in 1788. The existence of the new earth was confirmed in 1797 by Ekeberg, and the earth was called by him *yttria*. Subsequent researches carried on by Berzelius, Mosander, Jocheerer, Berlin, Delafontaine, Popp, Bahr a. Bunsen, Marignac, and others showed that the *yttria* of Gadolin and Ekeberg was a mixture of many oxides (*cf. ERRATA*, vol. ii. p. 456; SCANDIUM, vol.

iv. p. 481; Yttræbrum, this vol. p. 879; and *v. infra*, *Homogeneity of Yttria*).

Occurrence.—About 80 to 85 p.c. of yttria, in combination with SiO_2 , is found in the exceedingly rare Swedish mineral *gadolinite*; some specimens of *orthite* also contain yttria, and the earth has also been found, in combination with Nb_2O_5 and Ta_2C_3 , in specimens of *euxenite*. The oxides that generally accompany yttria in these rare minerals are ceria, didymia, erbia, lanthana, lime, magnesia, soda, and oxide of iron.

Preparation of yttria.—The crude oxides of yttrium, erbium, &c., are separated from *gadolinite* by the method of Bahr a. Bunsen described under *Erbium* (vol. ii. p. 457). Margnac (*A. Ch.* [5], 14, 247) converted the oxides into nitrates, heated the nitrates in a Pt basin until red fumes came off freely; treated the residue with water, and separated the solution, which contained much Yt nitrate, from insoluble basic nitrates of Er, &c. He then evaporated the solution to dryness, heated again until partial decomposition was effected, again treated with water, poured off the solution, evaporated it to dryness, partially decomposed the solid nitrates by heat, and so on. After some hundred repetitions of these processes, approximately pure yttria was obtained. Auer von Welsbach (*M.* 4, 630) separated approximately pure yttria from the crude earths obtained from *gadolinite* by a long-continued series of operations based on the facts (1) that yttrium nitrate is less readily decomposed to basic salts than erbium nitrate when a fairly conc. solution of these nitrates is heated with the oxides of the metals made into a paste with water, and (2) that basic yttrium nitrates dissolve in a solution of the normal nitrates of Y and Er more readily than basic erbium nitrates.

References.—Gadolin (*Crell's Annal.* 1796 [1] 313); Ekeberg (*Scher. J.* 3, 187); Klaproth (*Scher. J.* 5, 531); Vaquelin (*Scher. J.* 5, 552); Berzelius (*Scher. J.* 16, 250, 404; and *Lehrbuch* [5th ed.], 2, 177); Berlin (*P.* 43, 105); Scheerer (*P.* 56, 483); Mosander (*P. M.* 23, 251); Popp (*A.* 131, 179); Delafontaine (*Ar. Sc.* [2] 21, 97; 22, 30; 25, 112; 51, 48; 61, 273); Bahr (*A.* 135, 376); Bahr a. Bunsen (*A.* 187, 1); Cleve a. Höglund (*Bl.* [2] 18, 193, 279); Cleve (*Bl.* [2] 21, 344).

Preparation of yttrium.—The metal has not been obtained pure. Wöhler in 1828 (*P.* 13, 580) obtained impure yttrium by reducing the chloride by sodium. In 1864 Popp (*A.* 131, 179) dissolved yttria in HClAq , added NH_4ClAq , evaporated, separated and dried the double chloride of yttrium and ammonium thus formed, mixed this with Na, the double salt and the Na being arranged in alternate layers, heated the mixture in a closed crucible till action began and then allowed the reaction to proceed; washed the fused mass with water, separated unreduced yttria by levigation, washed the dark-grey powder that remained with water, and then with alcohol, and dried it over H_2SO_4 . In 1890 Winkler (*B.* 23, 787) obtained a black powder that decomposed water by heating yttria and finely-divided Mg in the ratio $\text{Y}_2\text{O}_3:3\text{Mg}$ (*cf.* Yttræ, p. 882). Popp describes yttrium as a dark-grey powder resembling *ferrum redactum*, decomposing cold water slowly and hot water rapidly,

Vol. IV.

easily dissolved by dilute acids, including acetic acid, decomposing boiling KOHAc , and NH_4ClAq at the ordinary temperature, with evolution of H and NH_3 ; the metal burns brilliantly when heated on Pt foil; when heated in O it burns with a very dazzling light.

An examination of the emission spectrum of yttrium was made by Thalén: the most prominent lines observed had the wave-lengths 6191, 6131, 5987, 5971, 5662, 5496, 5402, 5205, 5200, 5088, 4900, 4881, 4854, 4874, and 4809 (*Kongl. Sv. Vetens. Acad. Handl.* 12).

The atomic weight of yttrium was determined by Berzelius, Delafontaine, Popp, Bunsen a. Bahr (*v. supra*, *References*) by analyses of the sulphate, or by transforming yttria into the sulphate; the values varied from 92.2 to 102.3. In 1873 Cleve a. Höglund (*v. B.* 6, 1467) made more accurate determinations by analysing purer specimens of $\text{Y}_2(\text{SO}_4)_3$, and obtained the value 89.6.

Chemical relations of yttrium.—Assuming yttrium to be a homogeneous element with at. w. c. 89, it must be placed in Series 6 of Group III. in the periodic arrangement of the elements. This group contains the earth metals; yttrium is preceded in the even series family by B and Sc, and is succeeded by La and Yb. A consideration of the position given to Y in the periodic classification shows that the element ought to closely resemble the other metals of the earths. Too little is known of the properties of many of the earth metals to allow of a detailed comparison of them one with another. A general account of the relations of these metals will be found in *EARTHS, METALS OF THE* (vol. ii. p. 424).

The homogeneity of yttria.—The properties described as belonging to yttria before 1885 were the properties of a mixture of at least five, and perhaps six, different bodies, according to Crookes (*C. N.* 64, 18, 155). Crookes subjected 'yttria' to a prolonged process of fractionation by ammonia (for a description of this method *v. EARTHS*, vol. ii. p. 423), and he then examined the phosphorescence spectra of various fractions. Crookes concludes that yttrium is a compound, or perhaps a very intimate mixture, of simpler bodies. For details of the phosphorescence spectra of the substances obtained by fractionating 'yttria' *v. METALS, RARE* (vol. iii. p. 248). By thirty-two fractionations of 'yttria' by ppn. with NH_4Aq , followed by twenty-six fractionations by ppn. with oxalic acid, Lecoq de Boisbaudran (*C. R.* 103, 649 [1887]) obtained a white specimen of yttria which gave no phosphorescence spectrum when mixed with lime, and which, when converted into chloride, gave a spark spectrum, showing only the lines of yttrium.

Yttrium, bromide of, $\text{YBr}_3 \cdot 9\text{H}_2\text{O}$. Colourless, very deliquescent tablets; obtained by dissolving Y_2O_3 in HBrAq and concentrating (Cleve, *Bl.* [3] 18, 193). The anhydrous salt is obtained by Duboin (*C. R.* 107, 99, 243) by heating Y_2O_3 to redness on a support of gas-carbon in a current of CO and Br vapour. Very soluble in water or alcohol; insoluble in ether.

Yttrium, chloride of, $\text{YCl}_3 \cdot 6\text{H}_2\text{O}$. Obtained by dissolving yttria in HClAq , evaporating to dryness on a water-bath, dissolving in alcohol, and evaporating over H_2SO_4 (Cleve, *l.c.*). Crystallises in large, colourless, very deliquescent,

rhombic prisms (C., l.c.). The anhydrous compound is formed by heating yttria to redness on a support of gas-carbon in a slow stream of CO and Cl (Duboin, l.c.). By evaporating a solution of yttria in HClAq with addition of NH_4Cl a double compound of YCl_3 and NH_4Cl is obtained; double compounds with KCl and NaCl are formed by fusing the constituent chlorides together. Popp (A. 131, 179) described the double compound $\text{YCl}_3 \cdot 3\text{HgCl}_2 \cdot 9\text{H}_2\text{O}$. Cleve (Bl. [2] 31, 195) described $\text{YCl}_3 \cdot \text{SnCl}_4 \cdot 8\text{H}_2\text{O}$.

Yttrium, fluoride of, $2\text{YF}_3 \cdot \text{H}_2\text{O}$. Obtained as a gelatinous pp. by adding HFAq, or solution of an alkali fluoride, to solution of a salt of yttrium (Cleve, Bl. [2] 18, 193).

Yttrium, iodide of, $(? \text{YI}_3)$. Deliquescent crystals, soluble in alcohol; obtained by evaporating a solution of yttria in HIAq (Berlin, P. 43, 105; no analyses given).

Yttrium, oxides of. Besides yttria, Y_2O_3 , there probably exists another oxide containing more oxygen.

YTTRIA Y_2O_3 . (*Yttrium sesquioxide*.) A hydrate, probably $\text{Y}_2\text{O}_3 \cdot 6\text{H}_2\text{O}$ (Popp, l.c.), is obtained, as a gelatinous pp. closely resembling hydrated alumina, by ppg. the solution of a salt of yttrium by ammonia. The oxide is formed by strongly heating this hydrate; also by decomposing by heat the carbonate, nitrate, or oxalate of yttrium in presence of air. Yttria is described as a heavy, white or almost white powder, S.G. 5.078 (Cleve, l.c.); 5.046 (Nilson a. Pettersson, B. 13, 1459). S.H. $(0^\circ-100^\circ)$ 1026 (N. a. P., l.c.). By heating amorphous yttria with CaCl_2 for some hours, and washing with warm water, Duboin (C. R. 107, 99, 243) obtained highly refractive crystals of Y_2O_3 , scarcely acted on by acids or by fused Na_2CO_3 . Yttria is a markedly basic oxide; it absorbs CO_2 from the air, and decomposes solutions of ammonium salts, giving off NH_3 . Yttria is insoluble in water; it dissolves slowly in cold HClAq, HNO_3Aq , or $\text{H}_2\text{SO}_4\text{Aq}$, but more rapidly on warming. By heating a mixture of yttria and finely-powdered Mg, in the ratio $\text{Y}_2\text{O}_3:3\text{Mg}$, Winkler (B. 23, 787) obtained a black powder which slowly gave off H from cold water, rapidly from hot water, and dissolved in dilute HClAq, with violent evolution of H.

YTTRIUM PEROXIDE. By adding $\text{H}_2\text{O}_2\text{Aq}$ and NH_3Aq to a solution of sulphate or nitrate of yttrium, Cleve (Bl. [2] 43, 53) obtained a white gelatinous pp. to which he gave the composition Y_2O_5 ; but this formula cannot be regarded as final.

Yttrium, salts of. The salts which are formed by replacing the H of acids by yttrium belong to the form Y_2X_n , where $\text{X} = 2\text{ClO}_3, 2\text{NO}_3, \text{SO}_3, \text{SO}_4, \text{CO}_3, \frac{2}{3}\text{PO}_4, \&c.$ Almost all the yttrium salts of oxyacids that have been prepared are normal salts; a basic nitrate, and an acid orthophosphate and selenate, are known. Many of the salts are obtained by dissolving yttria in acids and evaporating; those salts which are insoluble, or but slightly soluble, in water are formed by ppn. from the nitrate or sulphate. The salts formed by ppn. are the *arsenate, borate, carbonate, chromate, iodate and periodate, oxalate, phosphates, selenite and sulphite*; besides these salts, the following salts of oxyacids are known, and are soluble in water: *bromate, chlorate and perchlorate, nitrate, selenate, sulphate, thiosulphate and tungstate*. A few double salts are known; the principal are $\text{Y}_2(\text{CO}_3)_3 \cdot \text{M}_2\text{CO}_3 \cdot x\text{H}_2\text{O}$, $\text{Y}_2(\text{C}_2\text{O}_4)_3 \cdot 3\text{M}_2\text{C}_2\text{O}_4 \cdot x\text{H}_2\text{O}$, and $\text{Y}_2(\text{SO}_4)_3 \cdot m\text{M}_2\text{SO}_4 \cdot x\text{H}_2\text{O}$, where M = an alkali metal. Duboin (C. R. 107, 99, 243) obtained a silicate $\text{Y}_2\text{O}_3 \cdot \text{SiO}_2$ by very strongly heating a mixture of 3 pts. yttria with 30 pts. CaCl_2 , and washing with water. The yttrium salts of oxyacids have been examined, chiefly by Cleve (Bl. [2] 18, 193, 289; 21, 344; v. also Berlin, P. 43, 105; Högbom, Bl. [2] 42, 2; Popp, A. 131, 179).

Yttrium, sulphide of. No compound of yttrium and sulphur has been isolated with certainty. Addition of $(\text{NH}_4)_2\text{SAq}$ or NH_4HSAq to a solution of a salt of yttrium ppts. hydrated oxide. By fusing yttria, S, and an alkali carbonate, and washing the fused mass with water, a yellowish-green solid is obtained that is insoluble in water, but is partly decomposed thereby to hydrated oxide and H_2S ; this solid dissolves in acids, giving off H_2S . The same solid seems to be obtained by strongly heating yttria in H laden with CS_2 . No compound of yttrium and S was obtained by heating yttria with Na_2S_2 . By heating YCl_3 in a stream of H_2S , HCl is given off, and a yellow powder remains, which is decomposed by water, with evolution of much H_2S (v. Popp, A. 131, 179). According to Popp (l.c.), the composition of this substance is Y_2S_3 .

By passing dry H_2S over a mixture of YCl_3 with excess of NaCl, heated to c. 1000° in a boat of gas-carbon, Duboin (C. R. 107, 99, 243) obtained a greenish, crystalline solid, which when washed with water left transparent, greenish lamellæ of the double compound $\text{Y}_2\text{S}_3 \cdot \text{Na}_2\text{S}$. M. M. P. M.

Z

ZANZALOÏN v. ALOÏN.

ZEORIN $\text{C}_{11}\text{H}_{20}\text{O}$. [231°]. Occurs in the ethereal extract from *Zeora sorrida* (Paterno, G. 7, 281, 508). Small pyramids with hexagonal base (from ether-alcohol), v. sl. sol. alcohol and ether, insol. water. Neutral. Not attacked by alkalis or dilute acids.

ZINC. Zn. At. w. c. 65.3 (v. *infra*). Mol. w. c. 65.3 at c. 1400° ; probably the same in solution in Hg (v. *infra*). Melts at 419° (determined by air thermometer; V. Meyer a. Riudle, B. 26, 2443); at 417.57° (determined by platinum thermometer, Callendar a. Griffiths, C. N. 63, 1); for older determinations, giving

m.p. from 340° to 450° , v. Carnelley's *Melting- and Boiling-point Tables* (1, 14). Boils between 980° and 954° (Deville a. Troost, *C. R.* 90, 773); at 930° (Vielle, *C. R.* 94, 720; cf. Troost, *C. R.* 94, 788). S.G. c. 6.9 to 7.2 (v. Schiff, *A.* 107, 59; Kalischer, *B.* 14, 2750; Quincke, *P.* 135, 642; Spring, *B.* 16, 2724). V.D. 3.43 at c. 1400° (Mensching a. v. Meyer, *B.* 19, 8295). S.H. (0° to 100°) .0935 (Bunsen, *P.* 141, 1); (19° to 47°) .0932 (Kopp, *T.* 155, 71; cf. Schüller a. Wartha, *B.* 8, 1016). C.E.; if length of bar at $0^{\circ} = l^{\circ}$, then length at $t^{\circ} = (1 + \beta t)$; if volume at $0^{\circ} = V_0$, then volume at $t^{\circ} = (1 + 3\beta t)$; $\beta = .00002976$ from 0° to 100° (Matthiessen, *P. M.* [4] 32, 472). Heat of fusion for 1 kilo = 28,130 (Person, *A. Ch.* [8] 24, 129). T.C. (Ag = 100) 28.1 (Wiedemann, *P. M.* [4] 19, 243). E.C. (Hg at $0^{\circ} = 1$) 16.1 at 0° , 16.92 at 100° (Benoit, *P. M.* [4] 45, 314); 14.83 at 15° (Kirchoff a. Hausemann, *W.* 13, 406). Chief lines in emission spectrum 6360, 6100, 4924, 4911, 4809, 4722, 4679 (Huggins, *L.* 154, 139; cf. Thälén, *Détermin. des Longueurs d'Ondes Raies Métalliques* [Upsala, 1868]; and Ames, *P. M.* [5] 30, 33); for wave-lengths of lines of high refrangibility v. Hartley a. Adeney (*T.* 1884 [1], 97). Zinc crystallises in tabular hexagonal plates, $a : c = 1.556425$ (Williams a. Burton, *Am.* 11, 219; cf. Stolba, *J. pr.* 89, 122; 96, 178; Sharples, *Am. S.* [3] 7, 223; Nöggerath, *P.* 39, 324; Nicklès, *A. Ch.* [3] 22, 37; G. Rose, *B.* 1852. 26; *P.* 107, 448; Storer, *P. Am. A.* 6; Cooke, *Am. S.* 31, 191). The metal is probably dimorphous. H.O. [Zn, O] = 85,430 (Thomsen, *Th.* 8, 275). Refraction equivalent = 9.8 (Gladstone, *Pr.* 18, 49).

Historical.—That copper acquired a reddish colour, and that its properties were modified, by melting with certain ores, was known to the ancients and the alchemists; the ore with which copper was generally melted to form brass was called *cadmia fossilis*. The fact that a lustrous solid could be obtained by heating *cadmia fossilis* seems to have been known to the ancient writers on mineralogy. According to Kopp (*Geschichte der Chemie*, 4, 116), the earliest use of the word *zinc* is found in a writing of the fifteenth century attributed to Basil Valentine. Paracelsus, in the sixteenth century, speaks of zinc as a definite metal-like substance, and assigns it to the class of bastard or semi-metals. The name 'zinc' was applied during the seventeenth and eighteenth centuries alike to zinc ores and to the metal-like substance obtained from these ores. Boyle speaks of zinc, and also uses the word *spelter*, or *spiauter*, a term of Indian origin according to Kopp. Tolerably pure zinc seems to have been obtained from zinc ores about 1720; probably by Henckel (v. Percy's *Metallurgy*, 1, 520).

Occurrence.—Zinc is found in small quantities; Becker (*J. M.* 1857. 698), and Phigson (*C.* R. 55, 218) noticed the occurrence of native zinc in Victoria. Considerable quantities of compounds of zinc occur in many places; the commonest ores are *calamine* (carbonate), *siliceous calamine* (silicate), *blende* (sulphide), and *red zinc ore* (oxide); aluminate, arsenat., phosphate, and sulphate of zinc are also found, but in smaller quantities. Small quantities of Cd compounds occur in most zinc ores. The

ash of a plant that grows on the waste heaps of the zinc works in Rhenish Prussia (*Viola calaminaria*) is said to contain compounds of zinc (Braun, *P.* 92, 175). Zinc compounds have been found in some springs (v. Hillebrand, *U. S. Geol. Survey Bull.* No. 113 [1893]). Traces of zinc compounds have been found, according to Lechartier a. Bellamy (*C. R.* 84, 687), in the human liver, in calves' liver, in beef, hens' eggs, wheat, barley, maize, beans, and vetches.

Formation.—Zinc ore, generally carbonate or sulphide, is roasted in reverberatory calciners; the roasted ore is mixed with half its weight of powdered charcoal, coke, or anthracite, and heated in crucibles or retorts arranged so that the reduced metal distils from the impurities; the metal is condensed and collected in suitable vessels, and CO passes off. For details and descriptions of the different forms of apparatus v. *DICTIONARY OF APPLIED CHEMISTRY*, vol. iii. p. 1042.

Preparation.—Commercial zinc generally contains from .5 to 3.3 p.c. lead, with c. .2 to .5 p.c. iron and cadmium, and small traces of arsenic.

Pure zinc was prepared by Reynolds a. Ramsay (*C. J.* 51, 854 [1887]) by dissolving zinc sold as free from common impurities in dilute H_2SO_4 Aq, evaporating, crystallising the sulphate several times, electrolysing a solution of this salt, the metal being deposited on an electrode of Pt wire, dissolving the metal in dilute HCl Aq, ppg. ZnO_2H_2 by NH_4 Aq, dissolving the pp. in excess of NH_4 Aq, and ppg. ZnS by H_2S ; the ZnS was dissolved in HCl Aq, and again ppd. from an ammoniacal solution by H_2S ; the pp. was well washed, dissolved in pure dilute H_2SO_4 Aq, and the sulphate obtained on crystallisation was re-crystallised several times; an aqueous solution of this sulphate was then electrolysed, using a Pt wire as electrode, and the metal was melted in a tube of hard glass from which the air had been exhausted. By distilling this metal *in vacuo* in a tube of hard glass, very pure zinc was obtained. Pulinger (*C. J.* 57, 816 [1890]) distilled zinc sold as 'chemically pure' in a hard glass tube, bent slightly towards the closed end, placed in a combustion furnace, the open end being connected with a good water-pump. By melting the distilled zinc in a tube of hard glass with a small bulb blown on the end, the part of the tube between the bulb and the wider portion containing the zinc being capillary, and the open end being connected with a water-pump, he obtained the zinc in perfectly bright, smooth, lustrous spheres free from hollows; the pump was stopped while the zinc was molten, and the increased pressure caused the molten metal to filter through the capillary tube into the bulb. For the preparation of pure zinc by electrolysis of an ammoniacal solution of the sulphate, v. Myers (*C. R.* 74, 195).

Stolba (*C. C.* 1884. 419) says that zinc can be obtained free from As and nearly free from iron by the combined interaction of S and water vapour. He mixes burnt gypsum with one-fourth its weight of S powder, moulds the moistened mixture into spheres about 5 cm. diameter, and sinks these to the bottom of a crucible containing molten zinc; vapours of

H₂S and S are given off, and the molten metal is thereby briskly agitated. When the reaction is completed, the little balls are taken out, the upper crust is removed, and the operation is repeated if necessary.

Zinc-dust is obtained either in the distillation of the metal, or, in not such fine division, by crushing and powdering the metal in an iron mortar at a temperature somewhat below the m.p. of zinc. The ZnO₂H₂ always present in specimens of zinc-dust may be removed by digesting with NH₄ClAq and then with NH₄Aq, and drying on a porous tile *in vacuo* (Carnegie, C. J. 53, 471).

Properties.—Zinc is a white metal, with a slight shade of blue; it is very lustrous when polished. Commercial zinc is brittle at the ordinary temperature, but it becomes malleable between 100° and 150°; at 210° it again becomes brittle, and at that temperature it can be finely powdered in a mortar. Pure zinc is said to be malleable at the ordinary temperature. Commercial zinc that has been heated to 100°–150° retains its malleability when it cools. Kahlischer (B. 14, 2747) noticed that rolled zinc ceased to give a ringing sound when struck after it was heated to c. 160°–300°, that it could then be bent easily, and that when bent it emitted a sound like the 'cry' of tin; he found that the zinc became crystalline, and the crystalline structure was more decided the higher the temperature; the S.G. was very slightly increased, and the electrical resistance was reduced by c. 8 p.c. Zinc is a softer metal than copper; its hardness is increased by rolling. The tensile strength of zinc varies much with the mode of preparation. Zinc crystallises easily, especially when pure; the form is that of hexagonal plates (for references *v. supra*, beginning of this article). Zinc melts at c. 420°, and boils somewhat below 1000° (*v. supra*). Molten zinc expands somewhat during solidification. The metal can be distilled at a full red heat; the vapour takes fire in the air, and burns with formation of ZnO and the production of a bright white light. Zinc exposed to the ordinary air becomes very gradually covered with a thin film of a basic carbonate which protects the mass of the metal from further corrosion; in pure dry air zinc is unchanged. Zinc dissolves in dilute acids, generally with evolution of H (*v. infra*, *Reactions with sulphuric and nitric acids*); it also dissolves in solutions of caustic potash or soda. When impure zinc is amalgamated it resists the action of acids. Zinc is not acted on by mineral lubricating oils; some of the commoner animal oils attack it slightly (*v. Redwood, C. S. I. 5, 862*). Zinc ppts. most of the other metals from their solutions; if a piece of impure zinc is dissolved in an acid, most of the metallic impurities (As, Cd, Cu, Pb, &c.) remain undissolved as long as undissolved zinc is present. Zinc combines directly with O, S, Se, Te, the halogens, and P; it forms alloys with many metals. Pure zinc does not decompose boiling water, but the commercial metal reacts and gives off H. Zinc-dust usually contains some ZnO₂H₂; it is said also to contain H₂, produced by the interaction of Zn and ZnO₂H₂ (*v. Greville Williams, C. N. 52, 205, 268*).

Atomic and molecular weights of zinc. In 1809 Gay-Lussac (*Mém. S. d'A., 2, 174*) deter-

mined the weight of ZnO obtained by dissolving a determinate weight of zinc in nitric acid, evaporating to dryness, and strongly heating the residue; Berzelius in 1811 repeated the experiment of Gay-Lussac (G. A. 37, 400; *v. also P. 8, 184*); and in 1843 Erdmann made similar experiments (*v. Berzelius' Lehrbuch, 3, 1219*). The values obtained for the at. w. of zinc were 65.39 (G.-L.), 65.41 (B.), and 64.94 and 64.88 (E.). In 1844 Favre decomposed ZnC₂O₄ by heating in air, and determined the weights of ZnO and CO₂ produced; the value 65.85 was thus obtained for the at. w. of zinc. In the same year Favre obtained the value 65.78 by dissolving zinc in dilute H₂SO₄Aq, burning the H given off by passing it over hot CuO, and weighing the water thus produced (*A. Ch. [3] 10, 168*). In 1884 Marignac determined the Cl and the Zn in ZnCl₂.2KCl, and obtained the value 65.18 for the at. w. of zinc (*A. Ch. [6] 1, 509*; *v. also* Baubigny, C. R. 97, 908 [1883]). By dissolving zinc in dilute H₂SO₄Aq and measuring the H given off, van der Plaats concluded that the at. w. of zinc is 65.18 (C. R. 100, 52 [1885]). Reynolds a. Ramsay, in 1887, by measuring the H given off by the interaction between very pure zinc and H₂SO₄Aq, obtained the value 65.43 (C. J. 51, 854). By oxidising zinc to ZnO, by HNO₃Aq, in 1888, Morse a. Burton obtained the value 65.18 (*Am. 10, 811*). In 1889 Gladstone a. Hibbert (C. J. 55, 448) determined the ratio of zinc dissolved to silver deposited by one and the same electric current; taking the at. w. of silver as 107.66 (the value adopted in this *Dictionary*) the at. w. of zinc was found to be 65.29.

In 1886 Mensching a. V. Meyer (B. 19, 3295) found the V.D. of zinc at c. 1400° to be 34.3, a number which shows that the gaseous molecule of zinc is monatomic. Ramsay, in 1889, determined the lowering of the vapour pressure of Hg produced by dissolving zinc therein (C. J. 55, 521); assuming that equal volumes of dilute solutions contain equal numbers of molecules, and that the molecular weight of liquid Hg is 200, Ramsay's results indicate that the molecules of zinc in dilute solutions of this metal in Hg are monatomic. The experiments of Heycock a. Neville (C. J. 57, 376 [1890], and 61, 888 [1892]) on the lowering of the freezing-points of Bi, Cd, Pb, Sn, and Na by solution of zinc in these metals tend to confirm the conclusion that the molecule of zinc in dilute solutions in these metals is monatomic.

Chemical relations of zinc. Zinc is the second odd-series member of Group II. in the periodic classification of the elements. Zinc is preceded in the odd series of this group by Mg and is followed by Cd, —, and Hg; the members of the even series of Group II. are Be, Ca, Sr, Ba, —, —. Zinc is the second member of series 5; it is preceded in this series by Cu, and is succeeded by Ga, Ge, As, Se, and Br. The general chemical character of zinc—that of a metal; its oxide ZnO is basic, its chloride ZnCl₂ is volatilisable without decomposition. No acids are known containing zinc, and the molecule of the element is monatomic. The fact that compounds of ZnO and K₂O are obtained by dissolving ZnO₂H₂ in KOHAq and adding alcohol shows that the hydroxide of the metal has feebly marked acidic properties, and the 'isola-

tion of a number of oxychlorides and basic carbonates, nitrates, and sulphates illustrates the fact that zinc is less positive than Mg, which is the first member of the zinc family of Group II. For a general account of the properties of the family of which zinc forms a member v. MAGNESIUM GR UP OF ELEMENTS, vol. iii. p. 163. The atom of zinc is divalent in the gaseous molecules of its compounds.

Reactions and Combinations.—1. Zinc is unchanged in pure dry air; in ordinary air the surface layers are slowly converted into a basic carbonate, which protects the metal beneath. Heated strongly in air or oxygen, zinc burns to ZnO.—2. Heating zinc in bromine, chlorine, or iodine produces ZnBr_2 , ZnCl_2 , or ZnI_2 .—3. When zinc is heated in phosphorus vapour, phosphide of zinc (q. v., p. 890) is formed.—4. By heating zinc with selenium vapour, a compound of Zn and Se is formed (v. ZINC SELENIDE, p. 890).—5. Zinc combines with tellurium when the elements are heated together (v. ZINC TELLURIDE, p. 891).—6. Sulphur and zinc combine when a mixture of these elements is very strongly compressed (Spring, B. 16, 1000).—7. Zinc decomposes water at a red heat. Commercial samples of zinc decompose water at 100° (L'Hôte, C. R. 101, 1153).—8. ZnS is formed by strongly heating zinc in a stream of hydrogen sulphide; when hydrogen selenide is used the product is ZnSe, and by heating the metal in hydrogen telluride ZnTe is formed (v. Margottet, C. R. 84, 1293).—9. Zinc is said to reduce carbon monoxide at a very high temperature.—10. Zinc is superficially oxidised by heating to dull redness in nitric oxide (Sabatier a. Senderens, C. R. 114, 1429). Oxidation in nitrogen dioxide (NO_2) is effected at 800° (S. a. S., C. R. 115, 236).—11. Many metallic oxides are reduced by heating with zinc.—12. Zinc reacts with sulphurous acid solution; according to Schweizer (v. C. N. 23, 293), the products are ZnSO_4 , along with $\text{H}_2\text{S}_2\text{O}_4$, $\text{H}_2\text{S}_3\text{O}_4$, and S.—13. Zinc dissolves in hydrochloric acid, giving off H and forming ZnCl_2 . Reynolds a. Ramsay (C. J. 51, 857) say that pure zinc scarcely reacts with boiling hydrochloric acid. For reactions of zinc with sulphuric and nitric acids, v. *infra*.—14. Zinc dissolves slowly in hot solutions of caustic soda or potash, giving off H, and forming $\text{ZnO} \cdot x\text{M}_2\text{O}$ (cf. ZINC HYDROXIDE, p. 888); the reaction is much hastened by adding iron or Pt along with the zinc.—15. Many metallic salts in solution are reduced by zinc, with ppn. of the metals, e.g. salts of As, Cd, Cu, and Pb.—16. When zinc dust is shaken with an aqueous solution of ferric chloride, the whole of the ferric salt is very rapidly reduced to ferrous chloride (for details of the application of this reaction in the estimation of ferric iron, v. Carnegie, C. J. 53, 468 [1888]).—17. According to Siersch (J. 1867, 257), zinc dissolves in sodium chloride solution, forming $\text{ZnCl}_2 \cdot 2\text{NaCl}$, ZnO , and H.—18. Poumarède (J. pr. 73, 496) says that nearly all chlorides and fluorides are reduced by reacting with vapour of zinc in an atmosphere of H.—19. By heating to redness a mixture of zinc filings and sodium metaphosphate, Hyvlel (A. 100, 99) probably obtained phosphides of zinc (v. ZINC PHOSPHIDES, p. 890).—20. Zinc reacts with sodium hydrogen sulphite solution,

forming ZnSO_4 , $\text{Na}_2\text{S}_2\text{O}_4$, and Na_2SO_4 (v. HYPOSULPHITES, this vol. p. 692).—21. By heating zinc with zinc sulphide in an exhausted tube, some of the ZnS is carried forward and deposited in the front part of the tube; probably at a high temperature ZnS is decomposed, and there exist only Zn and S, and at a lower temperature these recombine to form ZnS (Morse a. White, Am. 11, 848). A similar phenomenon is noticed on heating zinc with zinc oxide (M. a. W., l.c. p. 258).—22. ZnS is formed by strongly heating zinc and mercuric sulphide or zinc and potassium polysulphides (v. ZINC SULPHIDE, p. 890).

When slips of zinc-foil are immersed in CuSO_4 , a deposit of finely-divided Cu is formed on the zinc. This copper-zinc couple is an energetic reducing agent; KClO_4 is reduced to KCl , KNO_3 to KNO_2 and NH_3 , K_2FeCy_4 to K_2FeCy_3 , SO_4 to S , As_2O_3 to AsH_3 , $\text{C}_6\text{H}_5\text{NO}_2$ (in alcohol) to $\text{C}_6\text{H}_5\text{NH}_2$, &c. (v. Gladstone a. Tribe, C. J. 33, 306).

Reactions of zinc with sulphuric and nitric acids. Commercial zinc dissolves easily in dilute H_2SO_4 , with formation of ZnSO_4 and evolution of H. In 1830 De la Rive noticed that very little action took place between approximately pure zinc and H_2SO_4 ; this fact has been confirmed by other experimenters. Reynolds a. Ramsay (C. J. 51, 857 [1887]) found that zinc prepared by repeated electrolysis of the sulphate and distillation *in vacuo* scarcely reacted with H_2SO_4 ; L'Hôte (C. R. 101, 1153) also asserted that pure zinc does not react with H_2SO_4 . Divers a. Shimidzu (C. J. 47, 598 [1885]) observed very great differences between the rate of action of the same H_2SO_4 on sheets of commercial zinc of the same size. Pullinger in 1890 (C. J. 57, 815), and Weeren in 1891 (B. 24, 1785), made somewhat elaborate investigations into the connections between the conditions and the rate of the interaction of zinc and H_2SO_4 .

Pullinger used 'pure' sulphuric acid diluted with three times its weight of water; and zinc prepared by distilling that sold as 'chemically pure' *in vacuo* and casting in balls under pressure to prevent the formation of cracks or hollows (v. *supra*, Preparation of zinc, p. 885). He found that when the surface of the zinc was very smooth—this was best accomplished by immersing in *aqua regia* for 10 or 15 seconds, and washing with water—and the acid was boiled for some hours before the experiment, there was practically no reaction at 20° – 25° (spheres of zinc weighing c. 2½ g. lost from 5 to 6 mgms. in 20 hours). Pullinger found that the presence of small quantities of H_2S , SO_2 , or $\text{H}_2\text{S}_2\text{O}_4$ did not affect the weight of zinc dissolved by the boiled H_2SO_4 ; addition of some H_2O_2 materially increased the rate of action; and H_2SO_4 that had been electrolysed before use dissolved from four to ten times more zinc than some of the same acid that had not been electrolysed; addition of a few drops of HNO_3 considerably increased the action; when a few drops of HCl were added to the H_2SO_4 practically no action occurred. P. supposed that all the 'pure' acid used by him contained traces of an oxidising substance, probably $\text{H}_2\text{S}_2\text{O}_8$, and that the solvent action was due to this. P.

insists on the important connection between the rate of action and the smoothness or roughness of the surface of the zinc used. But he concludes that 'in all probability pure dilute sulphuric acid would, at ordinary temperatures, be entirely without action upon metallic zinc, whether the surface of the latter were rough or smooth.'

Weeren used zinc which he found to be chemically pure by analysis; he gives no account of his method of preparation nor any details of his analytical results. W. found that the weight of pure zinc dissolved by pure $\text{H}_2\text{SO}_4\text{Aq}$ (1:20) at the ordinary temperature, and under a pressure of 10 mm., was c. ten times greater than the weight dissolved at 760 mm. pressure; but the weights of impure zinc dissolved at the two pressures were almost the same. The pure zinc used by W. dissolved fairly rapidly in boiling $\text{H}_2\text{SO}_4\text{Aq}$; in one case when 2.1 mgm. dissolved at 0° after thirty minutes' action, 122 mgm. dissolved in the boiling acid. W. found that the solubility of his pure zinc increased very slowly as temperature rose up to within 1° of the b.p. of the acid used, but that when ebullition actually began the solubility of the zinc suddenly increased; the weight of pure zinc dissolved by $\text{H}_2\text{SO}_4\text{Aq}$ at 100° and boiling, was c. sixteen times greater than the weight of the same zinc dissolved by the same acid at 100° but kept from actually boiling by pressure. On the other hand, W. noticed that as much impure zinc dissolved at 100° when the acid was boiling as when it was prevented by pressure from boiling. Addition of oxidisers, CrO_3 or H_2O_2 , enormously increased (c. 300 times) the solubility of pure zinc in $\text{H}_2\text{SO}_4\text{Aq}$ at 18° - 20° , but only slightly increased (c. six times) the solubility of impure zinc. W. supposes that when pure zinc is immersed in pure $\text{H}_2\text{SO}_4\text{Aq}$ a slight reaction occurs, and that the H produced is attracted to and held firmly on the surface of the zinc, and that the reaction ceases because the surface of the metal is protected by the layer of H. Increase of temperature does not appreciably affect the rate of action, because the layer of H remains fixed to the surface of the zinc, but when the acid boils the H is removed and rapid dissolution occurs; any conditions which remove the layer of H increase the solubility of the zinc. W. supposes that the rate of dissolution of impure zinc in $\text{H}_2\text{SO}_4\text{Aq}$ is not much affected by boiling, presence of oxidisers, &c., because H is not given off at the surface of the zinc, but at the surface of the more negative impurities. The rapid solution of zinc in HNO_3Aq is connected, according to W., with the rapid oxidation of the H produced at the surface of the zinc, and hence the production of a layer of water on the surface of the metal which destroys the attraction between the zinc and any H that may escape oxidation.

As regards the products of the interaction of zinc and sulphuric acid, when the acid is fairly concentrated (c. $\text{H}_2\text{SO}_4\cdot\text{H}_2\text{O}$ to c. H_2SO_4) SO_2 is given off, and at moderately high temperatures H_2S and S are also produced (v. Calvert & Johnson, *C. J.* [2] 4, 435 [1867]). A qualitative examination of the products by Pattison Muir & Adie (*C. J.* 53, 47 [1888]) showed that ZnSO_4 is the only salt of zinc produced, with any concen-

tration of acid, and at any temperature up to the b.p. of the acid used; that with approximately pure zinc little or no SO_2 or H_2S is formed unless the temperature be high; and that the purer the zinc the less is the quantity of S produced (cf. Ditte, *A. Ch.* [6] 19, 68).

The products of the interaction of zinc and nitric acid are $\text{Zn}(\text{NO}_3)_2\text{Aq}$, $\text{Zn}(\text{NO}_3)_2\text{Aq}$, $\text{NH}_4\text{NO}_3\text{Aq}$ and $\text{NH}_4\text{NO}_2\text{Aq}$, and NO , N_2O , and N . Acworth found that when HNC_2Aq reacts with zinc in presence of $(\text{NH}_4)_2\text{NO}_3$, the chief gaseous product is N (along with some N_2O and NO) (*C. J.* 28, 828 [1875]). Acworth & Armstrong studied the reaction of HNO_3Aq and Zn more fully in 1878 (*C. J.* 32, 5c.), and found that the only gaseous products were N , N_2O , and NO (cf. Deville, *C. R.* 70, 22, 550 [1870]). According to Divers (*C. J.* 43, 443 [1883]), a little $\text{NF}_3\cdot\text{OH}$ is formed when cold HNO_3Aq (8 to 4 p.c.) is poured on to granulated zinc and quickly poured off again. Divers & Shmidzu (*C. J.* 47, 597 [1885]) found that considerable quantities of NH_4OH are produced by the combined reaction of HNO_3Aq and $\text{H}_2\text{SO}_4\text{Aq}$, or HNO_3Aq and HClAq , on zinc (v. Hydroxylamine, *Formation*, vol. ii. p. 734). Divers (*l.c.*) thought that zinc does not form $\text{Zn}(\text{NO}_3)_2$ by a direct reaction with HNO_3Aq , but by interacting with some of the $\text{Zn}(\text{NO}_3)_2$ formed by the primary action of the metal on the acid. The products of the interaction of zinc and HNO_3Aq have been examined recently by Montemartini (*G.* 22 [1], 277 [1892]), who says that free H is not produced (he also says that no NH_4OH is formed), and that in addition to nitrate and nitrite of zinc and ammonium, hyponitrite is also produced; the gaseous products, according to M., are N_2O , NO , NO_2 , and N ; there is no nitrous acid formed, says M., if the HNO_3Aq contains more than 30 p.c. HNO_3 , and no NO_2 if less than 30 p.c. HNO_3 is present. M. also gives determinations of the quantities of the various products at different temperatures, and of the rate of reaction with different concentrations of HNO_3Aq (*Abstract in C. J.* 62, 1279 [1892]).

Zinc, alloys of. Alloys of zinc have been formed with most metals by fusing the constituents together; the alloys are generally hard, some of them are brittle. With *antimony*, two crystalline alloys are formed by melting the metals together, in the ratios $3\text{Zn}:2\text{Sb}$ and $\text{Zn}:\text{Sb}$, and allowing to cool very slowly; Cooke (*Am. S.* [2] 18, 229; 20, 222) formulates these alloys as Zn_3Sb_2 and Zn_2Sb , respectively. These alloys react with water and give off H. Alloys with *arsenic* are formed by heating together Zn and As, or Zn and As_2O_3 , or by heating Zn in vapour of As and H; by the last method Descamps (*C. R.* 86, 1022, 1065) obtained crystals agreeing in composition with the formula Zn_2As_3 . Spring (*B.* 16, 324) formed an alloy by compressing Zn and As, in the ratio $8\text{Zn}:2\text{As}$, at 6,500 atmospheres. Zinc alloys with *osmium* when the metals are melted together, but on cooling two layers are formed, the upper containing zinc with c. 2 p.c. Bi, and the lower Bi with from 8 to 14 p.c. zinc. An alloy of zinc with *bismuth* and *lead* (3 pts. Zn, 5 pts. Bi, and 5 pts. Pb) melts at 94.5° . For descriptions of alloys with *calcium* v. Caron (*C. R.* 48, 440; 50, 547); Wöhler (*A.* 138, 253); and Norton & Twitchell

(*Am. J.* 10, 70). Brass is composed of alloys of zinc with copper (*v.* vol. ii. p. 254; and for details *v.* DICTIONARY OF APPLIED CHEMISTRY, vol. iii. p. 1052). Alloys of zinc with copper and nickel form German silver; most modern bronzes are alloys of zinc with copper and tin (*v.* vol. ii. p. 254; and for details *v.* DICTIONARY OF APPLIED CHEMISTRY, vol. iii. p. 838). Zinc alloys with iron (for details *v.* DICTIONARY OF APPLIED CHEMISTRY, vol. iii. p. 1051). For alloys with lead *v.* vol. iii. p. 125 (also Krant, *S. C. I.* 5, 537). Alloys with lead and tin are mentioned in vol. iii. p. 125 (*v.* also Wright a. Thompson, *Pr.* 48, 25). For alloys with magnesium *v.* Parkinson (*J. pr.* 101, 375). Zinc and mercury form a number of amalgams, which are brittle when a little Hg is present and pasty when much Hg is present (for references *v.* *S. C. I.* 9, 512). For alloys with platinum *v.* this vol. p. 288. For alloys with silver *v.* Wright a. Thompson (*Pr.* 48, 25).

For an account of the formation of zinc alloys by immersing zinc in various metallic solutions *v.* Mylius a. Fromm (*B.* 27, 630 [1894]).

Zinc, amide of, $\text{Zn}(\text{NH}_2)_2$. This compound was obtained by Frankland (*Pr.* 8, 502) by passing dry NH_3 into an ethereal solution of ZnEt_2 . A white, amorphous powder; unchanged at 200° , but decomposed at a red heat to Zn_3N_2 (*v.* ZINC NITRIDE, p. 889) and NH_3 ; reacts with water to form ZnO , H_2 , and NH_3 .

Zinc, bromide of, ZnBr_2 . Formula probably molecular, from analogy of ZnCl_2 . S.G. 3.643 at 10° (Bödeker). Melts at 394° (Carnelley, *C. J.* 33, 277). Boils at 695° to 699° (C. a. Williams, *C. J.* 33, 283); at 650° (Freyer a. V. Meyer, *B.* 25, 622). H.F. [Zn, Br^2] = 75,930 (*Th.* 3, 275).

Preparation.—1. Zinc filings are heated to dull redness in a stream of Br vapour.—2. Zinc, or ZnO , H_2 , is dissolved in a slight excess of HBrAq , the solution is evaporated to dryness, and the dry residue is sublimed out of contact with air.

Properties and Reactions.—White needles; very deliquescent. Easily soluble in water, alcohol, or ether (*v.* Berthelot, *J. Ph.* 14, 610). Thomsen gives [ZnBr_2, Aq] = 15,030 (*Th.* 3, 275). Aqueous solutions of ZnBr_2 of different concentrations have the following specific gravities according to Kremers (*P.* 108, 115):—

S.G. ZnBr_2, Aq at 19.5° .	P.c. ZnBr_2 .
1.1949	18.3
1.3519	31.7
1.5276	43.2
1.7082	52.6
1.8525	59.1
2.1027	68.0

Combinations.—1. With ammonia to form a series of compounds. These compounds were examined by Rammelsberg (*P.* 55, 240), and, more recently, by André (*Bl.* [2] 39, 398 [1888]). By dissolving ZnBr_2 in NH_3Aq under different conditions, A. obtained (1) $\text{ZnBr}_2 \cdot 2\text{NH}_3 \cdot \text{H}_2\text{O}$, (2) $3\text{ZnBr}_2 \cdot 8\text{NH}_3 \cdot 2\text{H}_2\text{O}$, (3) $3\text{ZnBr}_2 \cdot 10\text{NH}_3 \cdot \text{H}_2\text{O}$, and (4) $\text{ZnBr}_2 \cdot 5\text{NH}_3$; by saturating hot NH_3BrAq with ZnO , he obtained $3\text{ZnBr}_2 \cdot 6\text{NH}_3 \cdot \text{H}_2\text{O}$.—2. With caesium bromide, to form $\text{ZnBr}_2 \cdot 8\text{CsBr}$ and $\text{ZnBr}_2 \cdot 2\text{CsBr}$ (Wells a. Campbell, *Zeit. f. anorg. Chemie*, 5, 273).

Zinc, chloride of, ZnCl_2 . Mol. w. c. 136. Melts at 262° (Braun, *P.* 154, 190). Boils at 708° – 719° (Carnelley a. Williams, *C. J.* 33, 284); at 730° (Freyer a. V. Meyer, *B.* 25, 622). S.G. 2.753 at 13° (Bödeker). V.D. at 890° to 907° = 66 (F. a. M., l.c.). H.F. [Zn, Cl^2] = 97,210 (*Th.* 3, 275).

Formation.—1. By heating zinc filings in Cl_2 .—2. By heating a mixture of 2 pts. HgCl_2 and 1 pt. zinc filings in a retort.—3. By distilling a mixture of equal pts. ZnSO_4 and CaCl_2 , or a mixture of 1 pt. ZnO and 2 pts. NH_4Cl .—4. By dissolving zinc, or ZnO , H_2 , in HClAq , evaporating to dryness, and heating the residue in a retort.

Preparation.—1. Zinc filings are heated in a small retort in a stream of Cl_2 ; the product is distilled.—2. Zinc, or ZnO , H_2 , is dissolved in a slight excess of HClAq ; the solution is evaporated to dryness, and the residue is distilled from a small retort.

Properties and Reactions.—A white, semi-transparent, crystalline, very caustic solid; very deliquescent. Easily soluble in water, also in alcohol. Thomsen gives [ZnCl_2, Aq] = 15,630 (*Th.* 3, 275). Sublimes at a red heat. An aqueous solution is partly decomposed on evaporation, giving oxychlorides (*q.v.*). Oxychlorides are also formed by heating a solution of ZnCl_2 in HClAq with ZnO , also with HgO or PbO . Kremers (*P.* 105, 360) gives the following data:

S.G. ZnCl_2, Aq	P.c. ZnCl_2
1.1275	13.8
1.2466	25.8
1.3869	37.5
1.5551	49.2

A conc. solution of ZnCl_2 is often used as a bath for maintaining fairly high constant temperatures. Dry ZnCl_2 is used as a caustic; also as a dehydrating agent; a dilute aqueous solution is employed as an antiseptic.

Combinations.—1. With water. By keeping ZnCl_2Aq containing 70.5 p.c. ZnCl_2 at 0° for 24 hours, Engel (*C. R.* 102, 111) obtained large crystals of the trihydrate, $\text{ZnCl}_2 \cdot 3\text{H}_2\text{O}$, melting at 7° . When ZnCl_2Aq containing 79.9 p.c. ZnCl_2 at 0° is kept for a long time it solidifies; on heating to 16° a part melts and a part remains solid; the liquid part is the dihydrate $\text{ZnCl}_2 \cdot 2\text{H}_2\text{O}$, and the solid part is the hydrate $2\text{ZnCl}_2 \cdot 3\text{H}_2\text{O}$ (E., l.c.). By heating a syrupy solution of ZnCl_2 with a little HClAq , Schindler (*Mag. Pharm.* 36, 45) obtained octahedral crystals of the monohydrate $\text{ZnCl}_2 \cdot \text{H}_2\text{O}$. According to Engel (l.c.), the hydrate obtained by S. was $2\text{ZnCl}_2 \cdot 3\text{H}_2\text{O}$.—2. With hydrogen chloride and water. Engel (*M.* 5, 432) obtained the compounds $2\text{ZnCl}_2 \cdot \text{HCl} \cdot 2\text{H}_2\text{O}$ and $\text{ZnCl}_2 \cdot \text{HCl} \cdot 2\text{H}_2\text{O}$ by passing HCl gas into ZnCl_2Aq , and adding zinc from time to time, and, when the solution had the S.G. of 2.0, cooling to 0° .—3. Various compounds of ZnCl_2 with ammonia have been described; the formulæ $\text{ZnCl}_2 \cdot \text{NH}_3$, $\text{ZnCl}_2 \cdot 2\text{NH}_3$, $2(\text{ZnCl}_2 \cdot 2\text{NH}_3) \cdot \text{H}_2\text{O}$, $\text{ZnCl}_2 \cdot 4\text{NH}_3 \cdot \text{H}_2\text{O}$, and $\text{ZnCl}_2 \cdot 5\text{NH}_3 \cdot \text{H}_2\text{O}$ have been given to compounds obtained by dissolving ZnCl_2 in NH_3Aq , passing in NH_3 , and evaporating under different conditions (*v.* Marignac, *Ann. M.* [5] 12, 1; Divers, *C. N.* 18, 18; Priwosnik, *P.* 142, 467; Davis, *C. N.* 25, 265; André, *A. Ch.* [6] 3, 84, 98; Thoms, *B.* 30,

748).—4. Lang (*B.* 21, 1578) described a compound with pyridine, $\text{ZnCl}_2 \cdot 2\text{C}_5\text{H}_5\text{N}$.—5. ZnCl_2 combines with alkali chlorides. Compounds, $\text{ZnCl}_2 \cdot \text{NH}_4\text{Cl} \cdot x\text{H}_2\text{O}$, $\text{ZnCl}_2 \cdot 2\text{NH}_4\text{Cl} \cdot x\text{H}_2\text{O}$, and $\text{ZnCl}_2 \cdot 8\text{NH}_4\text{Cl}$ are described by Schindler (*Mag. Pharm.* 36, 45), Marignac (*J.* 1857, 217), Rammeisberg (*P.* 94, 508), and Hantz (*A.* 66, 287). A compound $\text{ZnCl}_2 \cdot 2\text{KCl}$ is described by R. (*l.c.*) and M. (*l.c.*); and a compound $\text{ZnCl}_2 \cdot 2\text{NaCl} \cdot 3\text{H}_2\text{O}$ by M. (*l.c.*). Wells and Campbell (*Zeit. f. anorg. Chemie*, 5, 273) describe two compounds with CsCl , to which they give the formulæ $\text{ZnCl}_2 \cdot 2\text{CsCl}$ and $\text{ZnCl}_2 \cdot 3\text{CsCl}$.—6. With *sinc oxide*, v. *Oxychlorides*, p. 891.

A solution of zinc in conc. HClAq , to which as much NH_4Cl has been added as the weight of zinc dissolved, is used for cleaning the surfaces of metals that are to be soldered together; any oxide on the metallic surfaces reacts with the NH_4Cl present to form chloride which dissolves in the ZnCl_2 solution.

Zinc, cyanide of, and double zinc cyanides; v. vol. ii. p. 347. For details regarding the conditions of formation and the properties of *sinc-mercuric cyanide*, v. Dunstan, *C. J.* 61, 666 [1892].

Zinc, ferrocyanide of; v. vol. ii. p. 337.

Zinc, fluoride of, ZnF_2 . Formula probably molecular, from analogy of ZnCl_2 . Formed by heating zinc or ZnO to redness in a stream of dry HF ; also by the interaction of fused ZnCl_2 and dry HF at 800° to 900° ; also by heating the hydrated salt to redness in dry HF (Pouleno, *C. R.* 116, 581 [1893]). The *tetrahydrate* $\text{ZnF}_2 \cdot 4\text{H}_2\text{O}$ is obtained by evaporating a solution of zinc in HFAq , and crystallising. The salt ZnF_2 crystallises in colourless needles, probably monoclinic. S.G. 4.84 at 15° ; the crystals act strongly on polarised light (P., *l.c.*). Clarke (*Am. S.* [3] 13, 291) gives S.G. of ZnF_2 as 4.556 at 17° , and 4.612 at 12° ; and the S.G. of $\text{ZnF}_2 \cdot 4\text{H}_2\text{O}$ as 2.567 at 10° and 2.535 at 12° . ZnF_2 is slightly soluble in cold, more soluble in hot, water; it is insoluble in alcohol at 95° ; soluble in boiling HClAq , $\text{H}_2\text{SO}_4\text{Aq}$, or HNO_3Aq (P., *l.c.*). Heated in air, or to redness in steam, it is wholly changed to ZnO ; fusion with alkali carbonates produces ZnO and alkali fluorides; heating with H_2S forms ZnS , and with HCl forms ZnCl_2 . It is reduced by H at a red heat (P., *l.c.*). ZnF_2 forms *double salts* with AlF_3 and with alkali fluorides. Berzelius (*P.* 1, 26) described the salts $\text{ZnF}_2 \cdot 2\text{AlF}_3$ and $\text{ZnF}_2 \cdot 2\text{KF}$; and Wagner (*B.* 19, 896) the salts $\text{ZnF}_2 \cdot 2\text{NH}_4\text{F} \cdot 2\text{aq}$, $\text{ZnF}_2 \cdot \text{KF}$, and $\text{ZnF}_2 \cdot \text{NaF}$. The compound $\text{ZnF}_2 \cdot \text{ZrF}_2 \cdot 6\text{aq}$ ($= \text{ZnZrF}_6 \cdot 6\text{aq}$) is described by Marignac (*A. Ch.* [3] 60, 257); S.G. 2.255 at 12° (Topsøe, *C. C.* 4, 76). For $\text{ZnF}_2 \cdot \text{SiF}_4$, v. *Zinc silicofluoride*, p. 890.

Zinc, hydrophosphide of, ZnPH . A white, friable solid having this composition was obtained by Drechsel and Finkelstein (*B.* 4, 352) by passing dry PH_3 into a cooled ethereal solution of ZnEt_2 . The compound can be kept in a closed vessel; in air it absorbs moisture and rapidly decomposes, giving off PH_3 .

Zinc, hydrosulphide of. According to Thomsen (*B.* 11, 2044 [1878]), the pp. obtained by mixing NaHSaAq and ZnSO_4Aq in equivalent quantities, is probably a hydrosulphide of zinc (no analyses or formula given). Addition of

two equivalents of NaSH in solution to an equivalent of ZnSO_4 in solution produces no pp., but the solution gives a pp. of ZnS or hydrosulphide on standing, or on addition of acid or soda (T., *l.c.*). According to von Zotta (*M.* 10, 807 [1890]), the pp. supposed by Thomsen to be zinc hydrosulphide has the composition $\text{ZnS} \cdot \text{H}_2 \cdot 2\text{ZnS}$. When four equivalents of NaSH are added to one equivalent of ZnSO_4 , both in solution, and the clear solution is boiled, or treated with acid or alkali, a pp. of $\text{ZnS} \cdot \text{H}_2 \cdot 2\text{ZnS}$ is obtained (von Z., *l.c.*). Linder and Picton (*C. J.* 61, 130 [1892]) obtained evidence in favour of the existence of compounds of Zn , S , and H , probably $7\text{ZnS} \cdot \text{H}_2 \cdot \text{S}$ and $12\text{ZnS} \cdot \text{H}_2 \cdot \text{S}$, by passing H_2S into water at 0° with $\text{ZnO} \cdot \text{H}_2$ in suspension; they failed to isolate a definite compound with certainty.

Zinc, hydroxide of, $\text{ZnO} \cdot \text{H}_2$. (*Zinc hydrate. Hydrated zinc oxide.*) Obtained, as a white flocculent pp., by adding to solution of a salt of zinc rather less KOHaAq than is sufficient to decompose the whole of the salt, washing thoroughly, and drying at a low temperature. According to Ville (*C. R.* 101, 875), $\text{ZnO} \cdot \text{H}_2$ is obtained in crystals by shaking very finely-powdered ZnCO_3 , or basic carbonate, with twice as much KOH in 10 p.c. solution as is theoretically required for the decomposition of the carbonate; formation of crystals of $\text{ZnO} \cdot \text{H}_2$ begins at once, and is complete after twenty to thirty minutes. $\text{ZnO} \cdot \text{H}_2$ is said to be obtained in lustrous rhombic prisms by immersing zinc in contact with iron or copper in NH_4Aq (Nioklès, *A. Ch.* [3] 22, 31; Cornu, *Bl.* 5, 64 [1863]). Bødker (*A.* 94, 358) obtained the *monohydrated hydroxide* $\text{ZnO} \cdot \text{H}_2 \cdot \text{H}_2\text{O}$ in very lustrous octahedra by keeping a saturated solution of the hydroxide in NaOHAq in a closed vessel for some weeks. S.G. of $\text{ZnO} \cdot \text{H}_2$ is given by Nioklès (*l.c.*) as 2.677, and by Filhol (*A. Ch.* [3] 21, 415) as 3.058. Thomsen gives $[\text{ZnO} \cdot \text{H}_2 \cdot \text{O}] = 82,680$ (*Th.* 3, 276). $\text{ZnO} \cdot \text{H}_2$ dissolves easily in acids, forming salts ZnX_2 .

$\text{ZnO} \cdot \text{H}_2$ also dissolves in caustic alkali solutions, and in $(\text{NH}_4)_2\text{CO}_3\text{Aq}$. By adding alcohol to a solution of $\text{ZnO} \cdot \text{H}_2$ in KOHaAq , Laux (*A.* 9, 183) obtained small lustrous crystals ($2\text{ZnO} \cdot \text{K}_2$); Fremy (*C. R.* 15, 1106) obtained (?) $\text{ZnO} \cdot \text{K}_2 \cdot \text{ZnO}$; by using NaOHAq Comey and Jackson (*B.* 21, 1589 [1888]) obtained two compounds derived from $\text{ZnO} \cdot \text{H}_2$ by replacing H by Na . They shook a solution of $\text{ZnO} \cdot \text{H}_2$ in conc. NaOHAq with alcohol, separated the upper (alcoholic) layer and allowed it to crystallise, and treated the lower (watery) layer repeatedly with alcohol until it solidified. The crystals from the lower layer had the composition

$\text{Zn}_2\text{O}_2\text{Na}_2\text{H}_2 \cdot 17\text{H}_2\text{O}$ ($= \text{Zn}_2(\text{OH})_2(\text{ONa})_2 \cdot 17\text{H}_2\text{O}$), agreeing, except in water of crystallisation, with an ammonium compound described by Malaguti (*C. R.* 62, 413 [1866]); this compound melts at c. 70° , rapidly absorbs CO_2 from the air, loses $12\text{H}_2\text{O}$ at 100° , is insol. in ether, and is decomposed by water, but not in presence of excess of NaOH , with formation of ZnO and a little $\text{ZnO} \cdot \text{H}_2$. The crystals from the upper layer had the composition

$\text{ZnO} \cdot \text{NaH} \cdot 7\text{H}_2\text{O} = (2\text{Zn}(\text{OH})(\text{ONa}) \cdot 7\text{H}_2\text{O})$, corresponding with the compound described by Fremy (*l.c.*); this compound forms white radiating needles, which do not melt at 300° ; it

absorbs CO_2 from the air more slowly than the other compound, is decomposed by alcohol or water, and does not lose H_2O until heated above 200° (*v. Am.* 11, 145 [1889]). C. a. J. failed to obtain compounds derived from ZnO_2H_2 by replacing H by NH_4 or Mg. Compounds of ZnO with BaO , CrO , and MgO are described by Bertrand (*C. R.* 115, 989); these compounds are of the forms $2\text{ZnO} \cdot \text{MO} \cdot x\text{H}_2\text{O}$.

Zinc, iodide of, ZnI_2 . Formula probably molecular, from analogy of ZnCl_2 . Formed by heating together zinc and iodine, and subliming; also by digesting I with water and excess of zinc until the liquid is colourless and evaporating over H_2SO_4 (Rammelsberg, *P.* 43, 665). Crystallises in white octahedra; S.G. 4.696 (Bödeker); melts at $c. 446^\circ$ (Carnelley, *C. J.* 33, 278); and boils at $c. 674^\circ$ (O. a. Williams, *v. Carnelley's Melting- and Boiling-point Tables*, 1, 23). H.F. $[\text{ZnI}_2] = 49,230$; $[\text{ZnI}_2\text{Aq}] = 60,540$ (*Th.* 3, 275). Heated in air ZnI_2 gives off I, and ZnO remains. Kremers (*P.* 111, 61) gives the following data:—

S.G. ZnI_2Aq	P.c. ZnI_2	S.G. ZnI_2Aq	P.c. ZnI_2
1.2340	23.1	1.9746	63.5
1.5121	42.6	2.8976	76.0
1.7871	56.3		

Hot ZnI_2Aq is said to dissolve zinc in contact with the air, and on filtering an oxyiodide is said to be deposited (Müller, *J. pr.* 26, 441). ZnI_2Aq also dissolves I; Baup (*J. Ph.* 9, 37 [1823]) says enough I is dissolved to form ZnI_4 .

ZnI_2 combines with NH_3 . By allowing a solution of ZnI_2 in NH_3Aq to evaporate, Rammelsberg (*P.* 43, 152) obtained lustrous, four-sided prisms of $\text{ZnI}_2 \cdot 4\text{NH}_3$, decomposed by water with production of ZnO . Various double compounds with other iodides have been described: $\text{ZnI}_2 \cdot 2\text{MI}$, where $\text{M} = \text{NH}_4$, K or Na (Rammelsberg, *l.c.*; also *P.* 43, 665); $\text{ZnI}_2 \cdot 2\text{CsI}$ and $\text{ZnI}_2 \cdot 3\text{CsI}$ (Wells a. Campbell, *Zeit. f. anorg. Chemie*, 5, 273); $2\text{ZnI}_2 \cdot \text{BaI}_2$ (*R., l.c.*); $\text{ZnI}_2 \cdot 2\text{BiI}_3$, 12aq (Linau, *P.* 111, 240).

Zinc, nitride of, Zn_3N_2 . Obtained by Frankland (*Fr.* 8, 502) by heating zinc amide ($\text{Zn}(\text{NH}_2)_2$; *v. p.* 887) to low redness. A grey, pulverulent solid; unchanged by heating to redness out of contact with air; reacts violently with water to give $\text{ZnO} \cdot \text{H}_2$ and NH_3 .

Zinc, nitroprusside of, *v. vol. ii. p.* 341.

Zinc, oxides of. Besides the normal basic oxide ZnO , there seems to be another higher (? superoxide) of zinc.

Zinc oxide ZnO . Formula not certainly molecular.

Occurrence.—With oxides of Mn, and Fe, as red zinc ore and franklinite.

Formation.—1. By burning zinc in air or O_2 . 2. By strongly heating ZnO_2H_2 , $\text{Zn}(\text{NO}_3)_2$, ZnCO_3 , or another salt of zinc with a volatilisable anion.

Preparation.—Pure ZnSO_4 , prepared as described under Zinc, Preparation (*p.* 883), is dissolved in water, and the solution is very slowly added to a boiling solution of pure Na_2CO_3 , containing rather less Na_2CO_3 than suffices to decompose all the ZnSO_4 . The pp. of basic zinc carbonate is washed by decantation with boiling water until the washings are free from carbonates

and sulphates; it is then dried, powdered, and heated either in a Hessian crucible, or, better, in a flask of hard glass, until a portion taken from the middle dissolves, when cold, in acid without effervescence. The solid is now finely powdered, sifted through a fine sieve, again heated, and then rubbed up with water, and washed and dried. ZnO is prepared in crystals by heating ZnCl_2 to redness in steam (Daubrée, *C. R.* 39, 153); also by heating the amorphous oxide slowly in a stream of H (Regnault, *A. Ch.* [2] 62, 350; Deville, *A. Ch.* [3] 43, 477); also by heating the amorphous oxide to whiteness in a stream of O (Sidot, *C. R.* 69, 202); also by heating $\text{Zn}(\text{NO}_3)_2$ to redness (Brügelmann, *W.* 4, 283).

Properties.—A slightly yellow, powdery solid; becomes darker yellow when heated, but recovers its original colour on cooling. S.G. 5.5 to 5.7 (*v. Brügelmann, B.* 13, 1741; Fülhol, *A. Ch.* [3] 21, 415; Herapath, *C. J.* 1, 42; Karsten, *S.* 65, 394). S.G. crystalline (at 15°) 5.782 (Brügelmann, *W.* 4, 286). ZnO crystallises in slightly yellow, lustrous, hemimorphous pyramids belonging to the hexagonal system (*B., l.c.*). Thomsen (*Th.* 3, 275) gives H.F. $[\text{ZnO}] = 85,430$. Richards a. Rogers (*Am.* 15, 567 [1893]) found that ZnO , prepared by heating $\text{Zn}(\text{NO}_3)_2$, gave off some gas when dissolved in dilute acids; the maximum amount of gas from 10 g. ZnO was 20 c.c.; the gas consisted chiefly of N, with a little O; the higher the temperature to which the $\text{Zn}(\text{NO}_3)_2$ had been heated the less was the quantity of gas obtained; but some N always came off, even from ZnO which had been heated to the softening temperature of porcelain. Moissan (*C. R.* 115, 1034 [1893]) states that ZnO volatilises readily when heated in an electric furnace, and condenses again in transparent crystals. ZnO is not decomposed at $c. 1750^\circ$ (Read, *C. J.* 65, 313 [1894]).

Reactions and Combinations.—1. ZnO is a basic oxide. It interacts with most acids to form salts ZnX ($\text{X} = 2\text{NO}_3$, SO_4 , $\frac{2}{3}\text{PO}_4$, &c.) and water.—2. With fairly conc. caustic soda or potash, salts are formed which are most simply regarded as derived from ZnO_2H_2 , with H replaced by Na or K (*v. Zinc hydroxide, p.* 888).—3. ZnO is reduced to Zn, with explosive violence, by heating with magnesium (*v. Winkler, B.* 23, 128).—4. Morse a. White (*Am.* 11, 258) heated a mixture of ZnO and zinc in an exhausted tube, and found that a deposit of ZnO formed in the front part of the tube. They suppose that some of the original ZnO is decomposed by the combined action of heat and zinc, and that zinc and O exist together in the hot part of the tube, but combine in the cooler parts of the tube to form ZnO .—5. Oxychlorides, oxybromides, and probably oxyiodides of zinc are formed by heating ZnO with zinc chloride, bromide, and iodide respectively.—6. ZnO is reduced to zinc by heating with carbon or in carbon monoxide.—7. ZnO does not directly interact with water; $\text{ZnO} \cdot \text{H}_2$ is produced by ppg. a zinc salt solution by an alkali (*v. Zinc hydroxide, p.* 888).—8. By heating ZnO with oxides of aluminium, chromium, and iron along with B_2O_3 in a pottery furnace until the B_2O_3 was volatilised, Ebelmen (*A. Ch.* [3] 38, 34) obtained the compounds $\text{ZnO} \cdot \text{Al}_2\text{O}_3$, $\text{ZnO} \cdot \text{Cr}_2\text{O}_3$, and $\text{ZnO} \cdot \text{Fe}_2\text{O}_3$.

ZINC PEROXIDE. In 1818 Thénard (*A. Ch.* [2] 9, 55) obtained what he called 'deutoxide de zinc' by the action of H_2O_2 on gelatinous $\text{ZnO}_2\cdot\text{H}_2$, and also by adding KOH to a solution of $\text{ZnO}_2\cdot\text{H}_2$ in HCl to which H_2O_2 had been added. In 1884 Haas (*B.* 17, 2249) obtained a white, tasteless, neutral, gelatinous pp. by adding H_2O_2 to solutions of zinc salts and then adding NH_4Aq ; after washing and drying at 100° , the solids had approximately the compositions Zn_2O_3 and Zn_3O_4 . H. thinks it probable that the substances obtained by him were compounds of ZnO and ZnO_2 ; the formula $2\text{ZnO}\cdot3\text{ZnO}_2$ agrees well with some of his analyses.

Zinc, oxybromides of. Oxybromides of zinc are formed by heating solutions of ZnBr_2 with ZnO , and by partially ppg. ZnBr_2 by NH_4Aq . Several compounds have been described by André (*Bl.* [2] 39, 398 [1884]):

(1) $\text{ZnBr}_2\cdot4\text{ZnO}\cdot x\text{H}_2\text{O}$, $x = 10, 13$, and 19 ;

(2) $\text{ZnBr}_2\cdot5\text{ZnO}\cdot6\text{H}_2\text{O}$; (3) $\text{ZnBr}_2\cdot6\text{ZnO}\cdot35\text{H}_2\text{O}$.

Zinc, oxychlorides of. These compounds are formed by adding to ZnCl_2 a quantity of NH_4Aq less than sufficient for complete ppg.; also by boiling ZnCl_2 with ZnO , or with certain other metallic oxides. Schindler (*Mag. Pharm.* 36, 45) obtained $\text{ZnCl}_2\cdot3\text{ZnO}\cdot4\text{H}_2\text{O}$ by boiling ZnCl_2 with ZnO , and the same compound by partially ppg. ZnCl_2 by NH_4Aq . By adding to ZnCl_2 so much NH_4Aq that the pp. which formed at first partly dissolved, and also by treating $\text{ZnCl}_2\cdot4\text{NH}_3$ with water, Kane (*A. Ch.* 72, 296) obtained $\text{ZnCl}_2\cdot6\text{ZnO}\cdot10\text{H}_2\text{O}$. André (*C. R.* 106, 854) obtained $2\text{ZnCl}_2\cdot3\text{ZnO}\cdot11\text{H}_2\text{O}$ by boiling ZnCl_2 with HgO and letting the solution cool; using PbO he obtained another oxychloride, probably $\text{ZnCl}_2\cdot3\text{ZnO}$, combined with $\text{ZnCl}_2\cdot\text{PbO}$.

Zinc, oxyiodides of. According to Müller (*J. pr.* 26, 441 [1842]), ZnI_2 dissolves zinc when warmed therewith in the air; on cooling, an oxyiodide, $\text{ZnI}_2\cdot3\text{ZnO}\cdot2\text{aq}$, is ppd.

Zinc, oxysulphides of. The compound $4\text{ZnS}\cdot\text{ZnO}$ occurs native as *voltzite*, as spherical globules in some specimens of *galena*. A compound having the same composition was found in a furnace flue at Freiberg by Karsten (*S.* 57, 186). By heating dry ZnSO_4 to redness in H , Arfvedson obtained a yellow-coloured oxysulphide $\text{ZnS}\cdot\text{ZnO}$ (*P.* 1, 59).

Zinc, perbromoplatinocyanide of. v. vol. ii. p. 845.

Zinc, phosphides of. Zinc and P combine when heated together, forming a greyish, lustrous, somewhat malleable compound. By heating finely powdered zinc in vapour of P, Schrötter obtained a compound, with S.G. 4.76, having the composition Zn_3P_2 (*W. A. B.* 1859, 301). Vigier obtained the same compound by heating zinc in H until distillation began, and then passing H laden with vapour of P over the zinc. The same compound was formed by Regnault (*A. Ch.* [4] 9, 162) by heating to whiteness a mixture of MgHPO_4 , ZnS and C; along with the Zn_3P_2 were formed crystals of another phosphide, probably ZnP ; and by treating Zn_3P_2 with dilute acid, an amorphous, yellow solid remained which detonated when mixed with KClO_4 , and struck, and which was perhaps ZnP_2 . The compound Zn_3P_2 was obtained by

Hvoslef (*A.* 100, 99) by strongly heating a mixture of ZnO , P_2O_5 , and C. By heating a mixture of NaPO_3 and zinc shavings in a retort, H. (*l.c.*) obtained a yellowish red, loose sublimate which contained Zn and P; and by heating the fused mass in the retort with HCl aq, grey lustrous tablets of ZnP_2 remained. Lüpke (*C. C.* 1890 [ii.] 642) formed zinc phosphide (ZnP_2) by adding amorphous P to molten zinc covered with $(\text{NH}_4)_2\text{CO}_3$; this phosphide was not decomposed by water, but was slowly decomposed by dilute HCl aq, giving off PH_3 .

For the compound ZnP_2 v. **ZINC HYDROPHOSPHIDE**, p. 888.

Zinc, platino-cyanide of. v. vol. ii. p. 844.

Zinc, salts of. Many salts are obtained by replacing the H of acids by zinc. The greater number of the salts of zinc are normal salts; several basic carbonates, nitrates, and sulphates are known. The following are the chief salts of zinc derived from oxyacids:—*Arsenite and arsenate, borate, bromate, carbonates, chlorate and perchlorate, chromates, iodate and periodate, molybdates, nitrates and nitrites, phosphates and phosphites, selenate and selenite, silicate, sulphates and sulphite, thiosulphate, tungstates, vanadates* (v. **CARBONATES, NITRATES, SULPHATES, &c.**).

Zinc, selenide of. ZnSe . This compound is formed, in reddish-yellow, regular crystals, S.G. 5.40, by heating zinc to redness in a stream of H_2Se , and then subliming in a slow stream of H (Margottet, *C. R.* 84, 1293).

Zinc, selenocyanide of. v. vol. ii. p. 848.

Zinc, silicofluoride of. $\text{ZnSiF}_6\cdot6\text{H}_2\text{O}$. Obtained in hexagonal plates, easily sol. in water, by evaporating to a small bulk a solution of ZnO in H_2SiF_6 aq (Berzelius). S.G. 2.104 (Topsøe, *C. C.* 4, 76).

Zinc, stannifluoride of. $\text{ZnSnF}_6\cdot6\text{H}_2\text{O}$; v. this vol., p. 724.

Zinc, sulphocyanide of. v. vol. ii. p. 358.

Zinc, sulphide of. ZnS . This compound is not formed by heating together zinc and S, as the S volatilises before the temperature of combination is reached.

Occurrence.—As *zinc blende*.

Preparation.—1. By repeatedly subjecting a mixture of zinc and S, in the ratio $\text{Zn:S} = 2$, to a great pressure; the product resembled zinc blende (Spring, *B.* 16, 1,000).—2. By rapidly heating a mixture of zinc filings and cinnabar in a retort; formation of ZnS occurs with detonation; Hg distils off.—3. By heating ZnO with S.—4. By heating ZnO , or $\text{ZnO}\cdot\text{H}_2$, in a stream of H_2S ; in the case of $\text{ZnO}\cdot\text{H}_2$, formation of ZnS takes place very slowly (v. Wagner, *D. P. J.* 197, 334).—5. ZnS is also formed by heating dry ZnSO_4 with S and C.—6. ZnS is obtained by passing H_2S into a neutral or alkaline solution of a zinc salt, or into a solution in a weak acid, such as acetic acid, washing the pp., drying it at 100° , and heating in a stream of H_2 . The pp. dried at 100° is said to be $2\text{ZnS}\cdot\text{H}_2\text{O}$ (Geiger a. Reimann, *Mag. Pharm.* 81, 178; cf. Souhay, *Fr.* 7, 78).

Properties and Reactions.—S.G. of $\text{ZnS} = 3.93$ (Karsten, *S.* 65, 394); S.G. of *blende* = 4.08 to 4.07 (v. Neumann, *P.* 23, 1). Thomsen (*Th.* 3, 276) gives H.F. of $\text{ZnS}\cdot x\text{H}_2\text{O}$ as $[\text{Zn}_3\text{S}_2\cdot x\text{H}_2\text{O}] = 41,580$. ZnS prepared by ppg. is a yellowish

solid; easily sol. in acid, forming salts of Zn and giving off H_2S . Zinc blende is a grey to black crystalline solid; slowly acted on by acids. By repeatedly washing $ppd.$ ZnS, also by passing H_2S into water containing pure $ZnO.H_2$ in suspension, Winkinger (*Bl.* [2] 49, 462 [1888]) obtained colloidal γnS , sol. in water; the solution could be boiled until all excess of H_2S was expelled without $ppn.$ of ZnS. ZnS prepared by adding excess of NH_4Aq to $ZnCl_2Aq$, $ppg.$ all the zinc as ZnS by H_2S , washing and drying the $pp.$, and then heating nearly to whiteness in a Hessian crucible inside a plumbago crucible, is very phosphorescent (*v.* Henry, *C. R.* 115, 503).

By heating Zn^4 with zinc in a vacuum tube, Morse a. White (*Am.* 11, 348) found that some of the ZnS was carried forward and deposited on the cooler part of the tube; they supposed that some of the ZnS was decomposed, and that Zn and S existed in the hottest part of the tube and combined in the cooler portions. By heating blende with I and a little water some $ZnSO_4$ is formed (Fihol a. Melhies, *A. Ch.* [4] 22, 58; Lasaulx, *J.* 1870, 1272).

According to Schiff (*A.* 115, 74), a *polysulphide of zinc*, probably ZnS_3 , is formed by $ppg.$ a neutral solution of a salt of zinc by K_2S_2Aq , and drying the $pp.$ over H_2SO_4 . Spring (*B.* 16, 1000) thought that a polysulphide of zinc was probably formed by strongly compressing a mixture of zinc with excess of S.

Zinc, telluride of, $ZnTe$. Obtained, in large ruby-red, regular crystals, by strongly heating zinc in a stream of H_2Te , and then subliming in a slow current of H (Margottet, *C. R.* 84, 1293).

Zinc, titanifluoride of, $ZnTiF_6$; *v.* this vol., p. 742. M. M. P. M.

ZINC, ORGANIC COMPOUNDS OF.

Zinc methyl or Zinc methide $CnZnMe$, *i.e.* $ZnMe_n$. Mol. w. 95. V.D. 3.29 (calc. 3.30). $[-40^\circ]$ (Haase, *B.* 26, 1053). (46°) . S.G. $\frac{195}{1.886}$.

Formation.—1. By heating methyl iodide with zinc in sealed tubes at 150° . The compound $IZnMe$ is formed as an intermediate product. The reaction takes place more easily when the MeI is mixed with two-thirds of its volume of ether and heated to 100° , but it is then difficult to separate the ether from the $ZnMe_2$ (Frankland, *A.* 85, 346; 111, 62; Wanklyn, *C. J.* 13, 124; Butlerow, *A.* 144, 2; Ladenburg, *A.* 173, 147).—2. By heating finely granulated zinc with $HgMe$, in a sealed tube for 24 hours at 120° , and distilling the product (Frankland a. Duppa, *C. J.* 17, 80).—3. $IZnMe$ is formed in 24 hours if MeI is left in contact with a large amount of copper-zinc couple (Gladstone, *C. J.* 35, 109).

Preparation.—Zinc filings (9 pts.) are heated with reduced copper (1 pt.) till the copper-zinc couple is produced, and the product treated with MeI (Gladstone, *C. J.* 35, 569).

Properties.—Colourless mobile liquid, taking fire on exposure to air. Decomposed by water into CH_4 and $Zn(OH)_2$. By very careful oxidation it appears to yield $Zn(OMe)_2$ and crystalline $ZnMe(OMe)$, which is split up by water into $Zn(OH)_2$, methyl alcohol, and CH_4 .

Reactions.—1. *Acetyl chloride* (1 mol.) forms $CH_3.CCl(OZnMe).CH_3$, which is slowly converted, by further treatment with $ZnMe$, into

$CH_3.CMe(OZnMe).CH_3 + ClZnMe$, crystallising in prisms, and converted by water into *tert*-butyl alcohol, CH_3 , zinc chloride, and $Zn(OH)_2$. The compound $CH_3.CCl(OZnMe).CH_3$ yields acetone on addition of water (Butlerow, *Z.* 1864, 365, 702; Pawlow, *N. Petersb. Acad. Bull.* 22, 497; Bogomoletz, *A.* 209, 88).—2. *Bromo-acetyl bromide*, followed by water, yields methyl-isopropyl-carbinol (Winogradoff, *A.* 191, 127).—3. In ethereal solution *secondary hexyl iodide* has no action at 100° ; but at 125° the products appear to be CH_3 , ethyl iodide, and hexylene (Purdie, *C. J.* 39, 464).—4. *Chloral* followed by water forms $CCl_3.CHMe.OH$, while butyric chloral yields $C_4H_7Cl_3.CHMe.OH$.—5. *Nitric oxide* passed into $ZnMe$, forms $CH_3.N_2O_2(ZnMe)$, which is decomposed by water, yielding crystalline $(CH_3.N_2O_2)_2Zn$ aq, from which the Na salt $CH_3.N_2O_2Na$ aq of 'di-nitro-methyl' acid may be obtained (Frankland, *A.* 99, 369).

Zinc ethyl or Zinc ethide $ZnEt$. Mol. w. 123. $[-28^\circ]$ (Haase, *B.* 26, 1053). (118°) . S.G. $\frac{18}{1.182}$. H.F. —31,800 (Guntz, *C. R.* 105, 673). V.D. 4.26 (obs. and calc.).

Formation.—1. By heating zinc or zinc-sodium alloy with EtI or a mixture of EtI and ether (Frankland, *C. J.* 2, 297; 3, 44; *Tr.* 142, 431; 145, 259; *A.* 95, 28; Wanklyn, *C. J.* 13, 124; Pebal, *A.* 118, 22; 121, 105; Rieth a. Beilstein, *A.* 123, 245; 126, 248; Chapman, *Laboratory*, 1, 195; Alexejeff a. Beilstein, *C. R.* 63, 171; Rathke, *A.* 152, 220; Wichelhaus, *J.* 1868, 425).—2. By heating granulated zinc with $HgEt$, in sealed tubes for 36 hours at 100° (Frankland a. Duppa, *C. J.* 17, 8).—3. From zinc filings and $EtBr$ (Wichelhaus, *A.* 152, 321).

Preparation.—Clean zinc filings (180 g.) are mixed with copper (20 g.) reduced from the oxide at a dull-red heat by coal gas; the mixture is rapidly heated over a very large Bunsen flame, and is well shaken meanwhile. As soon as the filings begin to cake together and the copper is no longer visible, the copper-zinc couple has been made. The flask is now connected with an inverted condenser, inclined slightly upwards, and when it is cold ethyl iodide (175 g.) is added. Dry CO_2 is passed through the apparatus, and the flask heated by a water-bath; in half an hour the EtI ceases to run back from the condenser, for it has been converted into $IZnEt$. The apparatus is now tilted so that the condenser is inclined downwards, and heated in a bath of paraffin. The reaction $2IZnEt = ZnI_2 + ZnEt_2$ now takes place, and $ZnEt_2$ (60 g.) is collected in a receiver kept full of CO_2 (Gladstone a. Tribe, *C. J.* 26, 445; 35, 569).

Properties.—Colourless, mobile liquid, fuming in the air, and quickly taking fire, burning with a luminous green-edged flame, and giving off clouds of ZnO . Immediately decomposed by water into $Zn(OH)_2$ and ethane. In like manner it attacks organic compounds containing hydroxyl or amidogen, with elimination of ethane. It causes india-rubber to swell remarkably.

Reactions.—1. Gradually treated with dry oxygen it appears to produce $ZnEt(OEt)$ and $Zn(OEt)_2$, successively (Frankland). According to Demuth a. Meyer (*B.* 23, 394), the passage of oxygen through a solution of $ZnEt$ in ligroin

(7 vols.) yields EtZn.O.O.Et , which is decomposed by heat, sometimes with explosive violence. The compound EtZn.O.OEt sets free I from a solution of KI and yields alcohol when distilled with dilute H_2SO_4 .—2. *Sulphur* forms zinc mercaptide Zn(SEt)_2 . Se appears to act in like manner (Chabrie, *Bl.* [5] 2, 788).—3. *Iodine* forms IZnEt and ZnI_2 successively, together with EtI . Bromine acts in like manner. Zinc ethyl takes fire in chlorine.—4. Dry ammonia forms $\text{Zn(NH}_2)_2$ and ethane (Frankland, *Pr.* 8, 502).—5. *Nitric oxide* is absorbed by an ethereal solution of ZnEt_2 forming crystalline $\text{ZnEt}_2(\text{NO})_2$ which melts below 100° and is split up by water into ethane and $\text{C}_2\text{H}_5\text{N}_2\text{O}_2\text{Zn.OH}$. Carbon dioxide passed into an aqueous solution of this salt ppts. zinc carbonate, while zinc 'dinitroethylate' ($\text{C}_2\text{H}_5\text{N}_2\text{O}_2$) Zn remains in solution (Frankland, *Tr.* 1857, 59; *A.* 99, 342; *C. J.* 37, 570). The salt ($\text{C}_2\text{H}_5\text{N}_2\text{O}_2$) Zn crystallises in prisms, yields NH_3 and NH_4Et on treatment with sodium-amalgam (Zuckschwerdt, *A.* 174, 302), and HNO_3 and NH_4Et on treatment with alcoholic potash (Zorn, *B.* 15, 1008). The dinitroethylates NaA' , BaA' , CaA' , SrA' , MgA' , CuA' , AgA' , and $\text{Ag}_2\text{A'}$ (NO_2) were prepared by Frankland.—6. SO_2 forms zinc ethane sulphinate (Hobson, *C. J.* 10, 455).—7. PCl_5 yields PEt_2 (Hofmann, *A. Cahours*, *Tr.* 1857, 578).—8. SiCl_4 gives SiEt_2 .—9. Heated with EtI at 170° it forms *n*-butane and ZnI_2 . Ethane and ethylene are also formed (Brodie, *C. J.* 3, 405). ZnEt_2 does not act on amyl iodide.—10. Displaces halogens in organic compounds by ethyl.—11. Adds itself to a carbonyl group. Thus with *di-ethyl-ketone* it forms $\text{Et}_2\text{C}(\text{OZnEt})\text{Et}$, which is converted by water into tri-ethyl-carbinol. *Di-propyl ketone* forms, in like manner, ethyl-di-propyl-carbinol. Ketones containing the group CO.CH_3 act differently, forming condensation-products; thus acetone yields mesityl oxide and phorone (A. Saytzeff, *J. pr.* [2] 31, 319). Zinc ethyl has no action on paraldehyde (Wedensky, *J. pr.* [2] 39, 588). With acetic aldehyde it forms $\text{CH}_3\text{CHEt.OZnEt}$, which is converted by water into *sec*-butyl alcohol.—12. In some cases it can add ZnEt and H to a carbonyl group, C_2H_4 being evolved. Thus ZnEt_2 converts *chloral*, dissolved in pure ether, into crystalline $\text{CCl}_3\text{CH}_2\text{OZnEt}$, which is converted by water into tri-chloro-ethyl alcohol (Delacre, *Bl.* [2] 48, 784). Further action of zinc ethide on chloral yields ($\text{CCl}_3\text{CH}_2\text{O}$) Zn , a white powder. In like manner butyric chloral is converted into $\text{C}_2\text{H}_5\text{Cl}_2\text{CH}_2\text{OH}$. In this splitting off of an olefine, ZnEt_2 differs from ZnMe_2 , but resembles zinc propyl and zinc isobutyl (Garzaroli, *A.* 223, 162).—13. Can displace oxygen by two ethyl radicles; thus it converts *oxalic ether* into $\text{CO}_2\text{Et.CEt}_2\text{CO}_2\text{Et}$ (Frankland, *A.* Duppa, *A.* 142, 1; *Pr.* 12, 396).—14. Can displace ethoxyl by ethyl. Thus it converts *formic ether* into $\text{HCEt}(\text{OZnEt})\text{OEt}$ and then into $\text{HCEt}(\text{OZnEt})\text{Et}$, which is turned by water into di-ethyl-carbinol (Wagner, *A.* Saytzeff, *A.* 175, 851).—15. Can displace chlorine by hydrogen. Thus with *chloro-benzoic acid* the first product is probably $\text{C}_6\text{H}_4(\text{ZnEt})\text{CO}_2\text{Et}$, which is converted by water into benzoic ether, C_6H_5 , and ZnO .—16. With *benzonitrile* at 150° , and subsequent treatment with alcohol, cyaphenine is formed (Frankland & Evans, *C. J.* 37, 563). It

polymerises phenyl-acetonitrile in the same way, forming cyanbenzine.—17. *Cyanogen* forms ZnCy_2 and EtCN (Frankland & Graham, *C. J.* 37, 740).—18. *Azobenzene* is reduced by ZnEt_2 , followed by water, to aniline (Frankland & Louis, *C. J.* 37, 563).—19. Acts on primary and secondary amines, giving off ethane, but has no action on tertiary amines (Frankland, *Pr.* 8, 502; Gal, *J. Ph.* [5] 7, 484). ZnEt_2 has no action on nicotine or quinoline, but forms with many alkaloids containing O compounds from which the alkaloids are regenerated by water.—20. *Acetamide* gives $(\text{AcNH})_2\text{Zn}$, while oxamide gives $\text{C}_2\text{O}_2(\text{NH})_2\text{Zn}$.—21. Acts on HgCl_2 forming ClHgEt and HgEt_2 (Buckton, *A.* 109, 218). Hg_2Cl_2 yields HgEt_2 , mercury, and ZnCl_2 .—22. AgCl forms ZnCl_2 , silver, and butane.—23. CCl_4 forms EtCl , ethylene, and propylene (Rieth, *A.* Beilstein, *A.* 124, 242).—24. *Chloroform* yields amylene (R. a. B.), while bromoform gives propylene and EtBr (Alexejeff, *A.* Beilstein, *C. R.* 58, 172). CHCl_3I produces ethylene, butane, and hydrogen (Borodine, *A.* 126, 239).

Zinc bromo-ethide ZnBrEt . [62°]. Formed by the action of the copper-zinc couple on EtBr at 100° (Gladstone & Tribe, *C. J.* 27, 410). Pearly scales, decomposed by heat paray into ZnBr_2 and ZnEt_2 and partly into Zn , ZnBr_2 , C_2H_4 , and C_2H_6 .

Zinc iodo-ethide ZnIEt . Formed in like manner. Crystalline. Split up by heat into ZnI_2 and ZnEt_2 .

Zinc propyl ZnPr_2 . (148°) (S.); (146°) (Gladstone & Tribe, *B.* 6, 1186); (150°) (Pape, *B.* 14, 1873). Formed by heating propyl iodide with zinc and a small quantity of an alloy of zinc and sodium (Stoherbakoff, *Bl.* [2] 87, 345). Heavy liquid, with disagreeable odour. Reacts with aldehydes, forming propylene and such compounds as RCH_2OZnPr , which yield secondary alcohols on addition of water.

Zinc isopropyl ZnPr_2 . (116°) with decomposition; (96° at 40 mm.). Got by heating PrI (170 g.) with ether (100 g.), zinc (100 g.), and zinc-sodium (3 g.) at 100° (Ragozin, *J. R.* 24, 549). Fuming liquid. Yields crystalline Zn(OPr) , on exposure to air. Split up at 182° into Zn and hydrocarbons (Gladstone & Tribe, *C. J.* 39, 6).

Zinc isobutyl $\text{Zn(C}_2\text{H}_5)_2$. (166°) at 784 mm. (Garzaroli-Thurnlackh & Popper, *A.* 223, 167). Formed from zinc and $\text{Pr.CH}_2\text{I}$. Got also from Zn and $\text{Hg(C}_2\text{H}_5)_2$ (Cahours, *Bl.* [2] 21, 357).

Zinc isoamyl $\text{Zn(C}_2\text{H}_5)_2$. (220°). S.G. 2.1022. V.D. 6.95 (calc. 6.87). Prepared by heating zinc with $\text{Hg(C}_2\text{H}_5)_2$ (Frankland, *A.* 85, 860; 130, 122). Liquid, fuming in the air but not taking fire. Takes fire in oxygen. When added to cooled aldehyde it yields, after addition of ice-cold water, methyl-isoamyl-carbinol, iso-propyl-ethylene, and ethyl and isoamyl alcohols (Sokoloff, *C. C.* 1887, 988).

ZINCATES. Compounds derived from ZnO_2H_2 by replacing H by positive , v. ZINC HYDROXIDES, p. 888.

ZIRCONATES v. under ZIRCONIUM HYDROXIDE, p. 896.

ZIRCONIA; oxide of zirconium (q. v., p. 896). **ZIRCONIUM.** *Zr.* At. w. o. 90 (v. p. 894). Mol. w. not known. Melts above m.p. of Si (i.e. above c. 1800°) (Troost, *J.* 1865, 183). S.G. 4.15 (Troost, *loc.*); 4.25 (Moissan, *C. R.* 116,

1222). S.H. (0° – 100°) .066 (Mixer a. Dana, A. 169, 888 [1873]).

Historical.—Klaproth in 1789 (*Beiträge*, 1, 203, 227) announced the discovery of a new earth, in combination with silica, in the rare mineral *zircon*. The same earth has been found in a few other rare minerals, such as *eudialyte*, *polymignite*, *fergusonite*, &c. Bright-coloured varieties of zircon are generally called *hyacinth*, the greyish or brown kinds are called *zirconite*, and a variety which is nearly colourless is known as *jargon*.

In 1845 Svanberg (A. 56, 223) stated that zirconia was a mixture of at least three oxides, but Berlin (*J. pr.* 58, 147), Marignac (A. Ch. [3] 60, 257), and Hermann (*J. pr.* 31, 75; 97, 331) failed to obtain any evidence of the composite character of zirconia. At a later time, Sorby (B. 2, 126, 193 [1869]), and also Forbes (B. 2, 337, 338), thought they had obtained spectroscopic indications of the presence of another earth in *zircon*; but it was shown that the abnormalities observed were due to traces of compounds of uranium (Sorby, C. N. 21, 73; Knop, A. 159, 44; cf. Hannay, C. J. 26, 703).

Occurrence.—Never uncombined. The principal naturally occurring compound of Zr is *zirconite*, which is more or less pure ZrSiO_4 . This mineral is found in small quantities in the sand and alluvial deposits of certain rivers in Ceylon, and in the older rocks in many parts of the world; it has been found in the granites of Sweden, Switzerland, Tyrol, and North America (v. J. M. 1877, 97).

Formation.—1. By heating K_2ZrF_6 with K (Berzelius, P. 4, 117 [1825]).—2. By passing vapour of ZrF_4 over Na in a red-hot tube (Troost, C. R. 61, 109 [1865]).—3. By heating ZrO_2 with Mg (Phipson, *J. pr.* 96, 353 [1865]).—4. By melting ZrO_2 in a carbon crucible in an electric furnace; or by mixing ZrO_2 with carbon, melting in an electric furnace, then mixing the Zr carbides thus formed (v. *Carbides*, p. 894) with excess of ZrO_2 , and again melting (Moissan, C. R. 116, 1222 [1893]).

Preparation.—1. Finely powdered *zirconite* ($\text{ZrO}_2\cdot\text{SiO}_2$) is thoroughly mixed with an excess of finely powdered carbon, the mixture is compressed into small cylinders which are placed in a closed carbon crucible and heated in an electric furnace (with a current of 30 to 35 amperes and 70 volts), while a stream of CO_2 is sent through the crucible; the greater part of the SiO_2 is thus volatilised (Troost, C. R. 116, 1428). The carbides of Zr in the crucible are now mixed with excess of ZrO_2 , and melted in the electric furnace (Moissan, C. R. 116, 1222).—2. Finely powdered and sifted *zirconite* is mixed with 2 to 3 times its weight of KHF_2 , the mixture is heated to bright redness for c. 15 mins., and, after cooling, is boiled with water containing a little dilute HFAg ; K_2SiF_6 is removed by filtration, the filtrate deposits K_2ZrF_6 on cooling. The K_2ZrF_6 is re-crystallised from water, then dried, mixed with K, and heated in a vessel of glass or iron; the product is washed with water, digested for a long time with conc. HClAq at 40° , then washed with water containing NH_4Cl , and finally with alcohol (Berzelius, l.c.; Troost, A. 136, 553). This method yields *amorphous zirconium*. According to Bailey (Pr. 46, 74 [1889]), the only

method that gives nearly pure amorphous Zr is to heat ZrO_2 with Mg foil (not powder) and treat with HClAq .—3. One part dry K_2ZrF_6 is mixed with $1\frac{1}{2}$ pts. Al, and the mixture is heated to the melting-point of iron in a crucible made of gas coke; the product is digested with conc. HClAq diluted with twice its volume of water, when the crystalline leaflets of Zr, that have formed on the surface of the Al, separate from the mass of Al before the latter is wholly dissolved. When the whole of the Al has dissolved an alloy of Zr and Al remains, besides the crystalline leaflets of Zr; if the temperature of reduction is not sufficiently high, the main product is the Zr-Al alloy (Troost, l.c.; cf. Franz, B. 8, 58). This method yields *crystalline zirconium*.

Various methods have been used for decomposing *zirconite* and obtaining compounds of Zr. Franz (B. 8, 58) fuses the powdered mineral with KHSO_4 , treats the fused material with boiling water containing a little H_2SO_4 , washes the insoluble $3\text{ZrO}_2\cdot\text{SO}_3$ thus formed, and adds it, in small portions at a time, to molten NaOH ; he then lixivates with cold water, dissolves the ZrO_2 that remains in hot conc. H_2SO_4 , dilutes, ppts. by NH_4Aq , washes, dries, and decomposes the $\text{ZrO}_2\cdot x\text{H}_2\text{O}$ by heat. The method of fusing with KHF_2 , used by Marignac (v. *supra*, No. 2) yields pure K_2ZrF_6 very readily; $\text{Zr}(\text{SO}_4)_2$ may be obtained by heating the K_2ZrF_6 with conc. H_2SO_4 (v. Hiortdahl, A. 137, 34; cf. J. pr. 83, 201). For other methods v. Hermann (*J. pr.* 97, 330); Soheer (P. 59, 48); Stromeyer (A. 113, 727); Chancel (*J. pr.* 74, 471); Berlin (*J. pr.* 58, 145); Henneberg (*J. pr.* 88, 508); Bailey (Pr. 46, 74 [1889]).

Properties.—Zirconium has been isolated as black amorphous powder, and also as a greyish crystalline solid.

Amorphous zirconium (v. *Preparation*, No. 2) is a black powder, which is extremely porous and resembles powdered charcoal; when pressed with a burnisher it agglomerates to graphite-like laminae. After being heated strongly, and then cooled, *in vacuo*, it is said to glow and burn when exposed to air. The porous amorphous metal is said not to conduct electricity. Amorphous Zr is stated to be insoluble in ordinary acids, including *aqua regia*; but, according to Bailey (Pr. 46, 74 [1889]), it dissolves in cold conc. H_2SO_4 ; HFAg dissolves it readily, H being given off. It is oxidised by heating in the air, when it burns to ZrO_2 with a brilliant white light; oxidation is also effected by fusion with caustic or carbonated alkalis, or with KNO_3 , or KClO_4 .

Crystalline zirconium (v. *Preparation*, No. 3) is a very lustrous, greyish, brittle, solid, which resembles Sb in appearance; very hard, easily scratching glass and ruby (Moissan, C. R. 116, 1222). S.G. 4.15 (Troost, J. 1865, 183); 4.20 (Moissan, l.c.). S.H. (0° to 100°) .066 (Mixer a. Dana, A. 169, 888 [1873]). Crystalline Zr burns in the O-H flame; it is not oxidised in O until heated to whiteness; it dissolves slowly in hot conc. HClAq , and is very slightly acted on by HNO_3Aq or H_2SO_4 , even when warm; cold HFAg dissolves it readily. Molten KClO_4 , or KNO_3 , is said to be without action; molten KOH dissolves the metal as long as any moisture is present.

According to Troost (*J.* 1865. 188), Zr melts above the m.p. of Si (*i.e.* above c. 1800°). The emission-spectrum of Zr has been mapped by Thalén; the chief lines are 6127 in the red, and in the blue, 4815, 4771, 4738, 4709, and 4686.

The at. w. of Zr was determined, (1) by Berzelius (*P.* 4, 126; 8, 186 [1825]), by finding the ratio of ZrO_2 to SO_3 in the sulphate; (2) by Hermann (*J. pr.* 31, 77 [1844]) by analysing $ZrCl_4$; (3) by Marignac (*A. Ch.* [3] 60, 270 [1860]), by analysing K_2ZrF_6 ; (4) by Bailey (*Pr.* 46, 74 [1889]), by decomposing $Zr(SO_4)_2$ by heat and weighing the ZrO_2 produced; (5) by Mixter a. Dana (*A.* 169, 388 [1873]), by determining the S.H. of Zr; (6) by Deville a. Troost (*P.* 108, 636, 641 [1859]), by determining the V.D. of $ZrCl_4$. The results of Berzelius gave the at. w. of Zr as 89.2; those of Hermann, 88.5 to 90.7; those of Marignac, 90.3 to 90.6; and the results obtained by Bailey gave 90.4 as the at. w. of the metal.

Zirconium is the third member of the even-series family of Group IV. in the periodic classification of the elements. This group contains the following elements:—

Even Series	2	4	6	8	10	12
	O	Ti	Zr	Ce	—	Th
Odd Series	3	5	7	9	11	
	Si	Ge	Sn	—	Pb	

As is to be expected from its position in the classificatory system, Zr is a metal with some non-metallic properties; the oxide ZrO_2 forms corresponding salts, many of which are basic salts; the haloid compounds, ZrX_n , are probably all volatilisable without decomposition (the V.D. of $ZrCl_4$ only has been determined), but aqueous solutions yield oxyhalides on evaporation; hydrated ZrO_2 reacts as a weak acid towards strong bases, forming zirconates; salts are known derived from the acid H_2ZrF_6 ; there is an oxide higher than ZrO_2 , probably ZrO_3 . For a more detailed comparison of Zr with the other even-series elements of Group IV. v. TITANIUM GROUP OF ELEMENTS (this vol. p. 749), and cf. TIN GROUP OF ELEMENTS (this vol. p. 735). The atom of Zr is tetravalent in the gaseous molecule $ZrCl_4$.

Reactions and Combinations.—1. Heated in air, or oxygen, Zr burns to ZrO_2 , giving out dazzlingly white light; amorphous Zr burns easily, crystalline only at a white heat, and then merely superficially.—2. Both amorphous and crystalline Zr dissolve readily in *hydrofluoric acid*, giving off H and forming ZrF_4 .—3. According to Bailey (*Pr.* 46, 74), amorphous Zr dissolves in cold conc. *sulphuric acid*. Both forms dissolve in *aqua regia*.—4. Conc. *hydrochloric acid* reacts with Zr, when warm, forming $ZrCl_4$ solution. Crystalline Zr is said to interact with *gaseous hydrogen chloride*, at dull redness, forming $ZrCl_4$.—5. Amorphous Zr is oxidised by *molten potash* or *soda*, also by *molten nitre* or *potassium chlorate*; the crystalline form of Zr is said not to be acted on by molten KNO_3 or $KClO_3$, and by molten caustic alkalis only as long as there are traces of moisture present.—6. Zr combines directly with the *halogens*, to form ZrX_n , and probably with *sulphur* (*v. Sulphide*, p. 897).

Detection and Estimation.—Addition of hot

conc. K_2SO_4 aq. to solutions of salts of Zr pptd. white basic sulphate of Zr, which is insoluble in water and nearly insoluble in much $HClAq$. Turmeric paper becomes reddish-brown when immersed in a solution of a salt of Zr in $HClAq$; the reaction is completely masked by the presence of boric acid (*v. Brush. J. pr.* 62, 7). Bailey (*C. J.* 49, 481 [1886]) found that addition of H_2O_2 aq. to a slightly acid solution containing salts of Zr, along with salts of Fe, Nb, and Ti, pptd. the whole of the Zr as ZrO_3 (or Zr_2O_5), but none of the other metals. Troost makes use of the comparatively small volatility of ZrO_2 at a very high temperature, to separate this oxide from SiO_2 (*v. G. R.* 116, 1428).

Zr is generally estimated as ZrO_2 ; salts of volatilisable acids are decomposed by heat; or solutions may be pptd. by NH_4Aq and the pp. washed, dried, and strongly heated.

Zirconium, alloys of. An alloy of Zr with *aluminium* is obtained in the preparation of Zr by reducing K_2ZrF_6 by Al (*v. Preparation of Zirconium*, No. 3). Mellis (*Z.* [2] 6, 296) obtained crystals having the composition $ZrAl_3$ (or perhaps Zr_2Al_3Si) by heating to whiteness a mixture of 1 pt. powdered *zirconite* with 5 pts. *cryolite* powder, 10 pts. mixed KCl and NaCl, and 1 pt. Al, treating with dilute $HClAq$, and separating the larger crystals of the alloy from the finer crystals of Si.

Zirconium, bromide of, $ZrBr_4$. Formula probably molecular, from analogy of $ZrCl_4$. Obtained by mixing finely powdered ZrO_2 with sugar charcoal, making into balls with starch paste, drying, and heating to bright redness in a current of *dry* CO_2 and *dry* Br (Mellis, *Z.* [2] 6, 296). $ZrBr_4$ is a white, microscopically crystalline, hygroscopic powder; it is easily volatilised; heated in H it is not reduced to a lower bromide. Contact with moist air or water produces the oxybromide $ZrOBr_2$; evaporation of an aqueous solution gives the heptahydrate of this compound $ZnOBr_2 \cdot 7H_2O$ in large needle-shaped, transparent crystals (*M., l.c.*).

Zirconium, carbides of. By heating an intimate mixture of ZrO_2 and C in the electric arc, in an atmosphere of CO_2 , Troost (*C. R.* 116, 1227 [1893]) obtained a very hard, steel-grey solid, approximating closely to the composition ZrC . By using less C, other carbides seem to be produced (*cf. Moissan, C. R.* 116, 1222), but analyses of other compounds are not given. ZrC dissolves easily in dilute $HFAq$, but is not acted on by other acids. Moissan (*l.c.*) says that carbides of Zr containing more than 5 p.c. C (ZrC contains c. 21 p.c. C) take fire fairly easily when exposed to the air; Troost says that carbides with a small proportion of C are only superficially oxidised by heating to redness, but that those with much C burn brilliantly at that temperature.

Zirconium, chloride of, $ZrCl_4$. Mol. w. c. 281.5. V.D. 1.7 at 440° (Deville *ibid.*, *P.* 108, 636).

Formation.—1. By heating Zr in Cl_2 .—2. By heating an intimate mixture of ZrO_2 and C in Cl_2 .—3. By passing vapour of $SiCl_4$ over heated ZrO_2 (Troost a. Hautefeuille, *C. R.* 75, 1819).

Preparation.—A mixture of ZrO_2 with c. its own weight of lampblack is made into a paste with oil; little balls, c. the size of hazel-nuts,

are formed of this, and these are covered with powdered charcoal, and heated to full redness in a closed crucible until the oil is completely charred; the pellets are then heated to bright redness in a tube of hard glass, while a current of dry Cl is passed through the tube; the $ZrCl_4$ which forms on the cooler parts of the tube is sublimed, in a stream of dry Cl, into a tube drawn out into bulbs, which are sealed off when the operation is finished (v. Bailey, *Pr.* 46, 74).

Properties, Reactions, and Combinations.—A white solid; volatilises unchanged at $c. 400^\circ$. Dissolves in water, with production of heat; the solution on evaporation gives *oxychlorides* (*q. v.*). Does not interact with *zinc ethide* at 180° (Hinsberg, *A.* 239, 253). Combines with ammonia to form $ZrCl_4 \cdot 4NH_3$; with *sodium chloride* to form $ZrCl_4 \cdot 2NaCl$ (Paykull, *B.* 6, 1467).

Zirconium, ferrocyanide of. According to Hornberger (*A.* 181, 232), the pp. formed by adding K_4FeCy_6 aq. to a solution of a salt of Zr, when washed and dried, has the composition $Zr_3(FeCy_6)_2$ (?); it is a blue powder with a greenish tinge, insoluble in water, decomposed by acids, giving off HCN.

Zirconium, fluoride of, ZrF_4 . Formula probably molecular, from analogy of $ZrCl_4$.

Formation.—1. The *hydrated* compound $ZrF_4 \cdot 8aq$ is formed by slowly evaporating a solution of $ZrO_2 \cdot H_2O$ or ZrF_4 in $HFAq$.—2. By heating ZrO_2 with twice its weight of $(NH_4)HF_2$ to dull redness, till all the ammonium salt is volatilised (Marignac, *A. Ch.* [3] 60, 263).

Preparation.—Deville (*A. Ch.* [3] 49, 84) obtained ZrF_4 by heating to whiteness a mixture of finely powdered *zirconite* and *fluorspar* in a stream of HCl (? $ZrSiO_4 + 2CaF_2 + 2HCl = ZrF_4 + CaCl_2 + CaSiO_3 + H_2O$).

Properties and Reactions.—Prepared as described, ZrF_4 is a colourless, transparent, crystalline (probably hexagonal) solid; volatilisable at white heat; insoluble in water and acids. ZrF_4 prepared by heating ZrO_2 with $(NH_4)HF_2$ is said to be soluble in water and in dilute $HFAq$. The crystals of $ZrF_4 \cdot 8aq$ are partially decomposed on drying. Heated to full redness in air, ZrF_4 gives ZrO_2 and HF.

Combinations.—1. With water (v. *Formation*, No. 1) to form $ZrF_4 \cdot 8aq$.—2. With various *metallic fluorides* to form compounds of the form $ZrF_4 \cdot xMF_y \cdot yH_2O$. These salts are often called *zircono-fluorides*, or *fluoro-zirconates*; they are better named *zirconio-fluorides*. The zirconio-fluorides have been examined chiefly by Marignac (*A. Ch.* [3] 60, 257); they are obtained either by gradual evaporation of solutions containing the constituent fluorides, or by adding hydroxides or carbonates of the various metals to solutions of ZrF_4 in $HFAq$, and evaporating.

Ammonium zirconio-fluorides. Two salts are described: (1) $2NH_4F \cdot ZrF_4 = (NH_4)_2ZrF_6$, rhombic crystals, isomorphous with K_2ZrF_6 ; (2) $3NH_4F \cdot ZrF_4$, small octahedra, showing simple refraction (Baker, *C. J.* 35, 762).

Cadmium zirconio-fluorides. Two salts seem to exist: (1) $2CdF_2 \cdot ZrF_4 \cdot 6aq$, monoclinic crystals, isomorphous with the Mn salts; (2) $CdF_2 \cdot 2ZrF_4 \cdot Caq$, laminar, fan-shaped groups of crystals.

Manganese zirconio-fluorides. (1) $MnF_2 \cdot ZrF_4 \cdot 5aq$; and (2) $2MnF_2 \cdot ZrF_4 \cdot 6aq$.

Nickel zirconio-fluorides.

(1) $NiF_2 \cdot ZrF_4 \cdot 6aq$, hexagonal prisms; S.G. 2.227 (Topsøe, *C. C.* 4, 76); and (2) $2NiF_2 \cdot ZrF_4 \cdot 12aq$, monoclinic crystals. The first salt forms a *double salt* with K_2ZrF_6 , viz. $NiZrF_6 \cdot K_2ZrF_6 \cdot 8aq$.

Potassium zirconio-fluorides.

(1) K_2ZrF_6 ; obtained by strongly heating *zirconite* with two or three times its weight of KHF_2 , boiling with very dilute $HFAq$, filtering from K_2SiF_6 , and allowing the filtrate to cool. Crystallises in rhombic crystals, terminated by six-sided pyramids; solubility = .78 at 2° , 1.4 at 15° , 1.7 at 19° , and 25 at 100° . S.G. 3.582 (Topsøe, *l.c.*); (2) $KF \cdot ZrF_4 \cdot aq (= KZrF_5 \cdot aq)$; obtained, in monoclinic crystals, by dissolving the preceding salt in water containing a large excess of ZrF_4 . (3) $3KF \cdot ZrF_4 (= K_3ZrF_7)$; obtained by crystallising K_2ZrF_6 from a solution containing excess of KF; small, brilliant, regular octahedra, with simple refraction (v. Baker, *C. J.* 35, 762). Soluble in water; the hot conc. solution deposits K_2ZrF_6 on cooling.

Sodium zirconio-fluorides. The salt $5NaF \cdot 2ZrF_4$ is said to be always formed in whatever proportion the constituent fluorides are mixed. Small, monoclinic crystals; solubility at $18^\circ = .38$, and at $100^\circ = c. 1.6$.

Zinc zirconio-fluorides. (1) $ZnZrF_6 \cdot 6aq$; isomorphous with $ZnSiF_6 \cdot 6aq$ and $ZnSnF_6 \cdot 6aq$, crystallising in regular hexagonal prisms, easily soluble in water. S.G. 2.255 (Topsøe, *l.c.*). (2) $2ZnF_2 \cdot ZrF_4 \cdot 12aq$; deposited from a solution containing excess of ZnF_2 in monoclinic crystals, isomorphous with $2NiF_2 \cdot ZrF_4 \cdot 12aq$.

Zirconium, hydride of. By heating ZrO_2 and Mg powder, in the ratio $ZrO_2 : 2Mg$, in an atmosphere of H, Winkler (*B.* 24, 888; *cf. B.* 23, 2666) obtained a black powder which burnt in O, and contained c. .73 p.c. H. On treating this with dilute $HClAq$, Mg and MgO dissolved, H being given off, and a black residue was left which W. regarded as ZrH_2 . Supposing the reduction of the ZrO_2 had proceeded in accordance with the equation $ZrO_2 + 2Mg + 2H = 2MgO + 2ZrH_2$, the product would have contained 53.44 p.c. ZrH_2 , and, therefore, would have given 1.15 p.c. H; as only .73 p.c. H was found, W. concluded that c. $\frac{1}{3}$ of the ZrO_2 had been reduced.

Zirconium, hydroxide of, (?) $ZrO_2 \cdot H_2O$. Addition of NH_4Aq to a solution of a salt of Zr produces a white, bulky, gelatinous pp. of $ZrO_2 \cdot xH_2O$. According to Berzelius, the dry pp. has the composition $ZrO_2 \cdot H_2O = ZrO_2 \cdot H_2$; Hermann (*J. pr.* 97, 318) gave the formula $ZrO_2 \cdot 2H_2O = ZrO_2 \cdot H_4$, to the pp. dried at 17.5° ; Paykull (*B.* 12, 1719) said that after drying *in vacuo* the composition was $ZrO_2 \cdot 3H_2O$, and after drying at 100° $ZrO_2 \cdot H_2O$. A detailed examination of the dehydration of the pp. formed by adding NH_4Aq to a cold solution of $Zr(SO_4)_2$, was made by Carnelley & Walker (*C. J.* 53, 68, 82 [1888]). The loss of water by the air-dried pp. was fairly regular to c. 90° , when the pp. had approximately the composition $ZrO_2 \cdot 2H_2O$; the loss was then less rapid, but very regular, up to c. 385° , whereat the composition was approximately $2ZrO_2 \cdot H_2O$; somewhere between 385° and 415° there was a sudden increase in the percentage loss of water

for a rise of 10° , this increase being accompanied by a change of colour from grey to pure white; at 415° the composition was approximately $24\text{ZrO}_2 \cdot \text{H}_2\text{O}$; water was then given off very regularly, until at c. 550° dehydration was completed. C. a. W. conclude that probably no definite hydrate of ZrO_2 , unchanged throughout a fair range of temperature, is formed by heating $\text{ZrO}_2 \cdot x\text{H}_2\text{O}$ ppd. from a salt of Zr; they think that the change of colour which accompanies the comparatively large percentage loss of water at c. 400° is an accompaniment of a condensation of molecules chiefly of the composition $n(2\text{ZrO}_2 \cdot \text{H}_2\text{O})$ to molecules chiefly of the composition $n(24\text{ZrO}_2 \cdot \text{H}_2\text{O})$. There is a distinct resemblance between the phenomena of the dehydration of $\text{ZrO}_2 \cdot x\text{H}_2\text{O}$ and those of the dehydration of $\text{SiO}_2 \cdot x\text{H}_2\text{O}$, $\text{SnO}_2 \cdot x\text{H}_2\text{O}$, and $\text{TiO}_2 \cdot x\text{H}_2\text{O}$.

Hydrated ZrO_2 ppd. cold, and washed with cold water, dissolves easily in the ordinary acids, including oxalic acid (Bailey, *C. J.* 49, 481), forming salts ZrX^{I} , and ZrX^{II} ; when ppd. hot, or washed with hot water, the pp. is only slowly dissolved by the ordinary acids. According to Paykull (*B.* 12, 1719), moist $\text{ZrO}_2 \cdot x\text{H}_2\text{O}$ absorbs CO_2 from the air. Digestion with $\text{Zr}(\text{SO}_4)_2\text{Aq}$ produces basic sulphates $3\text{ZrO}_2 \cdot 4\text{SO}_3$, 15aq and $6\text{ZrO}_2 \cdot 7\text{SO}_3$, 19aq (P., l.c.).

Zirconates. $\text{ZrO}_2 \cdot x\text{H}_2\text{O}$ behaves as a weak acid towards the stronger bases. A few salts have been prepared which are most simply regarded as derived from $\text{Zr}(\text{OH})_2$ by replacing H by alkali and alkaline earth metals; these zirconates are obtained by heating ZrO_2 with bases; they have been examined chiefly by Hiortdahl (*A.* 187, 34, 236 [1865]).

Sodium zirconates. (1) Na_2ZrO_3 ($=\text{Na}_2\text{O} \cdot \text{ZrO}_2$); obtained by heating ZrO_2 with Na_2CO_3 in the ratio $\text{ZrO}_2:\text{Na}_2\text{CO}_3$; the crystalline mass thus formed is gradually decomposed by water with separation of amorphous ZrO_2 . (2) Na_4ZrO_5 ($=2\text{Na}_2\text{O} \cdot \text{ZrO}_2$); obtained by heating ZrO_2 with a considerable excess of Na_2CO_3 to whiteness for a considerable time; decomposed by water, with formation of (3) $\text{Na}_2\text{O} \cdot 0.8\text{ZrO}_2$, 12aq, which forms hexagonal tablets.

Zirconates of calcium and magnesium were obtained by H (l.c.) by heating to redness mixtures of ZrO_2 with SiO_2 and CaCl_2 or MgCl_2 . Ouvrard (*C. R.* 112, 1444 [1891]) describes *lithium zirconate*, Li_2ZrO_3 , obtained by fusing ZrO_2 with LiCl , and cooling slowly; when Li_2CO_3 was used, and the fused mass was treated with boiling water containing a little acetic acid, pure ZrO_2 remained.

Zirconium, nitride of. In fusing amorphous Zr with Al, in a cracked lime crucible, Mallet (*Am. S.* [2] 28, 346 [1858]) obtained a dark-grey, porous solid, which gave yellowish lustrous microscopic cubes when treated with HClAq ; the crystals were unchanged by *aqua regia* or alkali solutions; when fused with KOH they gave off NH_3 . The yellow crystals were probably a nitride of Zr.

Zirconium, oxides of. Besides zirconia, ZrO_2 , there exists a higher oxide, probably ZrO_3 ; and, possibly, also a lower oxide (?) ZrO .

Zirconium dioxide ZrO_2 . (*Zirconia. Zirconic anhydride.*) Mol. w. not known.

Preparation.—There are many methods for

preparing ZrO_2 from *zirconite*. 1. The mineral is heated to redness and thrown into water, and the least-coloured pieces are finely powdered and levigated; the powder is very strongly heated with four times its weight of Na_2CO_3 , in a Pt crucible, and the product is heated with excess of HClAq ; the whole is evaporated to dryness; the residue is digested with water, filtered from SiO_2 , and $\text{ZrO}_2 \cdot x\text{H}_2\text{O}$ is ppd. by NH_3Aq . The pp. is washed and dissolved in HClAq , and the solution is nearly saturated with Na_2CO_3 , and boiled with $\text{Na}_2\text{S}_2\text{O}_3\text{Aq}$ as long as SO_2 is given off, whereby $\text{ZrO}_2 \cdot x\text{H}_2\text{O}$ is ppd. (Berzelius, *P.* 4, 124; 8, 186; Hermann, *J. pr.* 31, 77; Chancel, *A.* 108, 287; Stromeyer, *A.* 113, 127).—2. Very finely powdered *zirconite* is boiled with conc. HClAq , and the residue is washed with water and dried; 100 g. of the dried powder are added to 400 g. molten NaOH , with which 20 g. NaF have been mixed, and the whole is heated in a nickel crucible until the action ceases, when the molten mass is poured on to a sheet of nickel, and, after solidification, is plunged into water; the portion insoluble in water is dissolved in HClAq , the solution is evaporated to dryness, and treatment with HClAq and evaporation to dryness are repeated several times to remove SiO_2 and HF . The solution in HClAq is then ppd. by NH_3Aq ; the $\text{ZrO}_2 \cdot x\text{H}_2\text{O}$ is thoroughly washed by decantation, dissolved in the smallest possible quantity of conc. HClAq , and the solution is evaporated to dryness; the residue is washed in a funnel with conc. HClAq mixed with 4 pts. of alcohol; the washed solid is then repeatedly crystallised from conc. HClAq . The white, lustrous crystals of $\text{ZrOCl}_2 \cdot x\text{H}_2\text{O}$ thus obtained are dissolved in water, and $\text{ZrO}_2 \cdot x\text{H}_2\text{O}$ is ppd. by NH_3Aq (Venable, *C. N.* 64, 315 [1891]; cf. Bailey, *Pr.* 46, 74 [1889]; cf. *Preparation of Zirconium*, p. 893). By heating ppd. $\text{ZrO}_2 \cdot x\text{H}_2\text{O}$ to c. 550° , ZrO_2 is obtained.

Crystalline zirconia is obtained from the amorphous form (1) by fusing with borax at a very high temperature, and washing with HClAq (Nordenskjöld, *P.* 114, 612; Knop, *A.* 157, 368); (2) by fusion with *microcosmic salt* (K., l.c.); (3) by heating to dull redness in dry HCl at a pressure of three atmospheres (Hautefeuille a. Perrey, *C. R.* 110, 1038); (4) by melting and volatilising in an electric furnace, using a current of 860 amperes and 70 volts (Moissan, *C. R.* 116, 1222 [1893]); (5) by heating, to dull redness, a salt of Zr with an acid that can be removed by heating, in a current of dry HCl (H. a. P., l.c.).

Properties.—Amorphous zirconia is a white, tasteless, inodorous powder; S.G. c. 5; insoluble in acids, except in conc. H_2SO_4 (*v. Reactions*, No. 7) or HFAq . Crystalline zirconia is a transparent, colourless solid; S.G. 5.1 (Moissan, l.c.), 5.42 (Knop, l.c.), 5.7 (Nordenskjöld, l.c.). The crystals are described by N. (l.c.) as quadratic prisms, isomorphous with SnO_2 (*tinstone*) and TiO_2 (*rutile*). The crystals are extremely hard; they scratch glass easily (Moissan, l.c.). It is generally said that when ZrO_2 is heated to incipient redness it glows brightly, and becomes denser; but the experiments of Carnelley a. Walker (*J. S.* 58, 82 [1888]) on the action of heat on $\text{ZrO}_2 \cdot x\text{H}_2\text{O}$

make it probable that the glowing is an accompaniment of the dehydration from approximately $2\text{ZrO}_2 \cdot \text{H}_2\text{O}$ to approximately $24\text{ZrO}_2 \cdot \text{H}_2\text{O}$. Zirconia reacts towards acids as a basic oxide, forming salts ZrX_2 and ZrX_3 , (many of which are basic salts); it also decomposes alkali carbonates, and some other alkali and alkaline earth-salts, when fused therewith, forming zirconates $m\text{ZrO}_2 \cdot n\text{M}_2\text{O}$ (v. *Zirconates*, p. 896).

Reactions.—1. When ZrO_2 is heated to a very high temperature it melts, boils, and volatilises, condensing in crystals; Moissan (*C. R.* 116, 1222 [1893]) effected the volatilisation in a crucible heated in the electric furnace, using a current of 860 amperes and 70 volts.—2. When very strongly heated with excess of carbon, carbides are formed (v. *Carbides*, p. 894). Heating in a carbon crucible in the electric furnace produces Zr (M., l.c.).—3. Heating with magnesium produces Zr, perhaps also an oxide lower than ZrO_2 (Winkler, *B.* 23, 2642; 24, 888; Phipson, *J. pr.* 96, 35f; Bailey, *Pr.* 46, 74; cf. *Zirconium monoxide*). When heated with magnesium in an atmosphere of hydrogen, some ZrH_2 is perhaps produced (v. *Zirconium hydride*, p. 895).—4. ZrCl_4 is formed by heating ZrO_2 mixed with carbon in a stream of chlorine; using bromine produces ZrBr_4 (v. *Bromide and Chloride*, p. 894).—5. ZrF_4 is formed by heating ZrO_2 to dull redness with excess of ammonium fluoride.—6. K_2ZrF_6 is formed by slightly heating ZrO_2 with excess of potassium hydrogen fluoride, boiling with very dilute HFAg , and filtering.—7. $\text{Zr}(\text{SO}_4)_2$ is obtained by heating ZrO_2 with excess of a mixture of 2 pts. conc. sulphuric acid and 1 pt. water.

ZIRCONIUM PEROXIDE. By adding $\text{H}_2\text{O}_2\text{Aq}$ and NH_4Aq to a solution of $\text{Zr}(\text{SO}_4)_2$, Clève (*Bt.* [2] 43, 53) obtained an oxide containing more O than ZrO_2 ; to this oxide he gave the formula ZrO_3 . Bailey in 1886 (*C. J.* 49, 149, 481) examined the pp. obtained by adding $\text{H}_2\text{O}_2\text{Aq}$ to solution of $\text{Zr}(\text{SO}_4)_2$; according to B., the moist pp. has the composition Zr_2O_5 , and this composition is unchanged after keeping (moist) for some months. In Bailey's paper in 1889 (*Pr.* 46, 74) he gives the composition $\text{ZrO}_2 \cdot 3\text{H}_2\text{O}$ to the oxide ppd. by $\text{H}_2\text{O}_2\text{Aq}$, either from an acid or an alkaline solution of $\text{Zr}(\text{SO}_4)_2$, after drying over P_2O_5 ; and the composition Zr_2O_5 after drying at 100° . The oxide $\text{ZrO}_2 \cdot x\text{H}_2\text{O}$ was obtained (*C. J.* 49, 485) by preparing a solution of $\text{Zr}(\text{SO}_4)_2$ by heating K_2ZrF_6 with H_2SO_4 , and at once adding $\text{H}_2\text{O}_2\text{Aq}$. Zr peroxide is insol. in very dilute (1 p.c.) $\text{H}_2\text{SO}_4\text{Aq}$ or $\text{H}_2\text{O}_2\text{H}_2\text{O}_2\text{Aq}$ (B., l.c.). Bailey (l.c.) employed the ppn. of $\text{ZrO}_2 \cdot x\text{H}_2\text{O}$ to separate Zr from Fe, Nb, and Ti.

ZIRCONIUM MONOXIDE (?) ZrO . By heating ZrO_2 and powdered Mg, in the ratio $\text{ZrO}_2 \cdot \text{Mg}$, in a stream of H, Winkler (*B.* 23, 2668 [1890]) obtained a black powder, which he allowed to cool in H, then kept for some time in CO_2 , freed from Mg by treatment with dilute HClAq , washed with water containing HCl , then with alcohol, and finally with ether, and dried *in vacuo*. He thus obtained a deep-black powder, which was unacted on by HClAq , HNO_3Aq , or $\text{H}_2\text{SO}_4\text{Aq}$, even on warming, and which burnt to ZrO_2 when heated in air. W. supposed this black powder to be ZrO .

VOL. IV.

Zirconium, oxyacid of. Hydrated zirconia, $\text{ZrO}_2 \cdot x\text{H}_2\text{O}$, reacts as a weak acid towards strong bases (v. *ZIRCONATES*, p. 896).

Zirconium, oxybromide of, $\text{ZrOBr}_2 \cdot x\text{H}_2\text{O}$. ZrBr_4 dissolves in water; on evaporation, transparent needle-shaped crystals are formed, to which Mellis (*Z.* [2] 6, 296) gave the composition $\text{ZrOBr}_2 \cdot 7\text{H}_2\text{O}$. By dissolving $\text{ZrO}_2 \cdot x\text{H}_2\text{O}$ in HBrAq and evaporating, Weibull (*B.* 20, 1894 [1887]) obtained lustrous needles of $\text{ZrOBr}_2 \cdot 8\text{H}_2\text{O}$, isomorphous with $\text{ZrOCl}_2 \cdot 8\text{H}_2\text{O}$.

Zirconium, oxychlorides of. Various oxychlorides have been described. (1) $\text{ZrOCl}_2 \cdot x\text{H}_2\text{O}$; prepared by dissolving $\text{ZrO}_2 \cdot x\text{H}_2\text{O}$ in HClAq and evaporating (for details as to the best conditions v. Weibull, *B.* 20, 1394). Hermann (*J. pr.* 81, 77) gave the formula as $\text{ZrOCl}_2 \cdot 9\text{H}_2\text{O}$; Mellis (*Z.* [2] 6, 296) gave $2\text{ZrOCl}_2 \cdot 9\text{H}_2\text{O}$; and Weibull (l.c.) $\text{ZrOCl}_2 \cdot 8\text{H}_2\text{O}$ (v. also Paykull, *B.* 6, 1467; and Bailey, *Pr.* 46, 74). (2) Zr_2OCl_4 ; prepared by Troost a. Hautefeuille (*C. R.* 73, 563) by passing steam and vapour of ZrCl_4 through a red-hot tube. (3) $2\text{Zr}_2\text{O}_7\text{Cl}_4 \cdot 15\text{H}_2\text{O}$; prepared by Endemann (*J. pr.* [2] 11, 219) by adding ether to a warm alcoholic solution of $\text{ZrOCl}_2 \cdot x\text{H}_2\text{O}$.

Zirconium, oxydides of. By adding the calculated weight of BaI_2 in solution, to $\text{Zr}(\text{SO}_4)_2$ dissolved in a slight excess of $\text{H}_2\text{SO}_4\text{Aq}$, filtering, evaporating over H_2SO_4 , and removing free I from the residue by CS_2 , Hinsberg (*A.* 239, 253 [1887]) obtained a white, amorphous powder, easily soluble in water, giving off I in moist air, to which he gave the formula $\text{ZrIO}_2 \cdot x\text{H}_2\text{O}$ (x probably = 3).

Zirconium, oxysulphide of; v. ZIRCONIUM SULPHIDES (infra).

Zirconium, salts of. The salts formed by the replacement of H of acids by Zr belong to the forms ZrX_2 and ZrX_3 ; many basic salts are known. The following are the chief salts of Zr derived from oxyacids:—*Arsenates, borates, carbonates, nitrates, oxalates, phosphates, selenites, silicates, sulphates, and sulphites.*

Zirconium, silicofluoride of, (?) ZrSiF_6 ; probably obtained by Berzelius by evaporating a solution (? of $\text{ZrO}_2 \cdot x\text{H}_2\text{O}$ in $\text{H}_2\text{SiF}_6\text{Aq}$) (v. *Lehrbuch*, 3, 505 [5th ed.]).

Zirconium, sulphides of. According to Berzelius (v. *Lehrbuch*, 2, 189 [5th ed.]), a compound of Zr and S is formed by heating the elements together *in vacuo*, or with H. The compound, to which no formula is assigned, is described by B. as a dark-brown coloured powder; unacted on by $\text{H}_2\text{SO}_4\text{Aq}$, HNO_3Aq , or HClAq ; slowly attacked by boiling *aqua regia*; dissolved easily by HFAg , giving off H_2S ; insol. in KOH and ZrO_2 . By strongly heating ZrO_2 in vapour of CS_2 , Frey (*A. Ch.* [3] 83, 326 [1853]) obtained a graphite-like solid, which was rapidly acted on by HNO_3Aq , with separation of S; Frey supposed that the substance might be an oxy-sulphide.

Zirconium, sulphocyanide of. By adding $\text{Ba}(\text{SCN})_2$ to $\text{Zr}(\text{SO}_4)_2$ solution, Hornberger (*A.* 181, 232 [1876]) obtained a solution which, he said, contained $\text{Zr}(\text{SCN})_2$; this solution quickly decomposed, depositing a yellow solid, while $\text{Zr}(\text{SCN})_2$ remained in solution.

ADDENDA.

[DESCRIPTIVE INORGANIC CHEMISTRY ONLY.]

ALUMINIUM (vol. i. p. 141). *Preparation.*—

By electrolysis of a molten mixture of $\text{AlF}_3 \cdot 3\text{NaF}$ with NaCl (Minet, *C. R.* 111, 603 [1890]). The best results are obtained by using the salts in the ratio $\text{AlF}_3 \cdot 3\text{NaF} : 6\text{NaCl}$; details of the quantities to be used, the strength of current, &c., are given by M.

Properties.—Minet (*C. R.* 111, 603 [1890]) gives m.p. of Al as 675° ; and S.G. at 820° as 1.76. The S.H. of Al is given by Richards (*C. N.* 65, 97 [1892]) as 224 at 20° , 232 at 100° , and 2845 at the m.p. = 625° ; the S.H. of molten Al at $650^\circ = 308$, according to Pionchon (*C. R.* 115, 162 [1892]). The molecule of Al in dilute solution in tin is perhaps diatomic (Heycock & Neville, *C. J.* 57, 876 [1890]).

Reactions.—Volatilises in electric furnace, with current of 250 ampères and 70 volts (Moissan, *C. R.* 116, 1429 [1893]). Not appreciably acted on by NO_2 at 500° (Sabatier & Senderens, *C. R.* 116, 236 [1892]). An amalgam is formed by bringing Al into a solution of a mercuric salt (Klaudy, *C. C.* 1893 [1] 201; abstract in *C. J.* 64 [11] 376 [1893]). Heated with NaPO_3 in a current of H, from 28 to 31 p.c. of the P distils over; P is also obtained by heating Al with any phosphate of Ca or Mg (Rossel a. Frank, *B.* 27, 52 [1894]). According to Lunge (*C. N.* 65, 110 [1892]), vessels made of Al may be used for holding articles of food, at least at the ordinary temperature, without danger of the metal being dissolved; this result is confirmed by Balland (*C. R.* 114, 1536 [1892]).

Aluminium, alloys of (vol. i. p. 148). For an alloy with gold, Al_2Au , v. Heycock & Neville (*C. J.* 65, 74 [1894]).

Aluminium, chloride of (vol. i. p. 144). Nilson a. Pettersson (*Z. P. C.* 4, 206 [1889]) made a number of determinations of the V.D. of AlCl_3 ; they find that the compound gradually dissociates above its b.p. until c. 800° , when its V.D. becomes constant and corresponds with the formula AlCl_3 . AlCl_3 may be prepared by heating an alloy of Al and Cu nearly to redness in dry HCl; AlCl_3 distils over unmixed with any Cu compound (Mabery, *B.* 22, 2658 [1889]). Sabatier (*B.* [3] 1, 88 [1889]) says that crystals of the hydrated chloride after being *in vacuo* for three months at 20° over H_2SO_4 have the composition $\text{AlCl}_3 \cdot 6\text{H}_2\text{O}$.

Aluminium, oxides of (vol. i. p. 146). By heating Al_2O_3 with Mg, in the ratio $\text{Al}_2\text{O}_3 : \text{Mg}$, Winkler (*B.* 23, 780 [1890]) obtained a brownish-black powder which, he says, contained a considerable quantity of an oxide lower than Al_2O_3 , probably AlO . By the incomplete combustion of Al, Pionchon obtained a dark-grey powder, said by P. to have the composition $\text{Al}_2\text{O}_3 \cdot 2\text{Al}_2\text{O}_3 \cdot \text{Al}_2\text{O}_3$ (*C. R.* 117, 828; abstract in *C. J.* 64 [11] 572 [1893]). By heating amorphous Al_2O_3 to in-

ipient redness in HCl gas at a pressure of three atmos., Hautefeuille a. Perrey (*C. R.* 110, 1038 [1890]) obtained crystals of *corundum*. According to Read (*C. J.* 65, 818 [1894]), Al_2O_3 is unchanged at c. 1750° .

Aluminium, phosphide of (vol. i. p. 146). A grey crystalline powder, Al_2P_3 , was obtained by Rossel a. Frank (*B.* 27, 52 [1894]) by heating Al in vapour of P, and then heating the product till P ceased to come off.

AMMONIA (vol. i. p. 196). *Formation.*—According to Loew (*B.* 23, 1443 [1890]), traces of NH_3 are formed by shaking Pt black with very dilute NaOHAq in the air. NH_3 is also formed by the combined action of Pt black and dextrose on KNO_3Aq (L., *l.c.*, p. 675).

Properties.—Ludeking a. Starr (*Am. S.* [3] 45, 200 [1892]) give S.H. of liquid NH_3 as 8857 . For measurements of the wave-lengths of the lines in the emission spectrum of NH_3 , v. Magnanini (*Z. P. C.* 4, 435 [1889]). Perkin (*C. J.* 55, 689, 728 [1889]) gives M. M. of NH_3 in aqueous and alcoholic solutions; also Mol. R. of various NH_3 salts in solution. Tables showing the solubility of NH_3 in alcohol of various concentrations, at 10° , 20° , and 30° , are given by Delépine (*J. Ph.* [5] 25, 496; v. abstract in *C. J.* 62, 1049 [1892]). For the freezing-points of aqueous solutions of NH_3 , v. Pickering (*C. J.* 63, 181 [1893]).

Reactions.—Dry NH_3 does not combine with dry hydrogen chloride when these gases are mixed (Baker, *C. J.* 65, 611 [1894]). Nor do dry NH_3 and dry carbon dioxide combine (Hughes a. Soddy, *C. N.* 69, 138 [1894]). Michel a. Grandmoulin (*B.* 26, 2565 [1893]) say that the products of passing NH_3 over heated peroxide of Ba, Pb, Mn, or Na, are N with a little HNO_2 and HNO_3 , and oxide or hydroxide of the metal. The reactions of liquid NH_3 with CrCl_3 and FeCl_3 are described by Christensen (*Zeit. f. anorg. Chem.*, 4, 227; abstract in *C. J.* 64 [11] 469 [1893]).

AMMONIUM COMPOUNDS (vol. i. p. 200).

Ammonium amalgam (vol. i. p. 201). From measurements of the polarisation given by this substance in a solution of NH_4Cl against zinc amalgam, and a comparison of these measurements with the polarisations given by metallic amalgams, Le Blanc concludes that ammonium amalgam really exists (*Z. P. C.* 5, 467; abstract in *C. J.* 58, 1204 [1890]).

Ammonium chloride (vol. i. p. 202). Baker (*C. J.* 65, 611 [1894]) asserts that the V.D. of the dry salt at 850° is 28.7, corresponding with that required by the formula NH_4Cl . B. also says that no reaction occurs when dry NH_4Cl and dry CaO are heated together.

ANTIMONY (vol. i. p. 282). *Reactions.*—Montemartini (*G.* 22, 864, 426) finds that no

appreciable quantity of NH_3 is formed by the interaction of Sb and HNO_3 varying from 2 to 70.8 p.c. HNO_3 ; NO_2 is practically the only gaseous product of the reaction; when 70 p.c. HNO_3 is used, the residue probably has the composition $(\text{SbO})\text{NO}_2$.

Antimonates (vol. i. p. 285). Several salts have been prepared, by double decomposition from the K salt, by Peilstein and O. v. Bläse (*C. C.* 1889. 803; *abstract in C. J.* 56, 1123). All the compounds are salts of HSbO_3 ; B. a. B. concludes that the only well-marked antimonates are derived from this acid. Ebel (*B.* 22, 3044 [1889]) describes several metantimonates.

Antimonites (vol. i. p. 285). For antimonites of K and Na v. Gormimbœuf (*C. R.* 115, 1805; *abstract in C. J.* 64 [11], 171 [1893]).

Antimony, bromide of (vol. i. p. 286). The b.p. of SbBr_3 is given as 275° by Freyer a. V. Meyer (*Zeit. f. anorg. Chemie*, 2, 1 [1892]).

Antimony, trichloride of (vol. i. p. 286). Boils at 228° (Freyer a. V. Meyer, *l.c.*).

Antimony, pentachloride of (vol. i. p. 287). The V.D. at 218° and 58 mm. pressure was found to be 144.7 (corresponding with the formula SbCl_5) by Anschütz a. Evans (*A.* 25, 95 [1890]). Double compounds of SbCl_5 with RbCl and CsCl are described by Saunders (*Am.* 14, 152 [1892]), and by Wheeler (*Am. S.* [3] 46, 269 [1893]).

Antimony, fluoride of (vol. i. p. 287). The double compound $\text{SbF}_2 \cdot 2\text{AMF}$ is described by H. von Helmholtz (*Zeit. f. anorg. Chemie*, 3, 115 [1893]).

Antimony, hydride of (vol. i. p. 288). The temperature whereat decomposition of SbH_3 begins is given by Brunn (*B.* 22, 3202 [1889]) as c. 150° . For the reactions of SbH_3 with AgNO_3 v. Vitali (*abstract in C. J.* 64 [11], 206 [1893]).

Antimonic oxide (vol. i. p. 290). When heated to dull redness Sb_2O_5 gives off O, forming Sb_2O_3 , which at $c. 1750^\circ$ is further reduced to Sb_2O_3 (Read, *C. J.* 65, 313 [1894]).

Antimonious sulphide (vol. i. p. 291). Black Sb_2S_3 is formed, according to Mitchell (*C. N.* 67, 291 [1893]), by passing CO_2 into boiling water with ordinary Sb_2S_3 in suspension. Picton (*C. J.* 61, 142 [1892]) obtained a colloidal Sb_2S_3 in very fine suspension in water, by allowing solution of tartar emetic to flow into saturated H_2SAq .

Antimony, thio-chlorides and thio-iodides of (vol. i. pp. 292-3). Ouvrard (*C. R.* 116, 1516 [1893]) describes SbSCl and $\text{Sb}_2\text{S}_2\text{Cl}_2$, obtained by the action of H_2S on SbCl_3 ; and SbSI formed by heating SbI_3 to 150° in dry H_2S , and $\text{Sb}_2\text{S}_2\text{I}_2$ formed by heating Sb_2S_3 with I and crystallising from CS_2 .

ARSENIC (vol. i. p. 301). A full account of the different forms of As obtained, along with As_2O_3 , by subliming As in a tube is given by Petersen (*Z. P. C.* 4, 403; *abstract in C. J.* 64 [11], 570 [1893]). Petersen gives the following heats of oxidation, and atomic volumes, of the allotropic forms of As (*Z. P. C.* 8, 601 [1891]):—

	[As ^o D°]	At. volume
Grey, rhombohedral	156,880	18.1
Grey-black, amorphous	154,840	15.94
Brown, amorphous	163,500	15.99

Arsenic, bromide of (vol. i. 309). AsBr_3 combines with NH_3 to form $\text{AsBr}_3 \cdot 3\text{NH}_3$ (Besson, *C. R.* 110, 1258 [1890]).

Arsenates (vol. i. p. 307). For arsenates of Cd v. A. de Schulten (*Bl.* [3] 1, 478 [1889]); for arsenates of Cu, and of Cu and Na, v. Hirsch (*C. C.* 1891 [1]. 15; *abstract in C. J.* 60, 644); many double arsenates of K, and of Na, with Cd, Co, Mg, Mn, Ni, and Zn are described by Lefèvre (*C. R.* 110, 405 [1890]).

For *thio-arsenates* of Cu, Hg, Zn, and Zn and Na, v. Preis (*A.* 257, 178 [1890]).

Arsenites (vol. i. p. 306). For the preparation, by double decomposition from the salt $2\text{KAsO}_4 \cdot \text{As}_2\text{O}_3$, and properties, of the arsenites of the following metals v. Reichard (*B.* 27, 1019 [1894]):—Al, Ba, Cd, Ca, Cr, Co, Cu, Au, Fe, Pb, Mg, Mn, Hg, Ni, Pd, Pt, Ag, Sr, Sn, Ti, U, and Zn (references and criticisms of former investigations are given). Stavenhagen (*Zeit. f. angew. Chemie*, 1894. 165) obtained the double salt of K arsenite and sulphate, $\text{K}_2\text{AsO}_3 \cdot 10\text{K}_2\text{SO}_4$, by evaporating solutions of the constituents after mixing.

Arsenic acid (vol. i. p. 307). For a detailed account of the reaction of H_2S with solutions of H_3AsO_4 v. Brauner a. Tomeetchek (*C. J.* 53, 145 [1888]).

Arsenious chloride (vol. i. p. 310). According to Besson (*C. R.* 109, 940 [1889]), AsCl_3 solidifies at -18° , forming white needles; at -30° AsCl_3 absorbs much Cl, forming a liquid which does not solidify at -60° , and which with water gives off much Cl and forms As_2O_3 . Besson (*C. R.* 110, 1258 [1890]) says that the compound formulated by Rose as $2\text{AsCl}_3 \cdot 7\text{NH}_3$ is really $\text{AsCl}_3 \cdot 4\text{NH}_3$.

Arsenious fluoride (vol. i. p. 310). Moissan (*A. Ch.* [6] 19, 280 [1891]) prepared AsF_3 by heating As_2O_3 with HF; he gives b.p. as 63° at 750 mm., and says that it solidifies to white crystals at -8.5° . Besson (*C. R.* 110, 1258 [1890]) describes the compound $2\text{AsF}_3 \cdot 5\text{NH}_3$.

Arsenic, trihydride of (vol. i. p. 310). Brunn (*B.* 22, 3202 [1889]) finds that the first products of the action of air, or O, on AsH_3 are solid $n\text{AsH}$ and H_2O , and the next products are As and H_2O . AsH_3 and H_2S do not react in absence of air at the ordinary temperature, either as gases or in solution (*B., l.c.*). AsH_3 begins to decompose at c. 230° (*B., l.c.*). For the reactions of AsH_3 with AgNO_3 v. Vitali (*abstract in C. J.* 64 [11] 206 [1893]).

Arsenious iodide (vol. i. p. 311). Besson (*C. R.* 110, 1258 [1890]) describes the compounds $\text{AsI}_3 \cdot 4\text{NH}_3$ and $\text{AsI}_3 \cdot 12\text{NH}_3$.

Arsenious sulphide (vol. i. p. 315). Picton (*C. J.* 61, 140, 144 [1892]) obtained an aqueous solution of colloidal As_2S_3 , containing also some very finely divided sulphide in suspension, by allowing As_2O_3 to flow into saturated H_2SAq , into which H_2S was continually passing, and removing H_2S by a stream of H.

Arsenic pentasulphide (vol. i. p. 315) As_2S_5 is obtained, according to McCay (*Am.* 12, 547 [1891]), by passing H_2S for a long time into a hot solution of an alkali dihydrogen arsenate, and then prg. by a mineral acid.

Arsenic, thiochlorides and thio-iodides of (vol. i. p. 316). Ouvrard (*C. R.* 116, 1516 [1893]) obtained $\text{As}_2\text{S}_2\text{Cl}_2$ by passing H_2S into

AsCl_3 , and washing the pp. with CS_2 . By heating 1 pt. As_2S_3 with 10 pts. AsCl_3 to 150° he obtained AsSCl .

AZO-IMIDE (*v. Hydrasoic acid*, p. 919, *Addenda*).

BARIUM (vol. i. p. 440). Richards, in 1893, made an elaborate experimental revision of the at. w. of Ba (*P. Am. A.* 28, 1; 29, 55). As a mean result of the most trustworthy experiments, R. adopts 137.1 as the at. w. of Ba ($O=15.96$). Limb (*C. R.* 112, 1434 [1891]) failed to obtain any Ba by electrolysis fused BaCl_2 , or BaCl_2 mixed with NaCl .

Barium, carbide of. By heating a mixture of Ba amalgam and powdered charcoal in H, Maquenne (*C. R.* 114, 361 [1892]) obtained grey BaC_2 ; decomposed by water, giving BaO , H_2Aq and C_2H_2 ; *v. also* Moissan, *C. R.* 118, 683 (*abstract in C. J.* 66 [1], 314 [1891]).

Barium, chloride of (vol. i. p. 441). By bringing BaCl_2 into contact with liquid NH_3 , and allowing the gas to escape at 0° and 760 mm., Joannis obtained $\text{BaCl}_2 \cdot 8\text{NH}_3$ (*C. R.* 112, 337 [1891]).

Barium, fluoride of (vol. i. p. 441). BaF_2 is obtained in microscopic crystals by adding $\text{BaCl}_2 \cdot \text{Aq}$ (3.6 p.c.) to boiling KFAq (1 p.c.), boiling, washing, drying, and heating strongly (Moissan, *B.* [3] 5, 152 [1891]). Pouleno (*C. R.* 116, 987 [1893]) obtained BaF_2 in well-formed octahedra by fusing amorphous BaF_2 with KHF_4 and KCl .

Barium, nitrides of. Maquenne (*C. R.* 114, 220 [1892]) obtained a mixture, probably containing some Ba_3N_2 , by heating Ba amalgam to redness in a current of N. Berthelot a. Matignon (*A. Ch.* (7) 2, 144 [1894]) say that Ba_3N_2 is formed by heating $\text{AmN}_3 \cdot \text{Aq}$ with BaO , H_2Aq .

Barium monoxide (vol. i. p. 442). BaO is unchanged at c. 1750° (Read, *C. J.* 65, 313 [1894]); it liquefies at c. $2,000^\circ$, but is not decomposed at c. $2,500^\circ$ (Moissan, *C. R.* 115, 1034 [1892]).

Barium dioxide (vol. i. p. 443). BaO_2 is decomposed by salts of Al, Cr, Co, Fe, &c.; some salts—*e.g.* those of Ca, Li, K, Na—do not react with BaO_2 (*v. Kwasnik, B.* 25, 65). For decomposition of BaO_2 by heat *v. Le Chatelier* (*C. R.* 115, 654; *abstract in C. J.* 64 [1], 71 [1893]).

BERYLLIUM (vol. i. p. 504). Krüss a. Morahit (*B.* 23, 727 [1890]) obtained hexagonal crystals of Be, mixed with BeO , by heating $\text{BeF}_2 \cdot 2\text{KF}$ to redness with Na. K. a. M. (*l.c.* p. 2552) obtained the value 9.03 for the at. w. of Be by converting BeO into $\text{BeSO}_4 \cdot 4\text{H}_2\text{O}$, and this again to BeO . Gibson (*C. J.* 63, 909 [1893]) describes methods for preparing BeO from *beryl*.

Beryllium, fluoride of (vol. i. p. 506). Petersen (*Z. P. C.* 5, 263 [1890]) gives the thermal data $\text{H.F.} [\text{BeO} \cdot \text{H}_2\text{O} \cdot 2\text{HFAq}] = 19,683$. The *double compound* $\text{BeF}_2 \cdot 2\text{AmF}$ is described by H. von Helmholt (*Zeit. f. anorg. Chemie*, 3, 115 [1893]).

Beryllium, oxide of (vol. i. p. 506). By dissolving BeO in KOH , Krüss a. Morahit (*B.* 23, 727 [1890]) obtained *potassium beryllate* $\text{BeO}_2 \cdot \text{K}_2$ (?), mixed with K_2CO_3 , as a snow-white, silky solid.

BISMUTH (vol. i. p. 509). The at. w. of Bi was re-determined by Classen in 1890 (*B.* 23, 938 [1890]), by converting Bi into nitrate, and

this into Bi_2O_3 ; the mean result was 208.38 ($O=15.96$). Schneider (*J. pr.* [2] 42, 558; 44, 23 [1891]) criticises Classen's results, and maintains that Marignac's value (almost exactly 208) is as trustworthy as that obtained by C. The molecule of Bi in dilute solution in tin is perhaps diatomic (?) (Heycock a. Neville, *C. J.* 57, 376 [1890]).

Preparation.—Classen (*l.c.*) says that pure Bi is best prepared by electrolysis a solution of the metal in $\text{HNO}_3 \cdot \text{Aq}$, using a cone of Pt as the negative electrode, then washing with alcohol, and fusing with KCy .

Properties.—Melts at 264° , according to Classen (*l.c.*); at 269.22° , according to Callendar a. Griffiths (*C. N.* 63, 1 [1831]). S.G. 9.7474 (*C.*, *l.c.*; no temperature given); 9.787 at 0° , 9.673 solid at the m.p., 10.004 liquid at the m.p. (Vicentini, *Rend. Acad. Lincei*, 6 [11], 121, 147 [1891]). For S.G. of liquid Bi from 235° to 280° *v. Cattaneo* (*Rend. Acad. Lincei*, 7 [11], 88 [1892]). For electrical resistance *v. E. v. Aubel* (*C. R.* 103, 1102 [1889]).

Reactions.—According to Veley (*Pr.* 43, 458 [1891]), Bi does not dissolve in 30 p.c. $\text{HNO}_3 \cdot \text{Aq}$ at 30° if HNO_2 is absent; but Bi dissolves readily in 1 p.c. $\text{HNO}_3 \cdot \text{Aq}$.

Bismuth, bromide of (vol. i. p. 511). BiBr_3 boils at 453° (V. Meyer, *A.* 264, 122 [1891]). Cavazzi a. Tivoli (*G. Z.* [11], 306 [1892]) describe a lustrous, black, hygroscopic solid, $\text{PbBr}(\text{BiBr}_2)_3$, obtained by allowing BiBr_3 to fall gradually into PH_3 (*abstract in C. J.* 62, 279).

Bismuth, chloride of (vol. i. p. 512). Boils at 435° – 441° (uncor.) (V. Meyer, *l.c.*). The only *double chloride* of Bi and K of those hitherto described that exists is $\text{BiCl}_2 \cdot 2\text{KCl}$. 2aq, according to Brigham (*Am.* 14, 164 [1892]). B. has also prepared $\text{BiCl}_2 \cdot \text{KCl}$ aq.

Bismuth, fluoride of (vol. i. p. 512). H. von Helmholt describes the *double fluoride* $\text{BiF}_2 \cdot \text{AmF}$ (*Zeit. f. anorg. Chemie*, 3, 115 [1893]).

Bismuth, iodide of (vol. i. p. 513). Astre (*C. R.* 110, 525 [1890]) obtained the *double iodide* $2\text{BiI}_3 \cdot \text{KI}$ by keeping I, KCl , Bi, and water in contact for some weeks, and then crystallising from Et acetate.

Bismuthous oxide (vol. i. p. 513). Classen (*B.* 23, 938 [1890]) gives S.G. as 9.044. Read (*C. J.* 65, 313 [1894]) found Bi_2O_3 to be unchanged at c. 1750° .

Bismuth, oxysulphide of (vol. i. p. 516). By passing dry H_2S into boiling benzene containing Bi_2O_3 in suspension, P. v. Scherpenberg (*C. C.* 1889, [11] 648) obtained $\text{Bi}_2\text{O}_3 \cdot \text{S}$.

Bismuth, selenide of (vol. i. p. 516). The *double compound* $\text{Bi}_2\text{Se}_3 \cdot \text{K}_2\text{Se}$ is described by P. v. S. (*l.c.*).

Bismuth, sulphide of (vol. i. p. 516). P. v. S. (*l.c.*) obtained the *double compound* $\text{Bi}_2\text{S}_3 \cdot \text{K}_2\text{S}$ by fusing Bi_2O_3 with K polysulphide.

BOBON (vol. i. p. 524). The at. w. of B has been determined by Abrahall by the analysis of BBr_3 (*C. J.* 61, 650 [1892]); the value obtained was 10.67 ($O=15.96$). Also by Ramsay a. Aston (*C. J.* 63, 207 [1893]) by finding the percentage of water in crystallised borax, and by distilling fused borax with HClAq and $\text{CH}_3 \cdot \text{OH}$, and weighing the residual NaCl ; the values varied about 11, but showed considerable differences.

Rimbach (*B.* 26, 164 [1893]), by titrating solutions of borax with standard HClAq, using methyl orange as indicator, obtained the value 10.91 (O = 15.96). The following values for S.H. of amorphous B are given by Moissan (*C. R.* 116, 924 [1893]): 0° to 100° = 3066, 0° to 192° = 3407, 0° to 234° = 3573. For atomic refraction of R. v. Ghira (*G. Z.* 23 [1], 452; *abstract in C. J.* 64 [11], 517 [1893]).

Preparation.—According to Moissan (*C. R.* 114, 319 [1892]), the methods employed to give amorphous boron yield substances containing from c. 45 to c. 72 p.c. of B. M. (*l.c.* p. 392) says that nearly pure amorphous B is obtained by heating to redness a mixture of one pt. powdered Mg with 3 pts. fused B₂O₃, washing with HClAq, KOH in alcohol, HFaq, and water (the process is tedious, details are given); by fusing this product with 50 pts. B₂O₃, and washing with HClAq &c., a brown powder is obtained containing c. 98.5 p.c. B, with traces of Mg and small quantities of other impurities.

Properties and Reactions.—The properties of amorphous boron are described by Moissan (*C. R.* 114, 617 [1892]). Brown powder; S.G. 2.45. Does not fuse in electric arc, but volatilises (M., *C. R.* 117, 423 [1893]); increases in density when heated to c. 1500° in H. Specific electrical resistance = 801 megohms. Burns in air at c. 700°. Combines directly with Br, Cl, (not I), N at c. 1200°, Se, S, (not Te); also with Al, Fe, Mg, Pt, and Ag. Reduces many oxyacids and oxides when heated therewith; HClO₄, HIO₃, HNO₃, and H₂SO₄ are readily reduced; As₂O₃ and As₂O₅, CO, N₂O, P₂O₅, SiO₂, steam, and SO₂ are also reduced; many metallic oxides are reduced to metals, often with explosive violence; molten KOH gives off H; metallic fluorides are generally decomposed, giving BF₃; many other metallic salts, both in solution and when heated as solids, are reduced by amorphous boron.

Boron, bromide of (vol. i. p. 525). BBr₃ boils at 90° (Freyer a. V. Meyer, *Zeit. f. anorg. Chemie*, 2, 1). Ghira (*Z. P. C.* 12, 768 [1893]) gives S.V. 94.72; and S.G. $\frac{D_4}{20} = 2.64985$. According to Besson (*C. R.* 112, 1001 [1891]), when a mixture of gaseous HI and BBr₃ is passed through a glass tube at 300°–400° the products are BBr₃I, BBr₂I₂, and BI₃. BBr₃I and BBr₂I₂ are colourless liquids, distilling at c. 125° and 180°; they are rapidly decomposed by air and light. Tarble (*C. R.* 116, 1521 [1893]) says that BBr₃ combines with PBr₃ and PBr, to form compounds easily decomposed by water, Cl, or NH₃ in the cold. Besson (*C. R.* 114, 542 [1892]) describes BBr₃.4NH₃, obtained by passing dry NH₃ into BBr₃ in dry CCl₄ at 0°.

Boron, carbide of, B₂C. Moissan (*C. R.* 118, 556 [1894]) says that B and C combine when amorphous B is mixed with c. $\frac{1}{3}$ its weight of sugar charcoal, and the mixture is heated in the electric furnace for some minutes, using a current of 250–300 ampères and 70 volts. After treating the product with HNO₃Aq, and then with KClO₄ and HNO₃Aq, the carbide remains as a very hard, lustrous, black, crystalline powder; S.G. 2.51; burns very slowly in O at c. 1000°; acted on by Cl below 1000°, but not by Br, I, S, P, N, or mineral acids; reacts with molten KOH or KNaCO₃ (*abstract in C. J.* 66 [11], 279 [1894]).

Boron, chloride of (vol. i. p. 525). BCl₃ boiling at 17° (Freyer a. V. Meyer, *Zeit. f. anorg. Chemie*, 2, 1). Ghira (*Z. P. C.* 12, 768 [1893]) gives S.G. $\frac{D_4}{20} = 1.43386$, and S.V. 81.94.

Boron, fluoride of (vol. i. p. 526). According to Besson (*C. R.* 110, 80 [1890]), BF₃ unites with PH₃ at c. –80° to form 2BF₃.PH₃, decomposed by water giving off H and PH₃.

Ammonium borofluoride is described by Stolba (*C. C.* 1890. [1] 211; *abstract in C. J.* 58, 560).

Boron, hydride of (vol. i. p. 526). Sabatier (*C. R.* 112, 865 [1891]) says that the gas produced by adding HClAq to the brown powder formed by heating B₂O₃ with Mg in H has a very disagreeable odour, burns with a green flame, gives a brown pp. with AgNO₃Aq, deposits B when passed through a glass tube at a dull red heat (H coming off), and is decomposed by electric sparks, giving pure H. The gas contains a little B hydride, according to S. (*l.c.*); cf. Winkler (*B.* 23, 772 [1890]).

Boron, iodide of (vol. i. p. 527). BI₃. Prepared by Moissan (*C. R.* 112, 717 [1891]), (1) by heating I and B to 700°–800°; (2) by heating amorphous B (dried in H at 200°), in a stream of dry HI, in a tube of hard glass until the glass nearly softens; (3) by passing HI and BCl₃ vapours through a porcelain tube heated to redness. The product is dissolved in CS₂, shaken with Hg, and allowed to crystallise. Colourless crystals, very hygroscopic, rapidly become coloured in light. Melts at 48° and boils at 210°. Decomposed by water, giving HIAq and H₂BO₃Aq. (For other reactions *v. abstract in C. J.* 60, 979 [1891]). For compounds with NH₃ *v.* Besson (*C. R.* 114, 542 [1892]; *abstract in C. J.* 62, 771).

Boron, oxide of (vol. i. p. 527). B₂O₃. For reduction by Mg powder, giving Mg boride, *v.* Winkler (*B.* 23, 772 [1890]). The compound B₂O₃.P₂O₅ (=BPO₃) is obtained by evaporating H₂BO₃Aq mixed with H₂PO₄, heating to redness, and washing with hot water. (G. Meyer, *B.* 32, 2919 [1889]).

Borates (vol. i. p. 529). For some new borates of Li, Rb, and Cs *v.* Reischle (*Zeit. f. anorg. Chemie*, 4, 166 [1893]). For remarks on the classification of alkali and alkaline earth borates *v.* Le Chatelier (*C. R.* 113, 1034 [1891]). For a full account of Mn borate, *v.* Hartley a. Ramage (*C. J.* 63, 129 [1893]). The compounds 6FeO.FeBr₃.8B₂O₃ and 6ZnO.ZnBr₂.8B₂O₃ are described by Rousseau a. Allaire (*C. R.* 116, 1445; *abstract in C. J.* 64 [11], 518 [1893]).

Boron, phosphide of. According to Besson (*C. R.* 113, 78 [1891]), a phosphide of B is obtained by passing PH₃ into BBr₃, and heating the product, BBr₃.PH₃, to 300°, when it gives HBr and B phosphide. The phosphide is said to be a brown powder, insoluble in water, reacting with boiling conc. alkali solutions to give PH₃; gives off P when heated to redness in N (for other reactions *v. abstract in C. J.* 60, 1418 [1891]).

Boron, selenide of. (B₂Se₃). Obtained, as a yellowish grey powder, decomposed violently by water, giving H₂Se and some Se, by heating B to full redness in a current of H₂Se (Sabatier, *C. R.* 112, 1000 [1891]).

Boron, sulphides of (vol. i. p. 531). For heat of formation of B_2S_3 , v. Sabatier (*C. R.* 112, 862; *abstract in C. J.* 60, 981 [1891]). Moissan (*C. R.* 115, 203 [1892]) gives details of various methods of preparing B_2S_3 , and describes the reactions of this compound (v. *abstract in C. J.* 62, 1393 [1892]). According to M. (*l.c.* p. 271), *boron pentasulphide*, B_2S_5 , is obtained by heating BI_3 with rather less than one equiv. of S in CS_2 solution at 60° for many hours. M. describes the compound, which was not obtained pure, as a light white crystalline powder, S.G. 1.85.

BROMHYDRIC ACID (vol. i. p. 532). The V.D. has been determined by Biltz at -15° and -28° (*Z. P. C.* 10, 354 [1892]); the results agree with the V.D. required by the formula HBr. The M. Ms of HBrAq from 15.47 to 65.69 p.c. HBr have been measured by Perkin (*C. J.* 55, 706 [1889]).

Preparation.—1. By the interaction of P, Br, and H_2O , v. Fileti a. Crosa (*G.* 21, 64 [1891]; cf. Gassman, *abstract in C. J.* 64 [11], 453 [1893]). 2. By passing H_2S into Br covered with water (Recoura, *C. R.* 110, 784 [1890]).—3. By adding H_2SO_4 Aq S.G. 1.41 to KBr (Feit a. Kubiersohky, *J. Ph.* [5] 24, 159; *abstract in C. J.* 60, 1320 [1891]; v. also Addyman, *C. J.* 61, 97 [1892]; and cf. Léger, *abstract in C. J.* 64 [11], 114 [1893]).

Hydrates.—Pickering (*P. M.* [5] 36, 11 [1894]) has isolated $HBr \cdot 3H_2O$ and $HBr \cdot 4H_2O$; the former melting at -48° and the latter at -55.8° .

Reactions.—For the decomposition of HBrAq by H_2SO_4 Aq of different concentrations v. Addyman (*C. J.* 61, 98 [1892]).

BROMINE (vol. i. p. 534). Mol. w. in solution in water or acetic acid = 159.5 (Br.) (Paterno a. Nasini, *B.* 21, 2154 [1888]). The V.D.s of Br from 15° to 280° , and at pressures from 15 to 760 mm., have been determined by Ferman (*Pr.* 48, 45 [1891]); no indications of dissociation were obtained. For measurements of the absorption of light by Br v. Camichel (*C. R.* 117, 307; *abstract in C. J.* 64 [11], 561 [1893]).

Bromates (vol. i. p. 538). *Lithium bromate* $LiBrO_3$; prepared by the interaction of $Ba(BrO_3)_2$ Aq and Li_2SO_4 Aq (Potilitzin, *J. R.* 22, 392; *abstract in C. J.* 62, 1275 [1892]). *Potassium bromate* $KBrO_3$. The decomposition of this salt by heat has been studied by Cook (*C. J.* 65, 802 [1894]); decrepitation occurs at c. 180° , with evolution of Br; the salt fuses at a higher temperature, and O is evolved, without any Br, until KBr remains; no oxy-compounds are formed.

Strontium bromate begins to decompose at c. 240° ; the principal change is to $SrBr_2$ and O, but SrO is also formed (Potilitzin, *J. R.* 22, 454; *abstract, with summary of quantitative results, in C. J.* 64 [11], 11 [1893]).

CADMIUM (vol. i. p. 654). Determinations of the at. w. have been made by Partridge (*Am. S.* [3] 40, 877 [1891]), and by Morse a. Jones (*Am.* 14, 261 [1892]). P. converted $CdCl_2$ into CdO by heating, $CdSO_4$ into CdS by heating in H_2S , and CdC_2O_4 into CdS by heating in H_2S . M. a. J. converted Cd into $Cd(NO_3)_2$, and this into CdO by heating. The results all lie about 112 (v. *abstract in C. J.* 60, 399; cf. Clarke, *ibid.* 890 [1891], and 62, 1397 [1892]). Lorimer a. Smith

(*Zeit. f. anorg. Chemie*, 1, 364 [1892]) obtained values varying from 112.182 to 111.908 ($O=16$). The molecule of Cd in dilute solution in tin may be diatomic (v. Heycock a. Neville, *C. J.* 57, 376 [1890]). Cd melts at 320.68° , according to Callendar a. Griffiths (determined by Pt thermometer, *C. N.* 63, 1 [1891]). For the linespectrum of Cd v. Ames (*P. M.* [5] 30, 33 [1890]). According to Williams (*Am.* 14, 278 [1892]), Cd crystallises in hexagonal and polyhedral forms; axial ratio $a:c=1:1.6554$. Cd is superficially oxidised at a dull-red heat by *nitric oxide* (Sabatier a. Senderens, *C. R.* 114, 1429 [1892]). Montemartini (*G.* 22 [1] 250; v. *abstract in C. J.* 62, 1278 [1892]) has analysed the gases produced by the interaction of Cd and nitric acid; with excess of HNO_3 Aq (27.5 p.c.) at 8° , N, NO , N_2O and NH_3 are produced.

Cadmium, alloys of (vol. i. p. 655). For an alloy with gold, CdAu, v. Heycock a. Neville (*C. J.* 61, 914 [1892]; cf. *ibid.* 65, 65 [1894]). For alloys with copper, gold, and silver, prepared by immersing Cd in solutions of salts of the other metals, v. Mylius a. Fromm (*B.* 27, 630 [1894]).

Cadmium, bromide of (vol. i. p. 655). For the double compounds $CdBr_2 \cdot xCsBr$, $x=1, 2$, and 3, v. Wells a. Walden (*Zeit. f. anorg. Chemie*, 5, 266 [1893]).

Cadmium, chloride of (vol. i. p. 655). Kwasnik (*Ar. Ph.* 229, 569; *abstract in C. J.* 62, 566 [1892]) describes $CdCl_2 \cdot 2NH_3$, and $CdCl_2 \cdot NH_3$. For the double compounds $CdCl_2 \cdot xCsCl$ and $CdCl_2 \cdot 2CsCl$, v. Wells a. Walden (*l.c.*). Double compounds with HCl , NH_4Cl , $LiCl$, and KCl , of the form $CdCl_2 \cdot MCl$, are described by Chassevant (*A. Ch.* [6] 30, 5; v. *abstract in C. J.* 66 [11], 18 [1894]).

Cadmium, fluoride of (vol. i. p. 655). CdF_2 is obtained by (1) the interaction of HF and Cd at a red heat; (2) the interaction of HF and fused $CdCl_2$, or CdO at a red heat; it is a colourless, transparent solid; S.G. 6.64; somewhat soluble water, insoluble alcohol of 95° (Poulenc, *C. R.* 116, 581 [1893]).

Cadmium, iodide of (vol. i. p. 656). For the double compounds $CdI_2 \cdot xCsI$, when $x=1, 2$, and 3, v. Wells a. Walden (*l.c.*).

Cadmium, oxides of (vol. i. p. 656). CdO is unchanged at c. 1750° (Read, *C. J.* 65, 313 [1894]).

According to Kouriloff (*J. R.* 22, 171; *abstract in C. J.* 62, 1278 [1892]), the compound $CdO \cdot CdO \cdot H_2$ is obtained by heating $CdO \cdot H_2$ with H_2O Aq. Morse a. Jones (*Am.* 12, 488; *abstract in C. J.* 58, 1376 [1890]) obtained small crystals, which they say were cadmous oxide Cd_2O , by gently heating $CdOH$; the hydroxide was obtained by heating $CdCl_2$, $CdBr_2$, or CdI_2 , with excess of Cd, to the melting-point, in N, or *in vacuo*, and treating with water, when $CdCl_2$, $CdBr_2$, or CdI_2 dissolved, a little CdC_2O_4 separated, and $CdOH$ remained as a white amorphous powder.

Cadmium, salts of (vol. i. p. 656). For the electrical conductivities of very dilute solutions of $CdBr_2$, $CdCl_2$, CdI_2 , K_2CdI_4 , $Cd(NO_3)_2$, and $CdSO_4$, v. Wersshoven (*Z. P. C.* 5, 481 [1890]).

Cadmium, sulphide of (vol. i. p. 657). Two forms (and perhaps more) of CdS seem to exist, one lemon-yellow and the other red; they differ

slightly in S.G., and in crystalline form; the yellow is said to change to the red by friction (*v.* Buchner, *Chem. Zeit.* 11, 1087, 1107; 15, 778; *von Klobukoff, J. pr.* [2], 89, 412; *abstracts in C. J.* 54, 224 [1888]; 56, 946 [1889]; 62, 778 [1892]). A solution of colloidal CdS was obtained by Prost (*C. C.* 1888, 32; *abstract in C. J.* 54, 653 [1888]) by completely ppg. an ammoniacal solution of CdSO₄ by H₂S, washing well, suspending the pp. in water and passing in H₂S. A solution with 4 grms. CdS per litre remained clear for many days; one with 11 grms. coagulated in 24 hours.

CÆSIUM (vol. i. p. 657). According to Beketoff (*v. abstract in C. J.* 62, 274 [1892]), Cs is obtained by heating CsOH with c. $\frac{1}{4}$ its weight of Al.

Cæsium, haloid compounds of (vol. i. p. 658). A series of compounds of the form CsX_n, where X_n = Br_n, I_n, or Br and I, Cl, Br and I, &c., is described by Wells a Penfield (*Am. S.* [3] 43, 17; *abstract in C. J.* 62, 778 [1892]). Double compounds of Cs haloids with haloid compounds of Cd, Cu, Mg, Hg, Pb, and Zn are described by Wells (and others) (*Am. S.* [3] 4, 221; *Zeit. f. anorg. Chemie*, 8, 195; 5, 266, 273, 300, 304, 306; *abstracts in C. J.* 64 [11], 67, 322 [1893]; 66 [11], 45, 47 [1894]).

Cæsium, hydroxide of (vol. i. p. 658). S.G. $\frac{0}{4}$ 4.0178; [CsOH, Aq] = 15,876; [CsOHAq, HClAq] = 18,790 (Beketoff, *C. C.* 1891. [11] 451).

Cæsium, oxide of (vol. i. p. 658). According to Beketoff (*J. R.* 25, 433; *abstract in C. J.* 66 [11], 234 [1894]), Cs₂O reacts with slightly moist H to give Cs and CsOH.

CALCIUM (vol. i. p. 663). The molecule in dilute solution in tin may be diatomic (*v.* Heycock a Neville, *C. J.* 57, 376 [1890]).

Calcium, carbide of. By heating 120 g. CaCO₃ with 70 g. sugar charcoal in the electric furnace with a current of 350 amperes and 70 volts, Moissan (*C. R.* 118, 501 [1894]) obtained lustrous, yellow crystals of CaC₂; S.G. 2.22 at 18°; insoluble in most solvents; reacts with Cl, Br, and I at 250°-350°; burnt to CaCO₃ by O at a red heat; interacts violently with water, giving off pure acetylene, and with steam giving CaCO₃, C, H, and C₂H₂ (*abstract in C. J.* 66 [1], 318 [1894]).

Calcium, oxide of (vol. i. p. 666). CaO is unchanged at c. 1750° (Read, *C. J.* 65, 318 [1894]). According to Veley (*C. J.* 63, 821 [1893]; 65, 1 [1894]), dry CaO does not appreciably combine with dry CO₂, SO₂, or Cl below 300°. Baker (*C. J.* 65, 611 [1894]) says that dry CaO does not react with dry SO₂, nor with dry NH₄Cl. Moissan (*C. R.* 115, 1034 [1892]) obtained crystals of CaO by heating ordinary lime in the electric furnace.

Calcium, oxychloride of (vol. i. p. 666). Prepared by boiling CaO with conc. CaCl₂Aq; crystallises in thin, lustrous needles; decomposed by water, alcohol, &c.; dissolves in glycerin. Composition is probably 3CaO.CaCl₂.15aq (Zahorsky, *Zeit. f. anorg. Chemie*, 3, 34 [1893]).

Calcium, oxyiodide of. By heating CaO with CaI₂Aq in a sealed tube at 150° for 6 hours, Tassilly (*Bull.* [3] 9, 629 [1893]) obtained needles of CaI₂.3CaO.16aq.

CARBON (vol. i. p. 684).

Diamond. Moissan (*C. R.* 116, 318; 118, 320; *abstracts in C. J.* 64 [11], 275; 66 [11], 189 [1893 and 1894]) obtained grey-black carbonado by dissolving C in iron, heating to 2000°-3000°, and rapidly cooling the exterior by water or by plunging into a bath of melted lead; the liquid interior expands as it cools and produces a very high pressure. Diamond blackens, swells, and changes to graphite in the electric furnace (*M., C. R.* 117, 428 [1893]). For various reactions of diamond, *v.* Moissan (*C. R.* 116, 460; *abstract in C. J.* 64 [11], 319 [1893]).

Graphite. For accounts of graphites prepared in different ways, the compositions of the graphitic oxides obtained, and the H.F.s of these oxides, *v.* Berthelot a Petit (*C. R.* 110, 101, 106; *abstract in C. J.* 68, 448 [1890]). For the action of conc. HNO₃ on various graphites, *v.* Luzi (*B.* 24, 4085; 26, 1412 [1892 and 1893]).

Amorphous carbon. Mixer (*Am. S.* [3] 45, 363; *abstract in C. J.* 64 [11], 571 [1893]) describes the interactions of charcoal and N, S, O, and the halogens. According to Ernst (*J. pr.* [2] 48, 31; *abstract in C. J.* 64 [11], 461 [1893]), the composition of the products of combustion of coke (CO and CO₂) depends almost wholly on the temperature; the maximum formation of CO₂ is at c. 700°, at 1,000° CO is the only product.

Allotropy of carbon. The following heats of combustion, and atomic volumes, are given by Petersen (*Z. P. C.* 8, 601 [1891]):—

	[C, O ₂]	At. volume.
Amorphous . . .	96,530 to 96,980	6.7 to 8
Graphite . . .	93,360	5.8
Diamond . . .	93,240 to 94,550	3.4

For the reactions of various forms of C with K₂Cr₂O₇ and H₂SO₄, *v.* Wiesner (*M.* 13, 371; *abstract in C. J.* 62, 1278 [1892]); and with HNO₃ and KClO₄, *v.* Schutzenberger (*C. R.* 111, 774; *abstract in C. J.* 60, 265 [1891]).

Carbon, tetrabromide of (vol. i. p. 688). Collie (*C. J.* 65, 262 [1894]) finds that very many compounds of carbon give CBr₄ when heated with NaOH Aq and Br.

Carbon, bromochlorides of (vol. i. p. 688). The three compounds CBrCl₃, CBr₂Cl₂, and CBrCl₂ are formed by heating CHCl₃ and Br to 225° in a sealed tube (Besson, *C. R.* 114, 222 [1892]).

Carbon, tetrafluoride of, CF₄. Mol. w. 88.87. V.D. 44.6. Prepared by the direct union of C (purified lampblack) and F at the ordinary temperature; by the reaction of F with CCl₄, slightly heated, or with CHCl₃ at 100°, or with CH₄ (Moissan, *C. R.* 110, 296, 951; *abstracts in C. J.* 58, 557, 944 [1890]); also by heating AgF with CCl₄ to 220° in a sealed tube (Chabrie, *C. R.* 110, 279 [1890]). M. recommends to pass vapour of CCl₄ over AgF at 195°-200°, to let the vapours pass through a serpentine tube kept at -23°, and to collect the gas over Hg; the gas is kept in contact with fragments of caoutchouc (to remove CCl₄), then shaken with absolute alcohol, in which it dissolves, and then expelled by heat, collected and shaken with H₂SO₄ (to remove alcohol vapour); metal vessels must be used. CF₄ is a colourless gas, liquefying at -15° and 760 mm. pressure, or at 20° under

a pressure of 4 atmos. Other fluorides seem to be formed along with CF_4 ; Chabrie (L.c.) says that AgF and C_2Cl_4 yield C_2F_4 .

Carbon, tetra-iodide (of vol. i. p. 689). Moissan (C. R. 118, 19; *abstract* in C. J. 60, 1420 [1891]) prepares OI_4 by heating OCl_4 (free from OHCl_4) with excess of BI_3 to 90° in a sealed tube, washing the crystals with NaHSO_4Aq , drying, and slowly subliming *in vacuo*. OI_4 reacts with Cl to form COCl_2 and chlorides of I ; reduced to CHI_3 by H at 140° (for other reactions v. M., l.c.).

Carbon monoxide (vol. i. p. 689). For some experiments on the sparking of CO , with the formation of brown solids, v. Berthelot (C. R. 110, 609) and Schutzenberger (C. R. 110, 560; *abstracts* in C. J. 58, 691 [1890]). Winkler (B. 24, 878 [1891]) finds that CO is reduced to C , at a full red heat, by Mg ; carbides of Mg are probably formed (*cf.* W., B. 23, 2642 [1890]).

Carbon dioxide (vol. i. p. 691). For S.H. of CO_2 , v. Kurnakoff (J. R. 22, 498; *abstract* in C. J. 64 [11], 5 [1893]). CO_2 is reduced by heating to redness with Mg , amorphous C and some CO being formed (Winkler, B. 23, 2642; 24, 878 [1890-91]). Dry CO_2 is said not to combine with dry NH_3 (Hughes a. Soddy, C. N. 69, 389).

Carbon, oxychloride of (vol. i. p. 692). COCl_2 becomes viscid, but remains clear, at -75° (Haase, B. 26, 1052 [1893]).

Carbon disulphide (vol. i. p. 693). The contractions observed when mixtures of CS_2 and air are exploded show that the reaction is more complicated than is shown by the equation $\text{CS}_2 + 8\text{O}_2 = \text{CO}_2 + 2\text{SO}_2$; the volume of CO_2 found is, practically, in accordance with the equation, but the volume of SO_2 is smaller; some of the N of the air is oxidised (v. Pedler, C. J. 57, 625 [1890]). By heating CS_2 with excess of *aqua regia*, Schlagdenhauffen a. Bloch (J. Ph. [5] 28, 241 [1893]) obtained $\text{SO}(\text{OCCl})\text{Cl}$. Decomposition of CS_2 , heated in dry N , begins at 216° , and explosion with O at a higher temperature (Baker, C. J. 65, 611 [1894]).

Tricarbon disulphide C_3S_2 . B. von Lengyel (B. 26, 2960 [1893]) obtained this compound by keeping the vapours of CS_2 in an electric arc between C poles for some hours, filtering off the black substance formed, allowing the red filtrate to stand over Cu for 6 to 8 days, and evaporating in a current of dry air. C_3S_2 is a deep-red liquid, S.G. 1.27889; the vapour, even in minute quantities, causes violent catarrh; can be distilled, with partial change to a black solid, at 60° - 70° and reduced pressure; insoluble water, but dissolved by EtOH , Et_2O , CS_2 , OHCl_3 , or C_2H_5 . A conc. solution in CS_2 deposits a black solid; the same solid is formed by gently heating the liquid, if heating to 100° - 120° is rapid the change is explosive. The black solid is probably a polymeric. A solution of C_3S_2 in CS_2 reacts with Br to form $\text{C}_3\text{S}_2\text{Br}_2$. (For other reactions, v. *abstract* in C. J. 66 [11], 91 [1894].)

Carbon, thiobromide of, $\text{C}_3\text{S}_2\text{Br}_2$; formed by the action of Br on a solution of C_3S_2 in CS_2 (v. *supra*).

Carbon, thiochloride of (vol. i. p. 695). The polymeric of thio-carbonyl chloride has the molecular formula $(\text{SCl}_2)_n$, according to the

cryoscopic determinations of Carrara (G. 28 [11] 12; *abstract* in C. J. 66 [11], 15 [1894]).

CERIUM (vol. i. p. 723). For details regarding the preparation of Ce compounds free from compounds of Di and La , v. Schottländer (B. 25, 378 [1892]); also Bricout (C. R. 118, 145 [1894]).

Cerium, hydride of. According to Winkler (B. 24, 878 [1891]), a compound of Ce and H , probably CeH_3 , is formed by reducing CeO_2 by Mg in presence of H .

Cerium dioxide (vol. i. p. 725). CeO_2 is unchanged at c. 1750° (Read, C. J. 65, 813 [1894]).

CHLORHYDRIC ACID (vol. ii. p. 5). Biltz (Z. P. C. 10, 854 [1892]) finds that the V.D. at -77° agrees with the formula HCl . Perkin (C. J. 55, 703, 705 [1889]) has determined M. of HClAq and HCl in iso-amyl oxide; the values obtained for HCl in Aq are c. double those for HCl in iso-amyl oxide. For measurements of the E.C. of HCl in different solvents, v. Kablukoff (Z. P. C. 4, 429 [1889]). For revised tables giving S.G. of HClAq , v. Lunge a. Marchlewski (Zeit. f. anorg. Chemie, 1891, 183).

For the relations between the number of molecules of HCl required to ppt. one vol. of different chlorides, and the reduction of the freezing-points of solutions of the chlorides and of HCl , v. Engel (C. R. 117, 845; *abstract* in C. J. 66, 40 [1894]).

Bailey a. Fowler (C. J. 53, 755 [1888]) find that when HCl stands over P_2O_5 , the gas is absorbed, with production of POCl_3 and HPO_3 ; and that when HCl and O stand over Hg an oxychloride, probably $\text{Hg}_2\text{OCl}_2 \cdot \text{H}_2\text{O}$, is formed. Baker (C. J. 65, 611 [1894]) states that dry HCl does not combine with dry NH_3 , when the gases are mixed.

CHLORINE (vol. ii. p. 10). For the S.G. of liquid chlorine from -80° to 77° , and the vapour pressures from -88° to 1.6° , v. Knietzsch (A. 259, 100 [1890]). For the preparation of Cl for use in the laboratory, v. Klason (B. 23, 330; *abstract* in C. J. 58, 445 [1890]). Shenstone (C. J. 61, 445 [1892]) finds that Cl obtained by heating PtCl_4 always contains some HCl and O , with water, and perhaps a trace of N . Cl expands when brought into sunlight. Richardson (P. M. [5] 82, 277 [1891]) has constructed an instrument wherein the expansion is used to measure the intensity of light. Baker (C. J. 65, 611 [1894]) found that no explosion occurred when a mixture of equal vols. of dry Cl and dry H was exposed to bright sunlight; and that after exposure to bright sunshine for two days, and to diffused light for two days, more than a quarter of the mixture remained unchanged.

Pedler (C. J. 57, 618 [1890]) has examined the interaction of Cl and water in tropical sunlight; he finds that there is very little action unless there is an extremely large excess of water. With very much water and light Cl , exposed to the full light of the sun in the hot season in India, the main reaction is $2\text{H}_2\text{O} + 2\text{Cl}_2 + \text{Aq} = 4\text{HClAq} + \text{O}_2$; with diffused sunlight HClAq and HClOAq are formed at first, and finally HClAq , HClOAq , and O . Harkey (Z. P. C. 9, 678 [1892]), from an extended investigation of the explosion of mixtures of Cl , H , and O , concluded that when there is insufficient H to

combine with all the Cl and all the O, a division of the H between the Cl and O occurs; and that the product of the numbers of molecules of HCl and O, divided by the product of the numbers of molecules of H_2O and Cl, is a constant, or, in other words, that the law of Guldberg a. Waage holds good. According to Gautier a. Charpy (*C. R.* 118, 597 [1891]), there is no reaction between Mg or Zn and liquid Cl at the ordinary temperature, very little reaction with Fe or Ag, and rather more with Cu.

Chlorates (vol. i. p. 18). Spring a. Prost (*Bz.* [3] 1, 840 [1893]) have determined the quantities of Cl obtained by decomposing by heat chlorates of Al, Ba, Cu, Pb, Hg, K, Ag, Na, and Zn; the amount of Cl varied from 0.2 p.c. from $KClO_3$ to 14.45 p.c. from $Zn(ClO_3)_2$.

Calcium chlorate. Dry $Ca(ClO_3)_2$ melts between 800° – 850° , having previously given off from 8 to 5 p.c. of its weight of O; the rate of evolution of O increases, at 830° , until c. 60 p.c. of the total O is given off, after which the rate decreases. For the quantities of O evolved, of $Ca(ClO_3)_2$ decomposed, and of $CaCl_2$ and $Ca(ClO)_2$ formed, *v. abstract in J. J.* 62, 1275 [1892].

Potassium chlorate. McLeod (*C. J.* 55, 184 [1889]) concluded from his experiments that when $KClO_3$ is heated with MnO_2 , some $KMnO_4$ is formed and again decomposed (*v. MANGANESE PEROXIDE*, vol. iii. p. 183), and that Cl is always given off in this reaction. In 1893 (*B.* 26, 1790) Brunck stated that Cl is not given off when $KClO_3$ and MnO_2 are heated together, but that ozone is produced. McLeod (*C. J.* 65, 202 [1894]) has proved that Cl is produced in the reaction. Fowler a. Grant (*C. J.* 57, 272 [1890]) have studied the influence of various oxides on the decomposition of $KClO_3$ (references are given to older memoirs); they support McLeod's view of the reaction with MnO_2 , and think that the oxides of Fe, Co, Cu, and Ni react similarly to MnO_2 ; acidic oxides, such as V_2O_5 , U_2O_5 , and WO_3 , cause evolution of O accompanied by much Cl, a vanadate, uranate, or tungstate being also formed; powdered glass or sand also assists the reaction, but only when very finely divided (*v. summary of conclusions, C. J.* 57, 281–2). According to Thorpe a. Perry (*C. J.* 61, 925 [1892]), the main reaction which occurs when an intimate mixture of $KClO_3$ and iodine is heated is $2KClO_3 + I_2 = 2KIO_3 + Cl_2$, and some of the Cl reacts with unchanged I to form ICl and ICl_3 . Basset (*C. J.* 57, 760 [1890]) examined the reactions between $KClO_3$, water, and iodine; he concluded that the main reaction, at 80° , in the presence of a very small quantity of HNO_3 aq, is as shown by the equation $6I_2 + 10KClO_3 + 6H_2O + Aq = 6KHI_2O_6 + 4KClAq + 6HClAq$; in evaporating the solution to dryness Cl was given off, and the results of several experiments led to the representation of the change produced by evaporation to dryness as $12KHI_2O_6 + 8KCl + 12HCl = 11KHI_2O_6 + 9KCl + 6H_2O + ICl + ICl.HCl + 4Cl_2$. For determinations of the quantities of oxidising gases (Cl and oxides of Cl) removed by passing air through $KClO_3$ aq mixed with $HClAq$ *v. Pendlebury a. McKillop (C. S. Proc.* 1898–4. [No. 128] 211).

Strontium chlorate. For experiments on the

decomposition of this salt by heat, giving $SrCl_2$, $Sr(ClO_3)_2$, and O, *v. Potilitzin (J. R.* 21, 451; *abstract in C. J.* 58, 696 [1890]).

CHROMIUM (vol. ii. p. 152). S.H. of pure Cr (0° to 98°) = 12162 (Jäger a. Krüss, *B.* 22, 2028 [1889]). The at. w. of Cr was re-determined by Rawson in 1889 (*C. J.* 55, 218) by strongly heating $(NH_4)_2Cr_2O_7$, measuring the N given off, and weighing the Cr_2O_3 that remained; also by reducing $(NH_4)_2Cr_2O_7$ aq to $CrCl_3$ aq by $HClAq$ and alcohol, ppg. by NH_4Aq , and weighing Cr_2O_3 produced; the mean value thus obtained was 52.06, or 51.98 reduced to 0° and a vacuum ($O = 15.96$). Menieks in 1891 (*A.* 261, 839; *abstract in C. J.* 60, 882 [1891]) re-determined the at. w. of Cr by estimating (1) Ag and Cr, and also O, in Ag_2CrO_4 and in $Ag_2CrO_4.NH_3$, (2) O in $K_2Cr_2O_7$; (3) O and Cr in $(NH_4)_2Cr_2O_7$; the extreme values, from thirty-six experiments, were 52.12 and 51.83; twenty-eight of the experiments gave values between 51.9 and 52. According to Prihn (*C. R.* 116, 892 [1893]), Cr crystallises in minute cubes with pyramidal faces. For the absorption spectra of salts of Cr, *v. Lapraik (J. pr.* [2] 47, 305 [1898]).

Preparation.—Glatzel (*B.* 23, 8127 [1890]) says that almost perfectly pure Cr can be obtained by reducing $CrCl_3.KCl$ by Mg powder (for details *v. abstract in C. J.* 60, 152 [1891]). Placet (*C. R.* 115, 945 [1892]) prepares Cr by electrolysis a solution of Cr alum, containing an alkali sulphate and H_2SO_4 . Moissan (*C. R.* 116, 349 [1893]) says that Cr can be obtained by reducing a mixture of Cr_2O_3 and C in the electric furnace, using a current of 50 volts and 100 amperes, and then breaking up the product, which contains from 8.6 to 12.9 p.c. O, and heating it, mixed with more Cr_2O_3 , again in the electric furnace in a carbon crucible.

Chromic acid (vol. ii. p. 154). Miss Field (*C. J.* 61, 405 [1892]) has found that only CrO_3 is obtained by working according to Moissan's directions for preparing H_2CrO_4 . Determinations of the increase in the b.p. of water caused by solution of CrO_3 led to the conclusion that an aqueous solution of CrO_3 contains some H_2CrO_4 , and probably also $H_2Cr_2O_7$.

Chromic bromide $CrBr_3$ (vol. ii. p. 161). Reoura (*C. R.* 110, 1029, 1193) obtained green $CrBr_3.6H_2O$ by boiling saturated CrO_3 aq with a large excess of $HBrAq$ and concentrating; deliquescent crystals, soluble alcohol, insoluble ether. Unchanged when kept solid, but solution soon becomes blue and then violet, with rise of temperature. By boiling a green solution, then saturating with HBr while cold, filtering, and drying the pp. thus formed on porous plates, crystals of the blue variety, $CrBr_3.6H_2O$, were obtained; very soluble water, insol. alcohol. Heat of solution of blue crystals = 28,700; and of green = 1,860. The blue solid is changed to the green at 100° . (For more details *v. abstract in C. J.* 58, 1068 [1890].)

Chromic chloride $CrCl_3$ (vol. ii. p. 161). Marchetti (*G.* 22 [11], 875 [1892]) finds that the molecular lowering of the freezing-point of water by the violet form of $CrCl_3$ is considerably greater than that caused by the green form.

Chromic fluoride CrF_3 (vol. ii. p. 162). Fabris (*G.* 20, 582 [1890]) obtained $CrF_3.9H_2O$, as a green crystalline pp., by adding excess of

NH_4FAq gradually to a cold solution of violet $\text{Cr}_2(\text{SO}_4)_3$. Slightly sol. water; insoluble NH_4FAq or alcohol; heating in air leaves Cr_2O_3 . Poulenc (C. R. 116, 253 [1893]) obtained CrF_3 in green crystals by heating CrCl_3 , Cr_2O_3 , or $\text{CrF}_3 \cdot x\text{H}_2\text{O}$ in HF .

Chromous fluoride. According to Poulenc (l.c.), CrF_2 is formed by heating Cr to redness in HF , or by the interaction of CrCl_3 and HF at the ordinary temperature. CrF_2 , after fusion, is described as a transparent, green, crystalline mass; S.G. 4.11; slightly sol. water, insol. alcohol. Heated in air it gives Cr_2O_3 . (For more details v. abstract in C. J. 64 [11], 281 [1893].)

Chromic oxide Cr_2O_3 (vol. ii. p. 164). Moissan (C. R. 115, 1034 [1892]) found that Cr_2O_3 melted to a black mass, dotted with black crystals, in an electric furnace, using a current of 55 volts and 80 amperes.

Chromium trioxide CrO_3 (vol. ii. p. 164). For action of water v. CHROMIC ACID, p. 905. Reduced to Cr_2O_3 by NO at the ordinary temperature (Senderens a. Sabatier, C. R. 114, 1476 [1892]). For the reaction of $\text{Cr}_2\text{O}_3\text{Aq}$ with O and BaO_2HAq —said to give a pp. approximately BaCrO_4 —v. Péchard, C. R. 113, 89 (abstract in C. J. 60, 1431 [1891]).

Chromium salts (vol. ii. p. 167). According to Recoura (C. R. 112, 1439; abstract in C. J. 60, 1430 [1891]), the green solutions obtained by heating solutions of the normal violet chromic salts contain free acid and a soluble basic salt; in the case of the sulphate this soluble basic salt is said to be $2\text{Cr}_2\text{O}_3 \cdot 5\text{SO}_3$. For preparation of green soluble normal sulphates v. Recoura, C. R. 113, 857 (abstract in C. J. 62, 411 [1892]).

CHROM-AMMONIUM COMPOUNDS (vol. ii. p. 158). Petersen (Z. P. C. 10, 580 [1892]) finds, by cryoscopic determinations, that the formulae usually assigned to the chief salts of this class are probably molecular. For a discussion of the constitution of these salts v. Jørgensen (J. pr. [2] 42, 206; 45, 274).

CHROMATES; and derivatives (vol. ii. p. 154).

Ammonium chromates. According to Jäger a. Krüss (B. 22, 2028 [1889]), normal ammonium chromate has not hitherto been obtained pure; they prepare the pure salt by adding excess of NH_4Aq S.G. .9 to CrO_3Aq free from $\text{H}_2\text{SO}_4\text{Aq}$, warming until the solid that separates dissolves, and placing in a freezing mixture. $(\text{NH}_4)_2\text{CrO}_4$ crystallises in long, monosymmetric, golden needles, $a:b:c = 1.9603:1.24452$; S.G. 1.886 at 11° .

Ammonium trichromate $(\text{NH}_4)_2\text{Cr}_2\text{O}_7$ is prepared by J. a. K. (l.c.) by dissolving $(\text{NH}_4)_2\text{Cr}_2\text{O}_7$ in hot conc. CrO_3Aq , concentrating, and drying at 100° the red crystals that separate on cooling; S.G. 2.842 at 13° ; explodes at 190° , giving off NO , and leaving Cr_2O_3 .

Ammonium tetrachromate $(\text{NH}_4)_2\text{Cr}_4\text{O}_{13}$ is formed by dissolving the trichromate in warm HNO_3Aq S.G. 1.09, and letting cool slowly S.G. 2.843 at 10° ; melts at 170° , and suddenly decomposes at 175° , giving off NO and leaving Cr_2O_3 . J. a. K. (l.c.) failed to obtain hexachromate; they say that no nitro-chromates are obtained by treating ammonium chromates with HNO_3Aq . (For more details v. abstract in C. J. 56, 1117 [1889].) Various double compounds of

$(\text{NH}_4)_2\text{Cr}_2\text{O}_7$ with HgCl_2 are described by J. a. K. (l.c.).

Ceric dichromate $\text{CeO}_2 \cdot 2\text{CrO}_3 \cdot 2\text{H}_2\text{O}$. Prepared by passing a current of 2.5 to 8 volts through a slightly acid solution formed by dissolving $\text{Ce}_2(\text{CO}_3)_3$ in CrO_3Aq ; insoluble water, boiling water forms yellow $\text{Ce}(\text{C} \cdot \text{O})_2$ and then $\text{CeO}_2 \cdot x\text{H}_2\text{O}$ (Briouot, C. R. 118, 145 [1894]).

Lead chromates. For double compounds of PbCrO_4 with Li_2CrO_4 , K_2CrO_4 , and Na_2CrO_4 , v. Lachaud a. Lepierre, C. R. 110, 1035 (abstract in C. J. 58, 1065 [1890]).

Mercury chromates. For basic mercuric chromates and a double compound of HgCrO_4 with NH_4HgCl v. Jäger a. Krüss, B. 22, 2028 (abstract in C. J. 56, 1120 [1889]).

Potassium chromates. Jäger a. Krüss (l.c.) prepare potassium trichromate $\text{K}_2\text{Cr}_2\text{O}_7$ by treating $\text{K}_2\text{Cr}_2\text{O}_7$ with HNO_3Aq S.G. 1.19, pouring off from KNO_3 that separates, and crystallising; S.G. 2.648 at 11° . $\text{K}_2\text{Cr}_2\text{O}_7$ is quickly decomposed by water to CrO_3Aq and $\text{K}_2\text{Cr}_2\text{O}_7\text{Aq}$; melts at 250° . Potassium tetrachromate $\text{K}_2\text{Cr}_4\text{O}_{13}$ is prepared by J. a. K. (l.c.) by dissolving $\text{K}_2\text{Cr}_2\text{O}_7$ in hot conc. HNO_3Aq S.G. 1.41; S.G. 2.649 at 11° ; not deliquescent; decomposed by water; crystallises unchanged from HNO_3Aq S.G. 1.41. Schmidt (B. 25, 2917 [1893]) says that no nitrochromate is obtained by the action of HNO_3Aq on $\text{K}_2\text{Cr}_2\text{O}_7$; the substances obtained by Darmstädter (v. vol. ii. p. 158) were mixtures of KNO_3 and $\text{K}_2\text{Cr}_2\text{O}_7$.

Silver chromates. Pure silver chromate Ag_2CrO_4 is prepared by J. a. K. (l.c.) by repeatedly boiling $\text{Ag}_2\text{Cr}_2\text{O}_7$ with water as long as anything dissolves; it is a deep-green solid, insol. water.

Sodium perchromate. Häussermann (J. pr. [2] 48, 70; abstract in C. J. 64 [11], 471) describes a salt $\text{Na}_2\text{Cr}_2\text{O}_7 \cdot 28\text{aq}$, prepared by adding Na_2O_2 to a thin paste of $\text{CrO}_3\text{H}_2\text{O}$ and water, kept at 10° – 20° .

Thallium chromates. For preparation of Tl_2CrO_4 and the double compound $\text{Tl}_2\text{CrO}_4 \cdot \text{K}_2\text{CrO}_4$, v. Lachaud a. Lepierre, Bl. [3] 6, 232 (abstract in C. J. 62, 567 [1892]).

Uranium chromates. For double uranyl chromates v. Formánek, A. 257, 102 (abstract in C. J. 58, 852 [1890]).

IOCHROMATES (vol. ii. p. 157). A series of salts of the forms $\text{IO}_x \cdot \text{O} \cdot \text{CrO}_x \cdot \text{OM}^+$ and $(\text{IO}_x \cdot \text{O} \cdot \text{CrO}_x \cdot \text{O})_n \cdot \text{M}^{n+}$ has been obtained by Berg (C. R. 104, 1514 [1887]; 111, 42 [1890]); $\text{M}^+ = \text{NH}_4$, Li, K, Ag, and Na; $\text{M}^{2+} = \text{Co}$, Cu, Mg, and Ni. Most of the alkali salts were formed by dissolving the alkali iodate in excess of CrO_3Aq and crystallising; the other salts were usually prepared by dissolving the oxide or carbonate of the metal in excess of CrO_3Aq and adding HIO_3Aq . (For details v. abstracts in C. J. 52, 776 [1887]; 58, 1378 [1890].)

PHOSPHOCHROMATES. By adding conc. $\text{H}_2\text{PO}_4\text{Aq}$ + CrO_3Aq to $\text{K}_2\text{CO}_3\text{Aq}$, Blondel (C. R. 118, 194; abstract in C. J. 66 [11], 193 [1894]) obtained compounds of the form $m\text{K}_2\text{O} \cdot p\text{P}_2\text{O}_5 \cdot n\text{CrO}_3 \cdot x\text{aq}$, m being 2 and 3, n 4 and 6, and x being 0 or 1.

SULPHOCHROMATES. In 1882 Cross a. Higgin described a compound of Cr_2O_3 , SO_3 , and H_2O (C. J. 41, 113), and also compounds of Cr_2O_3 , SO_3 , K_2O , and H_2O . Recoura (C. R. 114, 477

[1892]; 116, 1367; 117, 37, 101 [1898]) has made a more complete examination of these and allied compounds. By evaporating, at 100° , solutions containing violet $\text{Cr}_2(\text{SO}_4)_3$ and H_2SO_4 , in the molecular ratio 1:1, 1:2, and 1:3, R. obtained *chromosulphuric acid* $\text{H}_2\text{Cr}_2(\text{SO}_4)_4$, *chromodisulphuric acid* $\text{H}_2\text{Cr}_2(\text{SO}_4)_5$, and *chromotrisulphuric acid* $\text{H}_2\text{Cr}_2(\text{SO}_4)_6$; by using various sulphates in place of H_2SO_4 , he obtained *chromosulphates*, *chromodisulphates*, and *chromotrisulphates*. The acids are green powders, easily sol. water; they gradually decompose in solution; dilute BaCl_2 aq. ppts. Ba chromosulphates, but conc. BaCl_2 aq. gives BaSO_4 . R. obtained *chromopyrosulphuric acid* $\text{Cr}_2(\text{OH})_2(\text{SO}_4)_2\text{H}_2$, by evaporating a solution of $\text{Cr}_2(\text{SO}_4)_3$ and H_2SO_4 , in the molecular ratio 1:5, at 100° , and heating the dark-green syrupy liquid so obtained to 110° – 115° for some days. The acid forms brittle, transparent, pale-green laminae. Salts of the form $\text{Cr}_2(\text{SO}_4)_2(\text{OM})_2$ are obtained by adding alkalis to the acid in solution; these salts R. calls *pyrosulphochromites*. By adding conc. HCl aq. or H_2SO_4 to a solution of chromopyrosulphuric acid, R. obtained a compound $\text{Cr}_2(\text{OH})_2(\text{SO}_4)_2$, *pyrosulphochromic hydroxide*, isomeric with chromosulphuric acid $\text{Cr}_2(\text{SO}_4)_2\text{H}_2$. (For more details v. abstracts in *C. J.* 62, 788 [1892]; 64 [11], 470, 528 [1893].)

COBALT (vol. ii. p. 217). Winkler has re-determined at. w. of Co, (1) by dissolving electrolytically deposited Co in HCl aq., evaporating to dryness, and determining Cl in the CoCl_2 obtained (*Zeit. f. anorg. Chemie*, 4, 10 [1893]); (2) by finding the quantity of Ag deposited from solution of Ag_2SO_4 by electrolytically deposited Co (l.c. p. 462). The values obtained were all about 59.6 ($\text{Ag} = 107.66$).

Alleged decomposition of cobalt. Krüss & Schmidt (*B. 22*, 11, 2026 [1889]) supposed they had separated Ni into two constituents (v. vol. iii. p. 500); and they thought that Co also was probably not a homogeneous substance. Remmler, in 1893, obtained a number of specimens of Co_3O_4 , by ppg. CoCl_2 aq. by KOH aq. and Br water, treating the pp. with NH_4 aq. which gradually dissolves it, decanting off the ammoniacal solution at intervals during 9 months, evaporating each and heating in CO_2 ; the different specimens of Co_3O_4 were heated in H, and the quantity of Co obtained in each case was determined. The values thus obtained for the at. w. of Co varied from 59.58 to 58.3. R. concluded that Co purified by the ordinary methods is not a homogeneous substance. Winkler's determinations of the at. w. (v. *supra*), however, gave very constant values.

Reactions.—Heated in NO to 150° , CoO is formed (Sabatier & Senderens, *C. R.* 114, 1429 [1892]); finely divided Co burns in NO_2 at the ordinary temperature, giving Co_3O_4 ; but if the NO_2 is largely diluted with N a black compound is formed, Co_3NO_4 , called by S. a. S. (*C. R.* 115, 286 [1892]) *nitro-cobalt*. This compound reacts rapidly with H_2O , giving off NO, and forming a solution containing $\text{Co}(\text{NO})_2$, with a very little $\text{Co}(\text{NO})_3$. Co remaining insoluble, and sometimes also a basic nitrite; when heated in N_2 oxides of N are given off and then rapid decomposition occurs with formation of Co and oxides of Co; when mixed with combustible substance, Co_3NO_4 ,

explodes (S. a. S., *Bl.* [3], 9, 669 [1893]). Montemartini (*G.* 22 [1], 260) finds that the gases produced by the interaction of Co and excess of HNO_3 aq. (27.5 p.c.) are NH_3 , N_2O , and N (v. abstract in *C. J.* 62, 1278 [1892]).

Cobalt, chloride of (vol. ii. p. 219). For the solubility of CoCl_2 in water, and the changes of colour produced by diluting the solution, with a discussion of the hydrations and dehydrations that accompany these changes, v. Étard, *C. R.* 113, 699 (abstract in *C. J.* 62, 278 [1892]); Engel, *Bl.* [3], 6, 239 (abstract in *C. J.* 62, 569 [1892]); and Potililtzin, *Bl.* [3], 6, 264 (abstract in *C. J.*, l.c. p. 571). The double compounds $\text{CoCl}_2 \cdot \text{HCl}$ 3aq, $\text{CoCl}_2 \cdot \text{LiCl}$ 3aq, and $\text{CoCl}_2 \cdot \text{NH}_4\text{Cl}$ 6aq are described by Chassevant (*A. Ch.* [6] 30, 5 [1893]).

Cobalt, fluoride of (vol. ii. p. 220). Poulenc (*C. R.* 114, 1426; v. abstract in *C. J.* 62, 1159 [1892]) prepares CoF_2 by heating CoCl_2 with excess of NH_4F for 15 minutes, and repeatedly washing the double fluoride $\text{CoF}_2 \cdot 2\text{NH}_4\text{F}$ thus obtained with boiling alcohol. By heating CoF_2 to 1200° – 1300° in HF, the salt is obtained in small, rose-red prisms; S.G. 4.48. The double compound $\text{CoF}_2 \cdot 2\text{KF}$ is formed by heating CoCl_2 with KHF_4 (*P.*, l.c. p. 746; abstract, l.c. p. 781).

Cobalt, iodide of (vol. ii. p. 220). For solubility in water of CoI_2 , and the formation of various hydrates attending solution, v. Étard, *C. R.* 113, 699 (abstract in *C. J.* 62, 278 [1892]).

Cobaltous oxide CoO (vol. ii. p. 220). This oxide melts in the electric furnace, and forms rose-coloured crystals (Moissan, *C. R.* 115, 1034 [1892]).

Cobaltous hydroxide $\text{CoO} \cdot \text{H}_2\text{O}$ (vol. ii. p. 220). A. de Schulten (*C. R.* 109, 266 [1889]) obtained this compound in microscopic, brownish-red, four-sided prisms, S.G. 3.597 at 15° , by heating 10 g. CoCl_2 6aq in 60 c.c. water with 250 g. KOH, in a flask filled with coal-gas, letting stand for 24 hours, and washing away the lighter amorphous products of the reaction.

Cobalto-cobaltic oxides (vol. ii. p. 221). Regarding Co_3O_4 and oxides intermediate between this and Co_2O_3 , v. Schröder, *C. C.* 1890. [1] 981 (abstract in *C. J.* 58, 1213 [1890]). Co_3O_4 , heated to c. 1750° loses all its O, and leaves Co (Read, *C. J.* 65, 313 [1894]).

Cobalt, dioxide of. By the reaction of IAq and NaOHAq on CoSO_4 aq., filtering, and acidifying with acetic acid, Vortmann (*B.* 24, 2744; abstract in *C. J.* 60, 1429 [1891]) obtained a greenish-black pp. nearly agreeing with the formula CoO . For compounds of CoO, with BaO v. Rousseau, *C. R.* 109, 64 (abstract in *C. J.* 56, 1115 [1889]).

Cobalt, salts of (vol. ii. p. 221). Marshall (*C. J.* 59, 760 [1891]) has prepared the salts $\text{Co}_2(\text{SO}_4)_3$, 18aq and $\text{Co}_2(\text{C}_2\text{O}_4)_3 \cdot 3(\text{NH}_4)_2\text{C}_2\text{O}_4$ 6aq by electrolyzing a solution of CoSO_4 in H_2SO_4 aq., and of CoC_2O_4 aq. containing $(\text{NH}_4)_2\text{C}_2\text{O}_4$.

COBALTAMMINES (vol. ii. p. 222). By cryoscopic determinations, Petersen (*Z. P. C.* 10, 580 [1892]) concludes that the formulæ generally given to the chief cobaltamines are molecular. For a discussion of the constitution of these compounds, v. Jörgensen (*J. pr.* [2] 41, 429, 440 [1890]; 42, 206; 45, 274 [1891–92]). For various octamines, v. Vortmann & Blasberg (*B.* 22, 2648), and V. a. Magdeburg (*B.* 22,

2680; *abstracts in C. J.* 58, 14 [1890]). V. a. Morgulis (*B.* 23, 2644; *abstract in C. J.* 58, 18 [1890]), describe several *mercuricobaltammines*. A number of *croceo-, luteo-, and xantho-* salts, and also several *flavo-* salts isomeric with the croceo-salts, are described by Jørgensen in *Zeit. f. anorg. Chemie*, 5, 147 (*abstract in C. J.* 65 [11], 50 [1894]).

COPPER (vol. ii. p. 251). An elaborate investigation of the at. w. of Cu has been made by Richards, *P. Am. A.* 26, 240 [1891] (*v. C. N.* 65, 236, &c.; *abstract in C. J.* 64 [11], 12 [1893]). $\text{CuSO}_4 \cdot 5\text{H}_2\text{O}$ was analysed and synthesised, and CuO was analysed; the final value obtained by R. is 63.604 ($\text{O} = 16$), or 63.44 ($\text{O} = 15.96$). The molecule of Cu in dilute solution in tin is probably monatomic (Heycock & Neville, *C. J.* 67, 876 [1890]). For the absorption spectra of solutions of CuCl_2 , CuSO_4 , and $\text{Cu(NO}_3)_2$, v. Evan, *P. M.* [5] 33, 817 (*abstract in C. J.* 64 [11], 149 [1893]).

Preparation.—For the preparation by electrolysis of pure copper v. Richards (*P. Am. A.* 25, 199, 206 [1890]).

Reactions.—Heated in the electric furnace, using a current of 70 volts and 350 amperes, Cu rapidly volatilises, and the vapour forms CuO in the air (Moissan, *C. R.* 116, 1429 [1893]). According to Neumann (*M.* 13, 40 [1893]), the H occluded in Cu, prepared by reducing CuO by H, cannot be wholly expelled by heating in a stream of CO_2 ; some of the CO_2 is also absorbed by the Cu. N. also says that Cu reduced by vapour of MeOH or EtOH, or by coal gas, retains very small traces of O and H after being heated to 220°. Montemartini (*G.* 22, 884, 397, 426 [1892]) says that the reaction between Cu and HNO_3 of less than 80 p.c. produces $\text{Cu(NO}_3)_2$ and HNO_2 , the HNO_2 then decomposing to HNO , NO, and H_2O ; with acid more conc. than 80 p.c. HNO_3 some NO_2 is produced with a little N_2O_5 , and with 70 p.c. acid only NO_2 is given off; no appreciable quantity of NH_3 is produced with acid from 3 to 27.5 p.c. HNO_3 . According to Freer & Higley (*Am.* 15, 71 [1893]), the only gaseous products of the reaction of Cu with excess of HNO_3 a.s.g. 1.4 (c. 65 p.c. HNO_3) are NO_2 and N_2O_5 , c. 90 p.c. NO_2 and 10 p.c. N_2O_5 . Cu is superficially oxidised in NO at a dull red heat (Sabatier & Senderens, *C. R.* 114, 1429 [1892]). Reduced Cu absorbs NO_2 at the ordinary temperature, forming a brownish powder Cu_2NO_2 (S. a. S., *C. R.* 115, 236 [1892]). For the reactions of this *nitro-copper* v. S. a. S., *C. R.* 116, 756 (*abstract in C. J.* 64 [11], 874 [1893]).

Copper, alloys of (vol. i. p. 253). For a description of alloys of Cu with Cd, Sn, and Zn, prepared by immersing plates of Cd, Sn, or Zn, in solutions of salts of Cu, v. Mylius & Fromm, *B.* 27, 680 (*abstract in C. J.* 66 [11], 285 [1894]).

Cupric bromide (vol. ii. p. 254). According to Sabatier (*C. R.* 118, 980 [1894]), the green crystals that separate from CuBr_2 aq are $\text{CuBr}_2 \cdot 4\text{aq}$. A solution of CuBr_2 in conc. HBr aq has an intense purple colour which becomes less marked on dilution, but even with .0015 mgm. Cu in solution the colour can be detected (C., *La.*) The *double salts* $\text{CuBr}_2 \cdot \text{CaBr}$ and $\text{CuBr}_2 \cdot 2\text{CaBr}$ are described by Wells & Walden

(*Zeit. f. anorg. Chemie*, 5, 304; *abstract in C. J.* 66 [11], 47 [1894]).

Cupric chloride (vol. ii. p. 255). Tzuchanoff (*J. R.* 25, 151; *abstract in C. J.* 66 [11], 47 [1894]) finds that the E.C. of dilute blue-coloured CuCl_2 aq increases with increase of concentration to a maximum, after which it decreases while the colour changes to yellowish-brown. For heats of solution and dilution of CuCl_2 2aq, v. Reichert & Deventer (*Z. P. C.* 5, 559 [1890]).

Double salts.— $\text{CuCl}_2 \cdot \text{HCl}$ 3aq, $\text{CuCl}_2 \cdot \text{LiCl}$ 2aq, $\text{CuCl}_2 \cdot \text{NH}_4\text{Cl}$, $\text{CuCl}_2 \cdot 2\text{NH}_4\text{Cl}$ 2aq, $\text{CuCl}_2 \cdot \text{KCl}$, and $\text{CuCl}_2 \cdot 2\text{KCl}$ 2aq (Chassevant, *A. Ch.* [6] 30, 5 [1893]); $\text{CuCl}_2 \cdot \text{CsCl}$, $\text{CuCl}_2 \cdot 2\text{CsCl}$ 2aq ($x = 0$ and 2), and $2\text{CuCl}_2 \cdot 3\text{CsCl}$ (Wells & Dupree, *Zeit. f. anorg. Chemie*, 5, 300 [1893]).

Cuprous chloride (vol. ii. p. 255). Wells (*l.c.*, p. 306) describes the *double salts* $2\text{CuCl} \cdot \text{CsCl}$, $2\text{CuCl} \cdot 3\text{CsCl}$, and $\text{CuCl} \cdot 3\text{CsCl}$ aq.

Cupric fluoride (vol. ii. p. 256). Poulenc (*C. R.* 116, 1446; *abstract in C. J.* 64 [11], 525 [1893]) prepares CuF_2 as a white amorphous powder, by heating NH_4F with CuF_2 2aq; by heating in HF at 500° (not above) the CuF_2 becomes crystalline. Crystalline CuF_2 is also obtained by heating CuO, or CuF_2 2aq, in HF at 400° (P., *l.c.*). Heated to 800° in air CuO is formed; heating in steam gives CuO and HF; H_2S forms CuS and HF; HCl forms CuCl_2 . CuF_2 absorbs water from the air, and becomes blue. H. von Helmholtz (*Zeit. f. anorg. Chemie*, 3, 115 [1892]) describes the *double salts* $\text{CuF}_2 \cdot \text{KF}$, $\text{CuF}_2 \cdot \text{RbF}$, $\text{CuF}_2 \cdot \text{AmF}$ 2aq, and $\text{CuF}_2 \cdot 2\text{AmF}$ 2aq.

Cuprous fluoride (vol. ii. p. 256). According to Mauro (*Real. Acad. Lincei*, 1892 [1], 194; *abstract in C. J.* 64 [11], 124 [1893]), Cu_2F_2 does not exist, and the substance obtained by Berzelius was almost certainly merely impure copper. Poulenc, however (*C. R.* 116, 1446; *abstract in C. J.* 64 [11], 525 [1893]), says that Cu_2F_2 is formed by heating Cu_2Cl_2 to dull redness in HF (the action is not complete until 1100°–1200°); also by heating CuF_2 in HF at c. 600°, raising the temperature to 1100°–1200° towards the end of the reaction. P. describes Cu_2F_2 that has been fused as a ruby-red, transparent solid, with a crystalline fracture; exposed to moist air it changes to CuF_2 2aq; it is easily reduced by H at a red heat.

Cuprous iodide (vol. ii. p. 256). Brun (*C. R.* 114, 667; *abstract in C. J.* 62, 1157 [1893]) describes *double compounds* with $(\text{NH}_4)_2\text{S}_2\text{O}_8$ and NH_4I , and also with $(\text{NH}_4)_2\text{S}_2\text{O}_8$ and $\text{Cu}_2\text{S}_2\text{O}_8$.

Cuprous oxide (vol. ii. p. 258). Russell (*C. N.* 68, 308 [1893]) prepares Cu_2O by completely reducing CuSO_4 aq mixed with excess of NaCl by SO_2 , heating till excess of SO_2 is removed, and then ppg. by Na_2CO_3 , added solid to the hot solution. With HFA aq, CuF_2 aq and Cu are formed (Poulenc, *C. R.* 116, 1446 [1893]).

Cupric oxide (vol. ii. p. 258). Moissan (*C. R.* 115, 1034 [1892]) says that CuO is entirely decomposed in the electric furnace at c. 2500°, yielding Cu and a crystalline compound of CuO and CaO (the reaction was effected in a block of CaO). By heating CuO to whiteness, in a Fletcher injector-furnace, in an oxidising atmosphere, Bailey & Hopkins (*C. J.* 57, 269 [1890]) obtained a very hard, yellowish-red

solid agreeing with the formula Cu_2O . Richards (*P. Am. A.* 26, 281 [1891]) found that CuO occludes gas, chiefly N; when prepared by heating $\text{Cu}(\text{NO}_3)_2$, the oxide retained c. .08 p.c. of its weight of N, which could not be removed by heating. For experiments on the dehydration of $\text{CuO} \cdot x\text{H}_2\text{O}$ v. Spring a. Lucion (*Zeit. f. anorg. Chemie*, 2, 195; *abstract in C. J.* 64 [11], 210 [1893]). For colloidal, jelly-like $\text{CuO} \cdot x\text{H}_2\text{O}$ v. J. van Bemmelen (*Zeit. f. anorg. Chemie*, 5, 466; *abstract in C. J.* 66 [11], 191 [1894]).

Copper, oxybromides of (vol. ii. p. 260). Dupont a. Jansen (*Bl.* [8] 9, 193; *abstract in C. J.* 64 [11], 463 [1893]) obtained the salt $3\text{CuO} \cdot \text{CuBr}_2 \cdot 8\text{aq}$ by heating $\text{Cu}_2\text{Br}_2\text{Aq}$ with CuO in a sealed tube at 200° , or, better, by heating neutral dilute $\text{Cu}_2\text{Br}_2\text{Aq}$ at 225° ; the compound crystallised in green rhombohedral plates, S.G. 4.39.

Copper, oxychlorides of (vol. ii. p. 260). v. Rousseau, *C. R.* 110, 1261 (*abstract in C. J.* 58, 1058 [1890]).

Copper, oxysulphides of (vol. ii. p. 260). v. Cliche, *Ar. Ph.* 228, 374 (*abstract in C. J.* 58, 1211 [1890]).

Copper, phosphides of (vol. ii. p. 260). For descriptions of Cu_3P_2 and Cu_2P , prepared by heating Cu in vapour of P, v. Granger, *C. R.* 113, 1401; and for Cu_2P_2 , prepared by heating red P with excess of Cu phosphite and water, v. G., *C. R.* 117, 281 (*abstracts in C. J.* 62, 410 [1892]; and 64 [11], 526 [1893]).

Cupric sulphide. From experiments on the interaction of H_2S and CuSO_4Aq , and CuSO_4Aq in presence of acetic acid, Linder a. Picton (*C. J.* 61, 120 [1892]) conclude that a compound $7\text{CuS} \cdot \text{H}_2\text{S}$ is formed, and that then such compounds as $9\text{CuS} \cdot \text{H}_2\text{S}$ and $22\text{CuS} \cdot \text{H}_2\text{S}$ are produced, and finally $(\text{CuS})_n$ is formed.

COPPER-AMMONIUM COMPOUNDS (vol. ii. p. 262). Several derivatives of *cupriammonium bromide* are described by Richards a. Shaw (*P. Am. A.* 28, 247 [1893]).

FERRICYANIDES.

Barium ferricyanide (vol. ii. p. 337); v. Rammelsberg, *J. pr.* [2] 39, 455 (*abstract in C. J.* 56, 950 [1889]).

Lead ferricyanide (vol. ii. p. 339); v. Rammelsberg (*loc.*).

Potassium ferricyanide (vol. ii. p. 339); v. Kassner, *Chem. Zeit.* 13, 1701 (*abstract in C. J.* 58, 352 [1890]).

DIDYMIUM (vol. ii. p. 382). For an investigation into the separation of Di and Er, v. Krüss, *A.* 265, 1 (*abstract in C. J.* 60, 1424 [1891]). For the emission spectra of oxides of neodymium and praseodymium, v. Haitinger, *M.* 12, 362 (*abstract in C. J.* 62, 2 [1892]). Read (*C. J.* 65, 313 [1894]) says that Di_2O_3 is unchanged at c. 1750° .

ERBIUM (vol. ii. p. 456). For the separation of compounds of Er and Di, v. Krüss, *A.* 265, 1 (*abstract in C. J.* 60, 1424 [1891]).

FERRITES (vol. ii. p. 547). J. van Bemmelen a. Klobbie (*J. pr.* [2] 43, 497 [1893]) say that $\text{Fe}_2\text{O}_3 \cdot \text{K}_2\text{O}$ and $\text{Fe}_2\text{O}_3 \cdot \text{Na}_2\text{O}$ are obtained, in crystals, by continued heating Fe_2O_3 with conc. KOHaq and NaOHaq respectively; these

ferrites are decomposed by water, giving $\text{Fe}_2\text{O}_3 \cdot \text{H}_2\text{O}$.

FLAME (vol. ii. p. 549). References should be made to Smithells a. Ingle on 'The Structure and Chemistry of Flames' in *C. J.* 61, 204 [1892], and to Lewes on 'The Luminosity of Coal-gas Flames' in *ibid.* p. 322.

FLUORHYDROIC ACID (vol. ii. p. 558). Berthelot a. Moissan (*C. R.* 109, 209 [1889]) give the thermal data $[\text{H}, \text{F}] = 37,600$; $[\text{H}, \text{F}, \text{Aq}] = 49,400$. For the description of an apparatus for purifying HFAq , v. Hamilton (*C. N.* 60, 252 [1889]).

FLUORINE (vol. ii. p. 560). Moissan (*C. R.* 111, 570 [1890]) determined the at. w. (1) by converting Na_2CO_3 into NaF , and this into Na_2SO_4 ; (2) by converting CaF_2 into CaSO_4 , and (3) by converting BaF_2 into BaSO_4 ; the mean of the results regarded by M. as the most trustworthy was 19.05. V.D. at the ordinary temperature, 18.8 (Moissan, *C. R.* 109, 861; v. *abstract in C. J.* 58, 203 [1890]). A column of F one metre long shows no definite absorption bands (M., *loc.* p. 937); for the emission spectrum v. M. (*loc.*; *abstract in C. J.* 58, 329 [1890]). F does not liquefy at -95° at the ordinary pressure (M., *A. Ch.* [6] 25, 125 [1893]). Gladstone (*P. M.* [5] 81, 1 [1891]) has determined the atomic refraction of F in $\text{C}_2\text{H}_5\text{F}$ to be as follows for the different lines of the solar spectrum, at 22.8° :—

	A	C	D	F	G	H
at. refraction	.63	.63	.53	.48	.44	.35

The values are much smaller than those for Cl, Br, or I, which are 10.0, 15.23, and 25.2 for the line A.

Formation.—According to Brauner (*C. J.* 65, 393 [1894]), F is given off when $3\text{KF} \cdot \text{PbF}_2 \cdot \text{HF}$ (v. LEAD TETRAFLUORIDE, p. 915) is heated to dull redness.

Reactions.—F combines with the more porous forms of carbon at the ordinary temperature, with incandescence, forming CF_4 ; the denser forms of C combine with incandescence at from 50° to 100° (Moissan, *C. R.* 110, 276; *abstract in C. J.* 58, 557 [1890]). For a discussion of the chemical relations of F, v. Moissan, *Bl.* [8] 5, 880 [1891].

GALLIUM (vol. ii. p. 597). Leococq de Boisbaudran (*C. R.* 114, 815; *abstract in C. J.* 62, 930 [1892]) gives measurements of the chief lines in the spark emission spectrum of Ga; the spectrum varies much according to the conditions under which the spark is applied.

GERMANIUM (vol. ii. p. 610). A new mineral from Bolivia, *canfieldite*, Ag_3GeS_3 , identical in composition with *argyrodite* from Freiberg, but crystallising in isometric forms (the form of *argyrodite* is monoclinic), is described by Penfield in *Am. S.* [3] 46, 107 (*abstract in C. J.* 66 [11], 18 [1894]).

GOLD (vol. ii. p. 647). Mallet (*Pr.* 46, 71; *abstract in C. J.* 58, 708 [1890]) has re-determined the at. w. of gold by various methods; the mean value obtained is 196.9, but the value 196.88 M. thinks is more trustworthy. The molecule of gold in dilute solution in tin is probably monatomic (Heycock a. Neville, *C. J.* 57, 376 [1890]). Gold volatilises considerably in the electric furnace with a current of 70 volts and 360 ampères (Moissan, *C. R.* 116, 1429 [1893]).

Concerning the volatilisation of gold *v.* Rose (*C. J.* 63, 714 [1893]). Neumann (*M.* 18, 40 [1892]) says that gold absorbs from 33 to 48.5 times its volume of O at c. 450°. According to Petersen (*Z. P. C.* 8, 601 [1891]), the heats of formation of $\text{Au}_2\text{O}_3 \cdot 8\text{H}_2\text{O}$ from gold, (1) reduced from AuCl_3 , (2) from AuHBr_3 , and (3) from AuBr , differ very markedly. From the results of many experiments on the reaction between gold and KONaAq , Maclaurin (*C. J.* 63, 724 [1893]) concludes that O must be present to accomplish solution, and that the equation $4\text{Au} + 8\text{KONaAq} + \text{O}_2 + 2\text{H}_2\text{O} = 4(\text{AuCN.KCN})\text{Aq} + 4\text{KOH}\text{Aq}$ (Elsner, *J. pr.* 87, 333 [1846]) expresses the proportion between K and Au in the solution.

Gold, alloys of (vol. ii. p. 648). For an alloy with Cd, AuCd , *v.* Heycock & Neville (*C. J.* 61, 914 [1892]). For alloys with Cd and Sn, *v.* H. a. N. (*C. J.* 59, 936 [1891]). For alloys with Al and Sn, Cd and Bi, Cd and Pb, and Cd and Tl, *v.* H. a. N. (*C. J.* 65, 65 [1894]). For alloys with Cd and with Zn, prepared by immersing plates of Cd and Zn in solution of a salt of gold, *v.* Mylius & Fromm (*B.* 27, 630; *abstract in C. J.* 66 [11], 235 [1894]).

Gold, bromides of (vol. ii. p. 648). Petersen (*J. pr.* [2] 46, 328) upholds the existence of Au_2Br , against the statements of Krüss & Schmidt (*B.* 20, 2634); in a later paper (*J. pr.* [2] 47, 301) K. a. S. still maintain that AuBr is the ultimate product of the reaction of Br with gold (*v. abstracts in C. J.* 64 [11], 126, 284). For the double salts $\text{AuBr}_3 \cdot \text{CsBr}$ and $\text{AuBr}_3 \cdot \text{RbBr}$, *v.* Wells & Wheeler (*Am. S.* [3] 44, 157 [1892]).

Gold, chlorides of (vol. ii. p. 649). Petersen (*J. pr.* [2] 46, 328; 48, 88) maintains that Au_2Cl_3 is a definite compound; Krüss & Schmidt (*J. pr.* [2] 47, 301; *Zeit. f. anorg. Chemie*, 3 421) say this substance is a mixture (*v. abstracts in C. J.* 64 [11], 126, 284, 474 [1893]).

Double salts of AuCl_3 with CsCl and RbCl are described by Wells & Wheeler (*l.c.*); for a double salt $\text{AuCl}_3 \cdot \text{AgCl}$, *v.* Hermann (*B.* 27, 596; *abstract in C. J.* 66 [11], 234 [1894]).

Gold, sulphides of (vol. ii. p. 651). Concerning the conditions of formation of Au_2S_3 , *v.* Antony & Lucchesi (*G.* 19, 545; *abstract in C. J.* 58, 1216 [1890]).

Auric sulphide Au_2S_3 . This compound is formed, according to A. a. L. (*G.* 20, 601; 21 [11], 209; *abstracts in C. J.* 60, 526; 62, 280 [1892]), by passing H_2S into a solution of $\text{AuCl}_3 \cdot \text{LiCl}$ kept at -10° , extracting LiCl by absolute alcohol, and drying in N at 70° . Au_2S_3 is a black, amorphous solid; decomposed by heat at 200° – 205° to Au and S (for other reactions *v. abstracts, l.c.*).

Schneider (*U. S. Geol. Survey Bull.* No. 90, 66 [1892]) obtained aqueous solutions of colloidal Au_2S_3 and Au_2S_2 .

HYDRAZOIC ACID (*v.* p. 919, *Addenda*).

HYDROGEN (vol. ii. p. 719). The ratio between the densities of H and O is 1:15.882, the weight in grams of 1 litre of H is .08991 (Rayleigh, *Pr.* 53, 134 [1893]). For solubility in water, and in alcohol, *v.* Timoféeff (*Z. P. C.* 6, 141); Winkler (*B.* 24, 89); Henrich (*Z. P. C.* 9, 435; (*abstracts in C. J.* 60, 15, 884 [1891]; 62, 1043 [1892]). For the line spectrum of H, *v.*

Ames (*P. M.* [5] 30, 48 [1890]); and *cf.* Grünwald (*M.* 18, 111; *abstract in C. J.* 62, 1331 [1892]).

Wilm (*B.* 25, 217; *abstract in C. J.* 62, 568 [1892]) describes a lecture experiment to show the occlusion of H by Pd. Regarding the occlusion of H by other metals *v.* Streintz (*M.* 12, 642; *abstract in C. J.* 62, 567 [1892]).

Baker (*C. J.* 65, 611 [1894]) found that a mixture of equal volumes of dry H and dry Cl did not explode in bright sunlight, and that more than a quarter of the mixed gases remained uncombined after exposure for two days to diffused light and two days to bright sunshine.

Reactions.—Neumann (*Z. P. C.* 14, 193 [1894]) has examined the reducing action of H occluded by Pt on solutions of salts of Al, Sb, As, Bi, Cd, Cu, Co, Au, Fe, Pb, Mg, Mn, Hg, Ni, Pd, Ag, Sn, Tl, and Zn. Regarding the rate of combination of H and O, *v.* WATER (p. 860). Regarding the explosion of mixtures of H with O and Cl, *v.* CHLORINE (*Addenda*, pp. 904, 905).

Hydrogen dioxide (vol. ii. p. 722). Schöné (*B.* 26, 3011; 27, 1233 [1893–4]) affirms the occurrence of L_2O_2 in the atmosphere against the contention of Illosva (*B.* 27, 920).

Formation.—Regarding the formation from ether *v.* Dunstan & Dymond (*C. J.* 57, 574, 988 [1890]). $\text{H}_2\text{O}_2\text{Aq}$ is formed by the action of light on $\text{H}_2\text{C}_2\text{O}_4\text{Aq}$, excess of O being present (Richardson, *C. J.* 65, 450 [1894]). Richardson (*C. J.* 63, 1110 [1893]) has examined the formation of H_2O_2 in urine exposed to sunlight.

Preparation.—By making commercial 3 p.c. $\text{H}_2\text{O}_2\text{Aq}$ distinctly alkaline by Na_2CO_3 , filtering, shaking with 10–12 vols. of ether, separating the ethereal solution, evaporating this to .01–.0025 of its original volume on a water-bath, and removing the rest of the ether by standing in a bell-jar over solid paraffin, Shiloff (*J. R.* 25, 293; *abstract in C. J.* 66 [11], 186 [1894]) obtained a thick, transparent, slightly acid liquid, S.G. 1.2475, containing 79.6 g. H_2O_2 in 100 c.c. For preparation of conc. $\text{H}_2\text{O}_2\text{Aq}$ *v.* Talbot & Moody (*abstract in C. J.* 64 [11], 369 [1893]).

Molecular weight. Tammann in 1893 (*Z. P. C.* 4, 441) by cryoscopic measurements determined mol. formula to be H_2O_4 ; but T.'s results were called in question by Carrara in 1893 (*G.* 22 [1], 841), who found mol. w. 33.92 (H_2O_2) from cryoscopic measurements, and this result was confirmed by Orndorff & White (*Am.* 15, 347 [1893]), and also by Tammann himself (*Z. P. C.* 12, 431 [1893]).

Reactions.—Regarding the reaction between $\text{H}_2\text{O}_2\text{Aq}$ and KMnO_4Aq , *v.* Engel (*Bl.* [3] 6, 17; *abstract in C. J.* 62, 277 [1892]).

Hydrogen sulphide (vol. ii. p. 725). Henrich (*Z. P. C.* 9, 435 [1892]) gives the absorption coefficient of H_2S by water as 4.4015–.0891177 + .00061954*t*. Hughes (*P. M.* [5] 33, 471 [1892]) says that H_2S dried by CaCl_2 and P_2O_5 does not redden dry litmus paper, and does not react with BaO or Fe_2O_3 , nor with salts of Sb, As, Bi, Cd, Co, Cu, Pb, Hg, Ag, or Sn. According to Pedler (*C. J.* 57, 625 [1890]), the equation $2\text{H}_2\text{S} + 3\text{O}_2 = 2\text{SC}_2 + 2\text{H}_2\text{O}$ correctly represents the explosion of H_2S and air or O.

HYDROXYLAMINE (vol. ii. p. 754). NH_2OH has been isolated, as a solid, by Kobry de Bozyn

(*R. T. C.* 10, 100; 11, 18; *abstracts in C. J.* 62, 402, 1891 [1892]). $\text{NH}_4\text{OH} \cdot \text{HCl}$ dissolved in MeOH is treated with CH_3ONa solution, and most of the MeOH is distilled off at 100 mm. pressure; the residue is distilled in small portions at 40 mm. pressure (for details *v. C. J., l.c.*). For the preparation from $2\text{NH}_4\text{OH} \cdot \text{ZnCl}_2$ *v. Crismer, Bl. [8] 6, 798 (abstract in C. J. 62, 771 [1892])*. For details of suitable apparatus for the fractionation of NH_4OH *in vacuo*, *v. Brühl (B. 26, 2508 [1893]; cf. L. de B., B. 27, 967; and reply by B., ibid., 1847 [1894])*. For thermal data of NH_4OH , *v. Berthelot a. André (C. R. 110, 830; abstract in C. J. 58, 934 [1890])*. Hydroxylamine is a white inodorous solid, melting at $c. 33^\circ$, and remaining superfused at 0° ; boils at 58° under 22 mm. pressure; decomposes at 90° – 100° , and detonates at a higher temperature. S.G. 1.35; S.G. when liquid, 1.23. A drop heated in a test tube explodes very violently (*v. Brühl, l.c.*). *B., l.c.*, discusses the molecular refraction of NH_4OH . NH_4OH is fairly stable up to 15° , then gradual decomposition occurs, giving NH_3 , HNO_2 , and $\text{H}_2\text{N}_2\text{O}_2$, which react with unchanged NH_4OH producing N_2O and N (*L. de B., B. 27, 967; abstract in C. J. 66 [11], 278 [1894]*). For a full account of the reactions of NH_4OH *v. Lobry de Bruyn (l.c.; abstract in C. J. 62, 1391 [1892])*. $\text{NH}_4\text{OH} \cdot \text{HCl}$ in water and NaNO_3 *Aq* react to form $\text{Na}_2\text{N}_2\text{O}_5$ *Aq* (*v. Tanatar, J. R. 25, 342; abstract in C. J. 66 [11], 136 [1894]; cf. Wislicenus, B. 26, 771; abstract in C. J. 64, 318 [1892]*). For the reactions of $2\text{NH}_4\text{OH} \cdot \text{H}_2\text{SO}_4$ with NaOHAq *v. Kolotoff (J. R. 25, 295; abstract in C. J. 66 [11], 187 [1894])*. For compounds of NH_4OH with metallic salts, *v. Crismer (Bl. [8] 8, 114; Goldschmidt a. Syngros (Zeit. f. anorg. Chemie, 5, 129); and Feldt (B. 27, 401) (abstracts in C. J. 58, 558 [1890]; 66 [11], 45, 187 [1894])*. Kolotoff discusses the constitution of NH_4OH in *J. R. 23, 3 (abstract in C. J. 64 [11], 114 [1893])*. Kjellin (*B. 26, 2377*) describes NH_4EtOH and NHMeOH (*abstract in C. J. 66 [11], 9 [1894]*).

INDIUM (vol. iii. p. 1). The molecule of indium in dilute solution in tin is perhaps diatomic (*v. Heycock a. Neville, C. J. 57, 376 [1890]*). Linder a. Picton (*C. J. 61, 134 [1892]*) failed to isolate indium hydrosulphide, but they think that it is formed by passing H_2S into water with $\text{In}_2\text{O}_3 \cdot x\text{H}_2\text{O}$ in suspension; the continued passage of H_2S produces In_2S_3 . Read (*C. J. 65, 313 [1894]*) found that indium sesquioxide, In_2O_3 , is unchanged at $c. 1750^\circ$.

IODHYDRIC ACID (vol. iii. p. 11). For the Mol. R. of HIAq from 20.77 to 67.02 p.c., *v. Perkin (C. J. 55, 708 [1889])*. For a research on the dissociation of HI , *v. Bodenstein (Z. P. C. 13, 56 [1894]; abstracts in C. J. 64 [11], 369; 66 [11], 12 [1893–4])*. Pickering (*B. 26, 2307*) has isolated three hydrates of HI : $\text{HI} \cdot 2\text{H}_2\text{O}$, melting at -43° ; $\text{HI} \cdot 3\text{H}_2\text{O}$, melting at $c. -46^\circ$; and $\text{HI} \cdot 4\text{H}_2\text{O}$, melting at $c. -36.5^\circ$.

IODINE (vol. iii. p. 14). The mol. w. of iodine dissolved in Et_2O or CS_2 was found by Beckmann (*Z. P. C. 5, 76 [1890]*) to be 254, from determinations of the boiling points; these results were confirmed by Sakurai (*C. J. 61, 397 [1892]*). By determining the lowering of the *m.p.* of naphthalene by solution therein of I ,

Hertz (*Z. P. C. 6, 358 [1890]*) found the value 254 for the mol. w. of iodine.

According to Meineke (*Chem. Zeitung*, 16, 1219, 1230), very pure I is prepared by covering ordinary I with a solution of CaCl_2 , S.G. 1.35, mixed with a little conc. KIAq and a few drops of HClAq , heating until the I fuses, letting cool, washing the I , drying, and subliming it twice, the first time with addition of a little BaO .

For the reactions of I with KClO_3 , and with KClO_4 and water, *v. POTASSIUM CHLORATE (Addenda, p. 905)*.

Iodine monochloride (vol. iii. p. 17). For thermal data bearing on the two forms of ICl , *v. Stortenbeker (Z. P. C. 10, 183; abstract in C. J. 62, 1387 [1892])*. Tanatar (*J. R. 25, 97; abstract in C. J. 64 [11], 514*) gives details of the methods for preparing the two forms of ICl .

Iodates (vol. iii. p. 21). For *iodates of cesium and rubidium*, *v. Wheeler, Am. S. [8] 44, 123 (abstract in C. J. 64 [11], 68 [1894])*. Pure *potassium iodate* is prepared, according to Gröger (*Zeit. angew. Chemie*, 1894, 13), by heating to 100° for 20–30 minutes 20 g. KI in as little water as possible mixed with 40 g. pure KMnO_4 , in 1,000 c.c. water, reducing excess of KMnO_4 by cautious addition of alcohol, filtering, adding acetic acid till acid, evaporating to $c. 50$ c.c., washing the crystals of KIO_3 with conc. alcohol, and drying. By heating KIO_3 till it fuses, O and some I are given off, and KI finally remains; no other oxy-compounds are formed (Cook, *C. J. 65, 802 [1894]*).

IRIDIUM (vol. iii. p. 46). From analyses of the salts $\text{ICl}_3 \cdot 3\text{KCl}$ *Aq* and $\text{ICl}_3 \cdot 3\text{NH}_4\text{Cl}$ *Aq*, Joly deduced the value 192.75 for the at. w. of Ir (*C. R. 110, 1131 [1890]*). According to Prinz (*C. R. 116, 892 [1893]*), Ir crystallises in regular octahedra and in forms derived therefrom. Mylius a. Foerster (*B. 25, 665 [1892]*) stated that Ir is slightly volatilised when heated in a current of CO and Cl to $c. 238^\circ$; Antony, however (*G. 22 [11], 547 [1893]*), asserts that no trace of any volatile compound of Ir is formed under these conditions.

Irid-ammonium salts (vol. iii. p. 47). Palmaer (*B. 22, 15; 23, 3810 [1889–90]*) describes a number of *irido-ammonium compounds*. He calls them *iridiumpentammine salts*, and formulates them as $\text{Ir}(\text{NH}_3)_5\text{X}_2$; compounds are described where $\text{X}_2 = \text{Cl}_2$, ClBr , ClI , ClSO_3 , $\text{Cl}(\text{NO}_2)$, $\text{Cl}(\text{NO}_2)_2$, ClC_2O_4 , ClPbCl_2 ; also where $\text{X}_2 = \text{Br}_2$, BrSO_3 , and $\text{Br}(\text{NO}_2)_2$. One-third of the Cl in the salt when $\text{X}_2 = \text{Cl}_2$ is not removed by the action of cold H_2SO_4 *Aq* or cold AgNO_3 *Aq*; the reactions of the salts are similar to those of the purpureo-cobaltamines (*v. vol. ii. p. 227 (v. abstracts in C. J. 56, 352 [1889]; 60, 402 [1891])*). In *B. 24, 2090 (v. abstract in C. J. 60, 1165 [1891])* P. describes compounds analogous with the roseo-cobaltic salts $\text{Co}_2(\text{NH}_3)_6(\text{H}_2\text{O})_2\text{X}^n$ *Aq*; as the Ir salts are almost colourless, P. thinks the prefix *roseo-* is unsuitable; he calls them *iridium aquopentamines*, and formulates them as $\text{Ir}(\text{NH}_3)_5(\text{H}_2\text{O})\text{X}_2$. Salts are described in which $\text{X}_2 = \text{Br}_2$, Cl_2 , and $(\text{NO}_2)_2$. The *chloride* $\text{Ir}(\text{NH}_3)_5(\text{H}_2\text{O})\text{Cl}_2$ is formed by boiling, for five hours, 6 g. $\text{Ir}(\text{NH}_3)_6\text{Cl}_3$ with $1\frac{1}{2}$ times the calculated weight of KOH in 50 c.c. water, filtering, partially freezing the filtrate, adding 50 c.c. fuming HClAq , washing the pp. thus formed

with 22 p.c. cold HClAq and then with alcohol, dissolving in water, and again ppg. by conc. HClAq (for details *v. abstract* in *C. J.* 60, 1166 [1891]).

Iridium tribromide (vol. iii. p. 48). Compounds of this bromide with PBr₃ are described by Geisenheimer (*C. R.* 111, 40; *abstract* in *C. J.* 58, 1838 [1890]). By heating IrO₃.xH₂O with IrBr₃ and PBr₃, red needles of IrBr₃.3PBr₃ are formed; by heating this with PBr₃, black crystals of IrBr₃.2PBr₃ are produced.

Iridium tetrabromide (vol. iii. p. 48). Geisenheimer (*l.c.*) describes the compound IrBr₃.2PCl₅, obtained by heating IrBr₃.3PBr₃ with PCl₅.

Iridium trichloride (vol. iii. p. 48). The following compounds with PCl₅ are described by Geisenheimer (*C. R.* 110, 1004; *abstract* in *C. J.* 58, 1068 [1890]). IrCl₃.3PCl₅; IrCl₃.2PCl₅; IrCl₃.PCl₅.2PCl₅; IrCl₃.PCl₅.PCl₅. Various compounds of IrCl₃ with H₃PO₄ and H₂PO₃, and salts of these, are also described. G. (*C. R.* 110, 1836; *abstract* in *C. J.* 58, 1069 [1890]) also describes the complex compounds 2IrP₂Cl₅.5AsCl₃ and IrCl₃.2PCl₅.2AsCl₃. For the salts IrCl₃.3KCl. aq and IrCl₃.3AmCl. aq. *v. Joly* (*C. R.* 110, 1181; *abstract* in *C. J.* 58, 1067 [1890]). For a description of IrCl₃.3LiCl. 2aq. *v. Antony* (*G.* 23 [1], 190; *abstract* in *C. J.* 64 [11], 380 [1893]). According to A. (*G.* 23 [1], 184; *abstract* in *C. J.* 64 [11], 379 [1890]), the passage of H₂S through a 2 p.c. solution of IrCl₃.3KCl produces pps. which are mixtures of Ir₂S₃ and IrS₂.

Iridium dioxide (vol. iii. p. 50). For methods of preparing IrO₂, *v. Geisenheimer* (*C. R.* 110, 855; *abstract* in *C. J.* 58, 948 [1890]).

Iridium disulphide (vol. iii. p. 50). IrS₂ is obtained by passing H₂S over IrCl₃.3LiCl at 4° to 7°, washing with absolute alcohol, and drying at 90° to 100° in a current of CO₂ (Antony, *G.* 23 [1], 190; *abstract* in *C. J.* 64 [11], 380 [1893]).

IRON (vol. iii. p. 51). Lockyer (*Pr.* 54, 359 [1893]) gives the emission spectrum obtained by using very fine electrolytically deposited iron as the poles of an electric lamp.

Properties and Reactions.—Iron volatilises in the electric furnace, using a current of 350 amperes and 50 volts (Moissan, *C. R.* 116, 1429 [1893]). Iron is superficially oxidised by heating to dull redness in NO (Sabatier & Senderens, *C. R.* 114, 1429 [1892]); heated in NO₂ to c. 350°, reduced iron is oxidised with incandescence to Fe₂O₃ (S. a. S., *C. R.* 115, 236 [1892]; *cf. abstract* in *C. J.* 66 [11], 95 [1894]). Montemartini (*G.* 22 [1], 250) says that NH₃, N₂O, and N are formed by the solution of iron in excess of 27.5 p.c. HNO₃Aq (for quantities, *v. abstract* in *C. J.* 62, 1278 [1892]). For quantities of iron dissolved by HNO₃Aq of different concentrations, *v. Gautier & Charpy* (*C. R.* 112, 1451; *abstract* in *C. J.* 60, 1426 [1891]).

Passivity of iron. Concerning the passivities of steel and wrought iron to HNO₃Aq, *v. Andrews* (*Pr.* 48, 116; 49, 481; *abstracts* in *C. J.* 60, 250, and 64 [11], 16 [1891 and 1893]).

Iron, bromochloride of. The compound FeBrCl₂ was obtained by Lenormand (*C. R.* 116, 820; *abstract* in *C. J.* 64 [11], 377) by heating FeCl₃ with excess of Br in a sealed tube at c. 100°. The compound is opaque in thin

sections, and green by reflected light; very deliquescent; crystallises probably in hexagonal plates; easily sol. alcohol and ether, CS₂, &c., can be sublimed by heating in a tube containing a little Br.

Iron carbide. Arnold & Read (*C. J.* 65, 788 [1894]) confirm the existence of Fe₃C in steel (*v. Abel*, *Proc. Inst. Mechan. Engineers*, 1885, 30; also Müller, *Stahl und Eisen*, No. 5); A. a. R. say that two forms of Fe₃C are found in steel.

Iron carbonyls. In 1891 Mond & Quincke (*C. J.* 59, 604) obtained a compound of Fe with CO; further investigation of the reaction by Mond & Langer (*C. J.* 59, 1090 [1891]) led to the isolation of two compounds.

Ferropentacarbonyl Fe(CO)₅. Mol. w. 195.55. V.D. at 142° = 93.2, S.G. $\frac{18^\circ}{15^\circ} = 1.4664$; distils completely, without decomposition, at 102.8° under 749 mm. pressure; solidifies at -21°.

Preparation.—FeC₂O₄, ppd. by adding a slight excess of K₂C₂O₄Aq to hot FeSO₄Aq, is well washed, and dried at 120°; it is then heated in a slow stream of H, temperature being raised until the substance in the tube is black, and then kept constant until gas ceases to come off, when the current of H is stopped; the product is allowed to cool in H, placed in water without coming into the air, and treated with successive quantities of boiling water until sulphate is removed; it is then quickly dried on plates of gypsum, placed in the combustion tube, heated to c. 300° in H till quite dry, and allowed to cool in H. The tube is then connected with a gas-holder containing CO, and the H is completely displaced by CO; one end of the tube is then sealed, and the open end is kept in connection with the supply of CO. After 24 hours the tube is heated to c. 120°, while a slow current of CO is passed through it, and the issuing gases are passed through a tube kept at -20°. When iron carbonyl ceases to come over, the tube is let cool, and is then again put in connection with the CO supply. These processes are repeated many times; the daily yield of the carbonyl is not more than c. 1 g. from 100 g. iron.

Properties.—A pale-yellow, somewhat viscous liquid; unchanged in the dark, but in sunlight gives solid Fe₂(CO)₉ (*v. infra*); slowly decomposed on exposure to air, giving chiefly Fe₂O₃.xH₂O; completely decomposed at 180° to Fe and CO; soluble in EtOH, Et₂O, C₂H₅, mineral oils, &c. (For S.G., V.D., &c., *v. supra*). Fe(CO)₅ is not acted on by dilute H₂SO₄Aq, HClAq, or HNO₃Aq at the ordinary temperature; but is rapidly decomposed—to Fe(NO₃)₃Aq, FeCl₃Aq, or FeBr₃Aq—by conc. HNO₃Aq, ClAq, or BrAq.

Diferroheptacarbonyl Fe₂(CO)₉. Obtained by exposing Fe(CO)₅ in a sealed tube to sunlight for some hours, collecting the solid that forms, washing with ether, and drying over H₂SO₄ for a short time. Yellow, lustrous flakes; gradually decomposed by exposure to air, turning brown. Not acted on by H₂SO₄Aq or HClAq at the ordinary temperature; decomposed by HNO₃Aq, Cl, or Br.

Iron carbonyls seem to be present in *vgter-*

gas; also sometimes in compressed coal-gas (v. Roscoe a. Scudder, *C. J. Proc.* 1891. No. 101).

Ferrous chloride (vol. iii. p. 53). Chassevant (*A. Ch.* [6] 30, 5 [1893]) describes the double salts $\text{FeCl}_2 \cdot 2\text{AmCl}$, $\text{FeCl}_2 \cdot \text{LiCl}$, 3aq , and $\text{FeCl}_2 \cdot 2\text{KCl}$.

Ferric chloride (vol. iii. p. 54). By determining the ρ of b.p. of alcohol and ether when FeCl_3 is dissolved in these solvents, Müller (*C. R.* 118, 644; abstract in *C. J.* 66 [11], 282 [1894]), finds that the molecular formula of the chloride in these solutions is FeCl_3 . FeCl_3Aq reacts with many metallic sulphides, when heated therewith in sealed tubes; FeCl_3Aq , S, and a chloride of the metal of the sulphide are generally formed (Cammerer, *C. C.* 1891 [11], 370; abstract in *C. J.* 62, 18 [1892]). Seubert a. Dorner (*Zeit. f. anorg. Chemie*, 5, 339, 411; v. abstracts in *C. J.* 66 [11], 140, 190 [1894]) have made a full investigation of the interaction of FeCl_3Aq and KIAq ; their results are in keeping with the hypothesis that the direct reaction $\text{FeCl}_3\text{Aq} + \text{KIAq} = \text{FeCl}_2\text{Aq} + \text{KClAq} + \text{IAq}$ is counterbalanced by the reverse reaction $\text{FeCl}_2\text{Aq} + \text{KClAq} + \text{IAq} = \text{FeCl}_3\text{Aq} + \text{KIAq}$. S. a. D. think that the first stage of the reaction is to produce an iodochloride; thus $\text{FeCl}_3\text{Aq} + \text{KIAq} = \text{FeCl}_2\text{Aq} + \text{KClAq}$; that this then decomposes, more or less completely (according to conditions of concentration, time, temperature, and mass), into FeCl_2Aq and IAq ; and that FeCl_2Aq , and probably FeCl_3Aq , are re-formed until equilibrium is established. S. a. D. do not agree with the explanation of the mechanism of the reaction given by Carnegie (v. vol. iii. p. 55). Roozeboom (*Z. P. C.* 10, 477 [1892]) has investigated the conditions of equilibrium in aqueous solution of the hydrates of FeCl_3 ; he has isolated hydrates $2\text{FeCl}_3 \cdot x\text{H}_2\text{O}$ where $x = 4, 5, 7$, and 12. (For details, v. abstract in *C. J.* 64 [11], 119 [1893]). For a study of the interaction of FeCl_3Aq and oxalic acid, v. Lemoine, *C. R.* 116, 961 (abstract in *C. J.* 64 [11], 405 [1893]). A compound of FeCl_3 with nitrosyl chloride, $\text{FeCl}_3 \cdot \text{NOCl}$, was obtained by Sudborough (*C. J.* 59, 660 [1891]), by immersing iron in liquid NOCl , and letting the liquid stand over H_2SO_4 ; the compound forms small golden-brown, deliquescent crystals (cf. vol. iii. p. 56; *Combinations*, No. 7).

Ferrous fluoride (vol. iii. p. 56). FeF_2 was obtained by Poulenc (*C. R.* 115, 941; abstract in *C. J.* 64 [11], 122 [1893]) by passing air-free HF over red-hot iron or dry FeCl_3 ; small, white, rhombic prisms; S.G. 4.09; decomposed by heating with H_2SO_4 , Na_2CO_3 , steam, air, HCl , or H.

Ferric fluoride (vol. iii. p. 56). Poulenc (*l.c.*) obtained FeF_3 , in small, very refractive, greenish crystals, S.G. 3.87, by passing HF over red-hot iron, Fe_2O_3 , FeF_2 , 3aq , or FeCl_3 ; also by dropping FeF_3 , 3aq into fused AmCl and heating in a current of an inert gas. FeF_3 does not fuse at 1000° ; but is decomposed by heating in air, also by fusion with Na_2CO_3 , by heating in steam, or with HCl or H_2SO_4 . According to Speransky (*J. R.* 24, 304; abstract in *C. J.* 64 [11], 314 [1893]), FeF_3Aq shows a very small electrical conductivity; there is, therefore, no appreciable electrolytic dissociation; as the solution scarcely affects any inversion of cane sugar, S. concludes

Vol. IV.

that there is practically no hydrolytic dissociation. Cryoscopic determinations showed that the molecules in a dilute aqueous solution are chiefly FeF_3 , but indicated the existence of Fe_2F_7 , in more conc. solutions.

Iron, nitrides of (vol. iii. p. 59). Fowler (*C. N.* 68, 152 [1893]) obtained Fe_3N by heating reduced iron in a rapid stream of NH_3 . (For details v. abstract in *C. J.* 66 [11], 50 [1894].)

Ferric oxide (vol. iii. p. 61; also p. 57 for hydrates). At $c. 1750^\circ$ Fe_2O_3 is completely changed to Fe_3O_4 (Read, *C. J.* 65, 313 [1894]); in the electric furnace Fe_3O_4 is formed, partly melted and partly crystallised (Moissan, *C. R.* 115, 1034 [1892]). According to J. van Bemmelen a. Klobbie (*J. pr.* [2] 46, 497 [1893]), crystallised $\text{Fe}_2\text{O}_3 \cdot \text{H}_2\text{O}$ is obtained by treating with water the hexagonal crystals of $\text{Fe}_2\text{O}_3 \cdot \text{Na}_2\text{O}$ formed by heating Fe_2O_3 for some time with conc. NaOHaq ; the crystalline $\text{Fe}_2\text{O}_3 \cdot \text{H}_2\text{O}$ is not hygroscopic; H_2O is given off below 100° .

Iron, oxychlorides of (vol. iii. p. 62). Rousseau (*C. R.* 110, 1032; 113, 643; 116, 392; abstracts in *C. J.* 58, 1063 [1890]; 62, 119 [1892]; 64 [11] 280 [1893]) describes compounds $x\text{FeCl}_2 \cdot y\text{Fe}_2\text{O}_3$, some crystalline and some amorphous, formed by heating FeCl_3Aq at different temperatures, and also by the interaction of FeCl_3 and steam.

LANTHANUM (vol. iii. p. 116). Bettendorff (*A.* 256, 159 [1890]) obtained the value 138.23 for the at. w.; and Brauner (*B.* 24, 1328 [1891]) the value 138.21 ($O = 16$).

Winkler (*B.* 24, 873 [1891]) obtained results, by heating La_2O_3 with Mg in H, which pointed to the existence of a hydride of La (cf. Brauner, *l.c.*).

LEAD (vol. iii. p. 122). The molecule in dilute solution in tin is probably monatomic (Heycock a. Neville, *C. J.* 57, 876 [1890]). The m.p. of lead was found by Griffiths a. Calendar (using a Pt thermometer) to be 327.69° (*C. N.* 63, 1 [1891]). Lehmann (*Z. K.* 17, 274 [1890]) says that lead separated electrolytically, by a weak current, crystallises in leaflets that are probably monosymmetric, but that the crystals are regular octahedra when separated by a strong current. Veley (*S. C. I.* 10, 206; summary of conclusions in *C. J.* 62, 410 [1892]) has examined the interaction of lead and nitric acid: an acid of intermediate concentration acts most rapidly; when HNO_3 is present the action increases. Montemartini (*G.* 23, 384, 397, 426 [1892]) found that a little NH_3 was produced, especially with dilute HNO_3Aq . Lead rapidly oxidises to PbO when heated in NO; oxidation occurs at $c. 200^\circ$ in NO_2 , with formation of a basic nitrate (Sabatier a. Senderens, *C. R.* 114, 1429; 115, 236 [1892]).

Lead, bromide of (vol. iii. p. 125). Several double compounds of PbBr_2 with alkali bromides have been described. For $\text{PbBr}_2 \cdot 2\text{AmBr}$, aq , and $2\text{PbBr}_2 \cdot \text{AmBr}$, v. Wells a. Johnston, *Am. S.* [3] 46, 25 (abstract in *C. J.* 64 [11], 523 [1893]); for $\text{PbBr}_2 \cdot \text{KBr}$, aq , and $\text{PbBr}_2 \cdot 2\text{KBr}$, aq , v. Herty, *Am.* 15, 357 (abstract in *C. J.* 66 [11], 465 [1894]); for $2\text{PbBr}_2 \cdot \text{RbBr}$ and $2(\text{PbBr}_2 \cdot 2\text{RbBr})$, aq , v. Well, *Am. S.* [3] 46, 34 (abstract in *C. J.* 66 [11], 324 [1893]); and for K_2PbBr_4 , aq , and $\text{K}_2\text{Pb}(\text{BrI})_4$, aq , v. Wells, *l.c.* p. 190 (abstract, *l.c.* p. 524).

Lead, chlorides of (vol. iii. p. 125). The statement, on p. 125 (vol. iii.), that only one chloride has been isolated is no longer true; PbCl , was prepared by Friedrich in 1893.

Lead tetrachloride (vol. iii. p. 126). PbCl_4 has been obtained by Friedrich (*B.* 26, 1434; *abstract in C. J.* 64 [11], 415 [1893]; *cf. M.* 14, 505; *abstract in C. J.* 66 [11], 16 [1894]), by passing Cl into HClAq containing PbCl_2 in suspension, adding NH_4Cl to the solution thus obtained, separating and drying the compound $\text{PbCl}_2 \cdot 2\text{NH}_4\text{Cl}$ thus formed, adding it to conc. cooled H_2SO_4 , allowing the oily drops that formed to collect at the bottom of the vessel, and shaking these drops repeatedly (and quickly) with conc. H_2SO_4 . PbCl_4 is a transparent, yellow, very refractive liquid, fuming in moist air with formation of PbCl_2 and Cl ; it is unchanged in contact with cold conc. H_2SO_4 , but when heated with the acid it decomposes explosively to PbCl_2 and Cl ; when heated with conc. H_2SO_4 in a current of Cl , some PbCl_4 passes over, but at c. 105° explosion occurs. PbCl_4 has S.G. 3.18 at 0° ; at c. -15° it solidifies to a yellowish, crystalline mass. A hydrate is formed with a little water; but addition of more water produces HClAq and PbO_2 . By adding PbCl_4 to a little cooled conc. HClAq , a crystalline compound, probably $\text{PbCl}_4 \cdot 2\text{HCl}$, is formed.

Several double salts of PbCl_4 with alkali chlorides have been isolated. Classen & Zahorski (*Zeit. f. anorg. Chemie*, 4, 100) give the formula $2\text{PbCl}_4 \cdot 5\text{AmCl}$ to the salt formed by digesting PbCl_4 with liquid Cl and fuming HClAq , and adding AmCl ; but Friedrich (*l.c.*) says the compound is $\text{PbCl}_4 \cdot 2\text{NH}_4\text{Cl}$. For compounds $\text{PbCl}_4 \cdot 2\text{MCl}$, when $\text{M} = \text{NH}_4$, Cs , K , and Rb , v. Wells (*Am. S.* [3] 46, 180; *abstract in C. J.* 64 [11], 523 [1893]); C. a. Z. (*l.c.*) describe compounds of PbCl_4 with the hydrochlorides of pyridine and quinoline (*abstract in C. J.* 64 [11], 464 [1893]).

Lead dichloride (vol. iii. p. 125). Several double compounds with alkali chlorides are described by Randall (*Am.* 15, 494 [1893]); Wells & Johnston (*Am. S.* [3] 46, 25 [1893]); and Wells (*l.c.* p. 84). The compounds are of the forms $\text{PbCl}_4 \cdot 2\text{MCl}$, $\text{PbCl}_4 \cdot 3\text{MCl} \cdot \text{aq}$, and $2\text{PbCl}_4 \cdot \text{MCl}$ (*v. abstracts in C. J.* 64 [11], 523, 524 [1893]).

Lead, fluorides of (vol. iii. p. 127). Brauner (*C. J.* 65, 393 [1894]) has prepared the compound $\text{PbF}_4 \cdot 3\text{KF} \cdot \text{HF}$ in various ways; the simplest process being to dissolve $\text{Pb}(\text{C}_2\text{H}_3\text{O}_2)_2$ (*v. Red oxide of lead, Addenda, infra*) in conc. HFAq and add KF . By acting on this salt with conc. H_2SO_4 , B. obtained evidence of the formation of lead tetrafluoride, PbF_4 , but he did not succeed in isolating the compound.

Lead, iodide of (vol. iii. p. 127). Several double compounds of PbI_2 with alkali iodides have been isolated by Wells, W. a. Johnston, and Herty (*v. References under LEAD BROMIDE*, p. 914). For the compound $\text{PbI}_2 \cdot 2\text{MgI}_2 \cdot 16\text{aq}$, v. Otto & Drewes (*Ar. Ph.* 229, 179; *abstract in C. J.* 64 [11], 984 [1893]).

Lead iodobromides and iodochlorides (vol. iii. p. 128). Miss Field (*C. J.* 68, 540 [1893]) has described the compounds $2\text{PbBr}_2 \cdot \text{PbI}_2$, $2\text{PbCl}_2 \cdot \text{PbI}_2$, and $5\text{PbCl}_2 \cdot \text{PbI}_2$.

Lead protoxide (vol. iii. p. 128). PbO is unchanged at c. 1750° (Read, *C. J.* 65, 818

[1894]). The hydrate $2\text{PbO} \cdot \text{H}_2\text{O}$ (vol. iii. p. 129) is obtained in large crystals by allowing a solution of PbO in KOH aq to cool in the air; CO_2 is absorbed, and the hydrate is deposited in colourless, tetragonal crystals, $a:b:c = 1:0.824$ (Luedeking, *Am.* 13, 120 [1891]).

Red oxide of lead (vol. iii. p. 130). Hutchinson & Pollard (*C. J.* 63, 1136 [1893]) have examined the reaction of Pb_2O_3 with glacial acetic acid, and have isolated lead tetracetate $\text{Pb}(\text{C}_2\text{H}_3\text{O}_2)_4$, melting at c. 175° , and decomposing a little above that temperature.

Note.—The formula $\text{PbO}(\text{OC}_2\text{H}_3\text{O}_2)_2$ said to be assigned by Jacquelin to the salt obtained by him (vol. iii. p. 130, col. 2, line 28 from top; and p. 131, col. 2, line 24 from bottom) should have been given as $\text{PbO}_2(\text{C}_2\text{H}_3\text{O}_2)_2$, *old notation*.

Plumbates (vol. iii. p. 132). Kassner (*Ar. Ph.* [3] 28, 109; *abstract in C. J.* 58, 561 [1893]) describes plumbates of Ba , Ca , and Sr . Regarding the dissociation of Ca plumbate, v. Le Chatelier (*C. R.* 117, 109; *abstract in C. J.* 64 [11], 524 [1893]).

Lead oxydides (vol. iii. p. 132). Göger (*M.* 13, 510; *abstract in C. J.* 62, 1892) describes the compound $\text{PbO} \cdot \text{PbI}_2$.

Lead, salts of (vol. iii. p. 132). The salt $\text{Pb}(\text{C}_2\text{H}_3\text{O}_2)_4$ (*v. supra, Red oxide of lead*) belongs to the type PbX_4 , to which form PbCl_4 also belongs.

Lead, sulphide of (vol. iii. p. 133). According to Hannay (*C. J. Proc.*, Nos. 139 and 141 [1894]), when air is passed into molten PbS , one half of the lead remains as lead, and one half is volatilised, and deposited as PbS ; H. accounts for this change by supposing the reaction to be $2\text{PbS} + \text{O}_2 = \text{Pb} + \text{PbS}_2\text{SO}_3$, the volatile PbS_2SO_3 being decomposed in the colder part of the apparatus to PbS and SO_2 .

Lead sulphobromide and sulphochloride (vol. iii. p. 133). Parmentier (*C. R.* 114, 298; *abstract in C. J.* 62, 685 [1892]) obtained the compounds $\text{PbS} \cdot \text{PbBr}_2$, and $\text{PbS} \cdot \text{PbCl}_2$, by dissolving the halides in their acids and shaking the liquids while H_2S was passed over the surfaces of the solutions.

LITHIUM (vol. iii. p. 147). Guntz (*C. R.* 117, 732 [1893]) recommends to use a mixture of equal weights of LiCl and KCl , for the electrolytic preparation of the metal; the mixture melts at 450° and the m.p. decreases as electrolysis proceeds. (For details as to size of electrodes, strength of current, &c., *v. abstract in C. J.* 66 [11], 91 [1894].) Holt & Sims, *C. J.* 65, 443 [1894], find that traces of a peroxide are formed, along with Li_2O , by burning Li in O .

Lithium, amide of, LiNH_2 . Formed by gently heating clean Li in a stream of NH_3 until violent action ceases, and then heating to c. 400° until the reaction is finished. A white, crystalline, transparent solid; melts between 380° and 400° ; decomposes in cold water slowly, giving LiOHAq and NH_3 ; decomposed by heating in air, but without taking fire (Fisherley, *C. J.* 65; 504 [1894]; *q. v.* for further reactions).

Lithium, bromide of (vol. iii. p. 150). The hydrates $\text{LiBr} \cdot \text{aq}$, where $x=1$ and 2, are described by Bogorodsky (*J. R.* 25, 316 [1893]).

Lithium, chloride of (vol. iii. p. 150). For $\text{LiCl} \cdot \text{aq}$ and $\text{LiCl} \cdot 2\text{aq}$ *v. Bogorodsky (l.c.)*. For the double compounds $\text{LiCl} \cdot \text{MCl} \cdot \text{aq}$, where

M = Cu, Co, Fe, Mn, or Ni, v. Chassevant (*C. R.* 118, 646; 115, 113; *abstracts in C. J.* 62, 118, 1275 [1892]).

Lithium, fluoride of (vol. iii. p. 150). Poulenc (*Bl.* [3] 11, 15 [1894]) obtained LiF in regular octahedra by heating the amorphous fluoride with KHF₂ and KCl and washing with water; sl. sol. water, insol. 95 p.c. alcohol; melts at c. 1000° in H₂ and partially volatilises at 1100°–1200°.

Lithium, hydroxide of (vol. iii. p. 150). For the freezing-points of aqueous solutions of LiOH v. Pickering (*C. J.* 63, 899 [1893]).

Lithium, nitride of. Ouvrard (*C. R.* 114, 120 [1892]) obtained a black solid, probably Li₃N, by heating commercial Li to dull redness in N₂.

Lithium, oxides of (vol. iii. p. 161). Almost the only product of heating Li in O is Li₂O; only traces of a peroxide are formed (Holt & Sims, *C. J.* 65, 443 [1894]).

MAGNESIUM (vol. iii. p. 157). Burton & Vorce (*Am.* 12, 219 [1890]) obtained the value 24.22 (O = 15.96) for at. w., by converting pure Mg into Mg(NO₃)₂ and this to MgO. The molecule of Mg in dilute solution in water is probably monatomic (Heycock & Neville, *C. J.* 57, 376 [1890]). Mg crystallises in holohedral hexagonal forms, *a:c* = 1:1.6202, isomorphous with Zn and Be (B. a. V., *l.c.*).

According to Montemartini (*G.* 22, 384, 397, 426 [1892]), a considerable quantity of H is given off when Mg interacts with HNO₃Aq (c. 13 p.c.); the quantity of NH₃ formed increases with concentration of the acid up to 40 p.c. HNO₃, after which it decreases. Mg burns in NO at a dull red heat (Sabatier & Senderens, *C. R.* 115, 236 [1892]). Georgis (*G.* 21, 510 [1891]) says that Mg dissolves in water saturated with CO₂; that H is given off, and crystals of MgCO₃.8aq are deposited. For the interactions of Mg and chlorides v. Seubert & Schmidt (*A.* 267, 218; *abstract in C. J.* 62, 776 [1892]). Winkler has made an extended examination of the interactions of Mg and oxides (*B.* 28, 44, 120, 772, 2642; 24, 878, 1966; *abstracts in C. J.* 58, 831, 451, 698, 1872 [1890]; 60, 801, 1155 [1891]).

Magnesium, bromide of (vol. iii. p. 159). Beketoff (*v. abstract in C. J.* 62, 762 [1892]) gives H.F. [Mg.Br⁺] = 121,700. The double salt 2MgBr₂.PbBr₂.16aq is described by Otto & Drewes (*Ar. Ph.* 229, 585; *abstract in C. J.* 62, 566 [1892]).

Magnesium, chloride of (vol. iii. p. 159). Skinner (*C. J.* 61, 341 [1892]) gives the boiling-points of solutions of MgCl₂ in water and alcohol, from c. 4.5 to c. 14.5 p.c. MgCl₂.

Magnesium, iodide of (vol. iii. p. 161). Beketoff (*l.c.*) gives H.F. [Mg.I⁺] = 84,800.

Magnesium, nitride of (vol. iii. p. 161). For description of an experiment to demonstrate the formation of Mg₃N₂ v. Merz (*B.* 24, 8,940; *abstract in C. J.* 62, 409 [1892]).

Magnesium, oxide of (vol. iii. p. 161). MgO is unchanged at c. 1750° (Read, *C. J.* 65, 313 [1894]); heated in the electric furnace, it melts with a current of 70 volts and 850 amperes (Moissan, *C. R.* 115, 1034; *cf. C. R.* 116, 1429 [1892–3]). Richards & Rogers (*P. Am. A.* 28, 300 [1898]) found that MgO, prepared by evaporating MgCO₃, or Mg, with HNO₃Aq and heat-

ing very strongly, retained c. 10 times its volume of gas, chiefly O and N.

Magnesium, silicides of (vol. iii. p. 162). Regarding the formation of compounds by heating together Mg and Si, v. Winkler (*B.* 23, 2642; *abstract in C. J.* 58, 1873 [1890]).

MANGANESE (vol. iii. p. 177). Moissan (*C. R.* 116, 849 [1893]) obtained Mn containing 4 to 5 p.c. C, by fusing MnO with charcoal (keeping MnO in excess) by means of a current of 60 volts and 300 amperes. Prelinger (*M.* 14, 353; *abstract in C. J.* 66 [11], 49 [1894]) prepared pure Mn by heating Mn amalgam (formed by electrolysis MnCl₂Aq using a cathode of Hg) in pure H₂.

Mn is described by P (*l.c.*) as a grey porous metal; unchanged in dry air; reacts slowly with cold, rapidly with warm, water; dissolves in NH₄ClAq giving off NH₃ and H; S.G. 7.4212 referred to water at 4°. Moissan (*C. R.* 116, 1429 [1893]) found that Mn volatilises readily in the electric furnace, using a current of 80 volts and 380 amperes. Montemartini (*G.* 22, 384, 397, 426 [1892]) says that the gaseous products of the interaction of Mn and HNO₃Aq are H, NH₃, N, and N₂O. Finely divided Mn reacts with CO at c. 400°, producing MnO and C (Guntz, *C. R.* 114, 115 [1892]).

Manganese, alloys of. The presence of c. 5 p.c. Mn in iron or steel scarcely affects the properties, except by slightly increasing the tenacity and malleability; a very hard tool-steel is formed with c. 1½ p.c. Mn. Alloys with iron containing from 7 to 80 p.c. Mn are extremely hard and tough.

Manganese, amalgams of (vol. iii. p. 179). Prelinger (*M.* 14, 353; *abstract in C. J.* 66 [11], 49 [1894]) prepared Mn₂Hg, by passing a current from a kathode of Hg through saturated MnCl₂Aq to an anode of C, or Pt-Ir, in a porous vessel, washing in running water, squeezing out excess of Hg, and drying in H over CaCl₂. By heating gently in a stream of pure, dry H₂, pure Mn was obtained.

Manganous chloride (vol. iii. p. 179). Chassevant (*A. Ch.* [6] 30, 5 [1893]) describes several double salts of MnCl₂; viz. MnCl₂.AmCl₂.2aq, MnCl₂.2AmCl₂.aq, and MnCl₂.LiCl₂.8aq. For the double salts M.KCl.2aq, M.CsCl.2aq; M.2XCl.2aq, X = NH₄, Cs, Rb; 2M.MgCl₂.12aq (M = MnCl₂), v. Saunders (*Am.* 14, 127; *abstract in C. J.* 62, 780 [1892]).

Manganic chlorides (vol. iii. p. 180). Regarding the composition of the chloride in the solution obtained by dissolving MnO₂ in HClAq, v. Vernon (*P. M.* [5] 31, 469), and Pickering (*P. M.* [5] 33, 284) (*abstracts in C. J.* 62, 19, 687 [1892]).

Manganese peroxide (vol. iii. p. 183). Regarding the compositions of the hydrated oxides, approximately MnO₂.2aq, prepared by different methods, v. Gorgeu (*Bl.* [3] 4, 16 [1891]). G. (*C. R.* 110, 857; *abstract in C. J.* 58, 946 [1890]) gives some details regarding the interaction of MnO₂.2aq and H₂O₂Aq. Heated in the electric furnace, MnO₂ melts, gives off O, and leaves MnO (Moissan, *C. R.* 115, 1034 [1892]). Mn₂O₃ is said to be formed by heating MnO₂ to c. 400° in NO (Sabatier & Senderens, *C. R.* 114, 1476 [1892]). McLeod (*C. J.* 65, 202 [1894]) has confirmed his former observation that Cl is

given off when MnO_2 and KClO_3 are heated together. Regarding compounds of MnO_2 with basic oxides, v. Rousseau (*C. R.* 112, 525; 114, 72; 116, 1060; *abstracts in C. J.* 60, 646 [1891]; 62, 569 [1892]; 64 [11], 416 [1893]).

Permanganates (vol. iii. p. 186). Regarding the interaction of permanganates with $\text{H}_2\text{O}_2\text{Aq}$, v. Gorgeu (*C. R.* 110, 958; *abstract in C. J.* 58, 1062 [1890]). Klobb (*Bl.* [3] 3, 508; *abstract in C. J.* 58, 947 [1890]) describes compounds of NH_3 with permanganates of Cd, Cu, Ni, and Zn.

Barium permanganate BaMn_2O_7 (the formula is wrongly printed BaMnO_4 in vol. iii. p. 186). For the preparation of this salt from KMnO_4Aq and $\text{Ba(NO}_3)_2\text{Aq}$ v. Muthmann (*B.* 26, 1016; *abstract in C. J.* 64 [11], 324 [1893]).

Calcium permanganate. The formula given on p. 186 of vol. iii. is wrong; it should be $\text{CaMn}_2\text{O}_7 \cdot 6\text{H}_2\text{O}$.

Potassium permanganate (vol. iii. p. 186). Tivoli (*G.* 19, 630 [1890]) gives the following as the reactions that occur when pure AsH_3 is passed into dilute KMnO_4Aq : (1) $2\text{KMnO}_4\text{Aq} + \text{AsH}_3 = \text{K}_2\text{HASO}_4\text{Aq} + \text{Mn}_2\text{O}_3 + \text{H}_2\text{O}$; (2) $2\text{KMnO}_4\text{Aq} + \text{AsH}_3 = \text{K}_2\text{HASO}_4\text{Aq} + 2\text{MnO}_2 + \text{H}_2\text{O}$.

Silver permanganate (vol. iii. p. 187). AgMnO_4 decomposes slowly at the ordinary temperature, rapidly at 100° , and very rapidly at 185° (Gorgeu, *C. R.* 114, 912; *abstract in C. J.* 62, 942 [1892]).

Manganous sulphide (vol. iii. p. 188). The pp. produced by adding $(\text{NH}_4)\text{HSAq}$ to an ammoniacal solution of a Mn salt, after washing in an atmosphere of H_2S and drying in CO_2 at 70° , is MnS ; S.G. $\frac{170}{17} = 3.55$. By heating to 300° – 320° , or by leaving in contact with $(\text{NH}_4)\text{HSAq}$ for some days, the reddish MnS becomes green without changing its composition; the green form of MnS is crystalline, S.G. $\frac{170}{17} = 3.63$ (Antony a. Donnini, *G.* 23 [1], 560 [1892]).

MASRIUM. In 1892 (*C. J.* 61, 491) Richmond a. Husseinoff obtained indications of the existence of an element before unknown in specimens of Egyptian fibrous alums. The supposed new element gave reactions indicating analogies with Be, Ca, and Zn; the results obtained by decomposing the oxalate by heat led to the at. w. of c. 228. The authors suggested the name *masrium*, from the Arabic name for Egypt.

MERCURAMMONIUM COMPOUNDS (vol. iii. p. 206).

Mercurio-ammonium salts $\text{NH}_4 \cdot x\text{Hg}_2\text{X}$ (vol. iii. p. 207). Barfoed's conclusion that these supposed compounds are really mixtures of mercurio-compounds and Hg is confirmed by Pesci (*G.* 21 [11], 569 [1891]). The product of the interaction of HgCl and NH_3Aq , described as *dimercurio-ammonium chloride* $\text{NH}_4\text{Hg}_2\text{Cl}$ in vol. iii. (p. 208), leaves metallic Hg when treated with ammoniacal $(\text{NH}_4)_2\text{SO}_4\text{Aq}$, according to P. When the reaction of HrCl with NH_3Aq proceeds out of the light, P. says that the change is $2\text{Hg}_2\text{Cl}_2 + 4\text{NH}_3\text{Aq} = (\text{NH}_4)_2\text{Cl} \cdot \text{NH}_4\text{Cl} + 2\text{NH}_4\text{ClAq} + 2\text{Hg}$. Similarly the reaction of NH_3Aq with Hg_2SO_4 produces a double compound of dimercurio-ammonium sulphate $((\text{NH}_4)_2\text{SO}_4 \cdot (\text{NH}_4)_2\text{SO}_4)$ and Hg; and

$(\text{NH}_4)_2\text{NO}_3 \cdot \text{NH}_4\text{NO}_3$ and Hg are formed, according to P. when HgNO_3Aq is treated with NH_3Aq .

Mercurio-ammonium salts $\text{NH}_4\text{Hg}_2\text{X}$. Regarding the conditions of formation of compounds of mercurio-ammonium chloride $\text{NH}_4\text{Hg}_2\text{Cl}$ (vol. iii. p. 208) with HgCl and $\text{NH}_4(\text{Hg}_2\text{O})\text{Cl}$, v. Balestra (*G.* 21 [11], 294; *abstract in C. J.* 62, 276 [1892]).

Dimercurio-ammonium salts $\text{NH}_4\text{Hg}_2\text{X}$ (vol. iii. p. 209). Pesci (*G.* 20, 485 [1890]) has examined the conditions of formation of various salts of this class, especially the *nitrate* $\text{NH}_4\text{Hg}_2\text{NO}_3$ and compounds of this with NH_4NO_3 . The *sulphate* $(\text{NH}_4)_2\text{SO}_4 \cdot 2\text{aq}$ was formed by saturating conc. NH_3Aq with HgSO_4 , allowing the solution to evaporate in an atmosphere of NH_3 over CaO , and collecting the first crop of crystals; various compounds of $(\text{NH}_4)_2\text{SO}_4$ with $(\text{NH}_4)_2\text{SO}_4$ are also described (v. *abstract in C. J.* 60, 268 [1891]).

MERCURY (vol. iii. p. 212). Heycock a. Neville's results (*C. J.* 57, 376 [1890]) show that some condensation from monatomic molecules perhaps occurs in dilute solutions of Hg in tin. For corrected tables of the vapour pressures of Hg for each 10° from 180° to 480° , and each 1° from 380° to 860° , v. Young (*C. J.* 59, 629 [1891]).

Jäger (*W.* 48, 209 [1893]) recommends to prepare pure Hg by converting Hg that has been distilled *in vacuo* into HgNO_3 , and electrolysis a solution of the salt, using Pt as cathode and distilled Hg as anode. Shenstone (*C. J.* 61, 452 [1892]) noticed that Hg adheres to glass when brought into contact with Cl, Br, or I. Montemartini (*G.* 22, 384, 397, 426 [1891]) finds that the amount of NO produced by the interaction of Hg and HNO_3Aq decreases as concentration of the acid increases; that NO_2 is produced with acid more conc. than 27.5 p.c. HNO_3 , HgNO_3 is formed with 25 p.c. acid, but $\text{Hg(NO}_3)_2$ with 50 to 70 p.c. acid; no NH_3 is formed with 27 and 50 p.c. acid.

Mercuric bromide (vol. iii. p. 215). HgBr_2 boils at 325° , according to Freyer a. V. Meyer (*Zeit. f. anorg. Chemie*, 2, 1 [1892]).

Mercurous chloride (vol. iii. p. 215). Harris a. V. Meyer have re-determined the V.D. of calomel at 448° and 518° ; the value obtained was 117.5. H. a. M. obtained considerable quantities of Hg and HgCl , by allowing the vapours obtained by heating calomel to c. 465° to diffuse along a glass tube; also by heating calomel at 420° for half an hour in a distillation flask at 83 mm. pressure. By heating calomel to 240° – 260° , and bringing a piece of KOH, which had been heated to c. 250° , into the vapour, they noticed that the surface of the KOH at once became covered with yellow HgO ; they also found that a piece of gold leaf held for a moment in the vapour was amalgamated (if kept for some time in the hot vapour the yellow colour was restored). H. a. M. think their results leave no doubt that the vapour obtained by heating calomel is $\text{Hg} + \text{HgCl}_2$, and that the molecular formula of calomel is Hg_2Cl_2 .

The reaction of Hg_2Cl_2 with NH_3Aq gives $(\text{NH}_4)_2\text{Cl} \cdot \text{NH}_4\text{Cl}$ and Hg, according to Pesci (v. *supra*, **MERCURIO-AMMONIUM SALTS**).

Mercuric chloride (vol. iii. p. 217). HgCl_2 boils at 307° (Freyer a. V. Meyer, *Zeit. f. anorg. Chemie*, 2, 1 [1892]). The white substance

produced by the reaction of HgCl_2Aq with a silver photographic image, or with pulverulent Ag, is HgAgCl_2 , according to Jones (*S. C. I.* 12, 983; *abstract in C. J.* 66 [11], 138 [1894]).

Mercuric cyanide; for an account of the conditions of formation and properties of the double mercury-zinc cyanide, v. Dunstan (*C. J.* 61, 666 [1897]).

Mercury, haloid compounds of (vol. iii. p. 219). Wells (*Am. S.* [3] 44, 221; *abstract in C. J.* 54 [11], 68 [1893]) describes a number of double compounds of mercury and cesium halides; the compounds belong to the forms (1) Cs_2HgX_4 , (2) Cs_2HgX_3 , (3) $\text{Cs}_2\text{Hg}_2\text{I}_4$, (4) CsHgX_3 , (5) CsHg_2X_3 , (6) CsHg_3X_3 ; $\text{X} = \text{Cl, Br or I}$; in some cases the total X atoms comprise two different halogens.

Mercury hydrosulphide; for experimental attempts to prepare a definite compound, v. Linder a. Picten (*C. J.* 61, 123 [1892]).

Mercury phosphide (vol. iii. p. 223). By heating Hg and P_2 in a sealed tube for many hours at 275°–300°, and removing Hg_2I_2 by treatment with KIAq , Granger (*C. R.* 115, 229 [1892]) obtained Hg_3P_2 in lustrous, metal-like, hexagonal crystals, appearing red by transmitted light, and giving a brown powder. The compound gives Hg and P when heated; heated in air it burns; detonates when mixed with KClO_4 and struck; burns in Cl; dissolved by *aqua regia*.

Mercurous sulphide (vol. iii. p. 224). Antony a. Sestini (*G. Z.* 24 [1], 193 [1894]) obtained a black powder by passing dry H_2S , diluted with CO_2 , over dry HgCl_2 or $\text{Hg}(\text{C}_2\text{H}_3\text{O}_2)_2$, kept at –10°; when freshly prepared the black powder was scarcely changed in dry HCl at –18°, but at a somewhat higher temperature (below 0°) Hg_2Cl_2 was quickly formed. The substance dissolved in cold K_2SAq or Na_2SAq , but when temperature rose above 0° the solution became turbid and ppd. Hg. A. a. S. think their results show that Hg_2S exists at low temperatures (*abstract in C. J.* 66 [11], 318 [1894]).

Mercury sulphochloride (vol. iii. p. 225). The compound $2\text{HgS} \cdot \text{HgCl}_2$ is formed, according to Colson (*C. R.* 115, 657 [1892]), by passing H_2S into a solution of HgCl_2 in dry benzene.

MOLYBDENUM (vol. iii. p. 421). Smith a. Maas (*A. C. J.* 15, 397 [1893]) obtained the mean value 95.85 ($\text{O} = 15.96$) for the at. w. of Mo, by heating Na_2MoO_4 in a current of dry HCl and weighing the NaCl that remained ($\text{MoO}_3 \cdot 2\text{HCl}$ and H_2O were formed and removed). Smith a. Oberholtzer (*Zeit. f. anorg. Chemie*, 5, 693 [1893]) say that a mixture of MoOCl_3 and $\text{Mo}(\text{CO})\text{Cl}_3$ is formed by heating Mo to 150°–200° in COCl_2 ; and that $\text{Mo}_2\text{S}_2\text{Cl}_4$ is produced by heating Mo to redness in S_2Cl_2 . Mo is said to ppt. Ag from AgNO_3Aq , Au from AuCl_3Aq , HgCl_2 and then Hg from HgCl_2Aq , and Cu from solutions of its salts (Smith, *Zeit. f. anorg. Chemie*, 1, 360 [1891]). Montemartini (*G. Z.* 22, 384, 397, 426 [1891]) finds that no NH_3 is formed in the interaction of Mo and HNO_3Aq with from 3 to 70 p.c. HNO_3 ; the most vigorous action occurs with acid c. 50 p.c., but the whole of the metal is not oxidised to MoO_3 , a nitrate being probably formed; the gaseous products are NO and NO_2 , the quantity of NO decreasing as the concentration of the acid increases.

Molybdenum, carbides of. By heating a mixture of MoO_3 and charcoal in the electric furnace, Moissan (*C. R.* 116, 1225 [1893]) obtained a very hard carbide, containing from 9.77 to 9.9 p.c. C; S.G. 8.6.

Molybdenum sesquioxide (vol. iii. p. 431). Heating MoO_3 in NO produces MoO_3 (Sabatier a. Senderens, *C. R.* 114, 1429 [1892]).

Molybdenum trioxide (vol. iii. p. 432). MoO_3 , partially volatilises, and is partially reduced to one of the blue oxides, at c. 1750° (Read, *C. J.* 65, 313 [1894]). According to Smith a. Oberholtzer (*Zeit. f. anorg. Chemie*, 4, 236 [1893]), the products of heating MoO_3 in HBr are (1) $\text{MoO}_3 \cdot 3\text{HBr}$, and (2) $\text{Mo}_2\text{O}_3 \cdot \text{Br}_2$; when HI is used and the temperature kept at 105°–120°, a blue oxide $\text{Mo}_2\text{O}_3 \cdot 2\text{aq}$ is formed; HF at 800°–400° forms $\text{Mo}_2\text{O}_3 \cdot \text{F}_2$ (v. *abstract in C. J.* 64 [11], 471 [1893]). Cammerer (*Chem. Zeit.* 15, 957; *abstract in C. J.* 62, 944 [1892]) says that $2\text{MoO}_3 \cdot \text{H}_2\text{O} \cdot \text{H}_2\text{O}$ is formed by boiling MoO_3 with $\text{H}_2\text{O}_2\text{Aq}$.

Molybdenum, oxybromides of (vol. iii. p. 433). Smith a. Oberholtzer (*Zeit. f. anorg. Chemie*, 4, 236 [1893]) describe $\text{Mo}_2\text{O}_3 \cdot \text{Br}_2$; square plates, colour of KMnO_4 . Formed, along with $\text{MoO}_3 \cdot 3\text{HBr}$, by heating MoO_3 in HBr.

Molybdenum, oxychlorides of (vol. iii. p. 433). For the products of the interaction of MoO_3Cl_3 and NH_3 , v. Smith a. Lehner (*Zeit. f. anorg. Chemie*, 4, 374; *abstract in C. J.* 64 [11], 529 [1893]).

Molybdenum, oxycyanide of. By dissolving MoO_3 in KCyAq , and adding a strong acid, Péchard (*C. R.* 118, 804 [1894]) obtained MoO_2Cy_2 . Easily decomposed by contact with acids; double compounds with KCy and AgCy are also described.

Molybdenum, oxyfluorides of (vol. iii. p. 433). For $\text{Mo}_2\text{O}_3 \cdot \text{F}_2$, a white, crystalline, deliquescent solid, obtained by heating MoO_3 in HF at 800°–400°, v. Smith a. Oberholtzer (*l.c.*).

Molybdenum, thiochloride of. For $\text{Mo}_2\text{S}_2\text{Cl}_4$, v. S. a. O. (*l.c.* 5, 63).

Molybdates, and derivatives thereof (vol. iii. p. 423). For compounds of molybdates of NH_3 and K with SO_2 and SeO_2 , v. Péchard (*C. R.* 116, 1441; 117, 104; *abstracts in C. J.* 64 [11], 530 [1893]).

Permolybdates. By the reaction of $\text{H}_2\text{O}_2\text{Aq}$ with $\text{K}_2\text{Mo}_2\text{O}_7\text{Aq}$, Péchard (*C. R.* 112, 720; *abstract in C. J.* 60, 988 [1891]) obtained potassium permolybdate $\text{K}_2\text{Mo}_2\text{O}_7 \cdot 4\text{aq}$; the corresponding NH_4 salt was also formed.

Arseno-molybdates (vol. iii. p. 425). For salts of this class, v. Friedheim (*Zeit. f. anorg. Chemie*, 2, 314; 6, 11, 27; *abstracts in C. J.* 64 [11], 283; 66 [11], 288 [1893–4]).

Iodomolybdates. A great many salts of the form $x\text{MoO}_3 \cdot y\text{I}_2 \cdot z\text{MO}$ are described by Blomstrand (*Zeit. f. anorg. Chemie*, 1, 10; *abstract in C. J.* 64 [11], 122 [1893]).

Phosphomolybdates (vol. iii. p. 426). Friedheim (*Zeit. f. anorg. Chemie*, 4, 275; 6, 11, 27; *abstracts in C. J.* 64 [11], 472; 66 [11], 288 [1893–4]) describes several salts of this class.

Fluoromolybdates (vol. iii. p. 425). v. Piccini (*Real. Acad. Lincei*, 7 [1], 267; *abstract in C. J.* 62, 784 [1892]), and Mauro (*l.c.*, 1892 [1], 194; *abstract in C. J.* 64 [11], 124 [1893]).

NICKEL (vol. iii. p. 498). The at. w. has been re-determined (1) by Schützenberger, by reducing oxides of Ni in H (C. R. 114, 1149 [1892]); (2) by Winkler, by estimating Cl in NiCl₂ prepared from electrolytically deposited Ni (*Zeit. f. anorg. Chemie*, 4, 10 [1893]). Schützenberger's values varied from 58.50 to 59.8; Winkler's mean value from the gravimetric determinations was 58.903, and from the volumetric determinations 58.910 (Cl = 35.37, Ag = 107.66). Krüss a. Schmidt (*Zeit. f. anorg. Chemie*, 2, 235 [1892]) insist that the substance called nickel is not an element, but Winkler (*l.c.*) controverts this statement (*v. abstracts in C. J.* 64 [11], 212, 469 [1893]). The molecule of Ni in dilute solution in tin is probably monatomic (Heycock a. Neville, C. J. 57, 376 [1890]). Schützenberger (C. R. 113, 177 [1891]) says that a volatile compound is formed by passing dry HCl over finely divided Ni heated to dull redness. Montemartini (G. 22 [1], 250; *abstract in C. J.* 62, 1278 [1892]) gives the quantities of NH₃, N₂O, N, and HNO₂ (no NO) produced by the reaction of excess of HNO₃Aq (27.5 p.c.) with Ni. Heated to 200° in NO, the oxide NiO is formed without any Ni₂O₃ (Sabatier a. Senderens, C. R. 114, 1429 [1892]). By passing NO₂, diluted with N, over reduced Ni, nitro-nickel (? Ni₂NO₂) is obtained; it resembles nitro-cobalt (q. v., p. 908) (S. a. S., *Bl.* [3] 9, 669 [1893]).

Nickel carbonyl Ni(CO)₄. (*Nickel carbonyl*, vol. iii. p. 501.) Mol. w. was confirmed by Mond a. Nasini (*Z. P. C.* 8, 150 [1891]), by finding the depression of the freezing-point of benzene. S.G. 1.35613 at 0°, 1.27132 at 36° (water at 4° = 1); S.G. at b.p. = 1.25406; molecular volume = 136.04; critical temp. = 151°. For some reactions v. Berthelot (C. R. 112, 1848; *abstract in C. J.* 60, 1427 [1890]).

Nickel, chloride of (vol. iii. p. 501). A volatile substance, decomposed by heating, is said to be formed by passing dry HCl over dry NiCl₂ at dull redness (Schützenberger, C. R. 113, 177; v. *abstract in C. J.* 60, 1429 [1890]). Chassevant (*A. Ch.* [6] 30, 5 [1893]) describes the double compounds NiCl₂.AmCl.6aq and NiCl₂.LiCl.8aq.

Nickel, fluoride of (vol. iii. p. 502). Poulenc (C. R. 114, 1426 [1892]) obtained amorphous NiF₂ by heating NiCl₂ with excess of NH₄F, and washing away NH₄Cl with boiling alcohol; by heating in HF to 1200°–1300°, the amorphous NiF₂ became crystalline, forming green prisms, S.G. 4.63, not acted on by warm HNO₃Aq, HClAq, or H₂SO₄Aq. Heated in air, NiF₂ gives NiO; heated with S it gives NiS; and with H it is reduced to Ni (for other reactions, v. *abstract in C. J.* 62, 1159 [1892]). The double salt NiF₂.KF is formed by heating NiCl₂ with KHF₄, and washing away KCl by water (P., C. R. 114, 746 [1892]).

Nickel monoxide (vol. iii. p. 502). NiO melts and forms green crystals in the electric furnace (Moissan, C. R. 115, 1034 [1892]). NiO occludes small quantities of N and O (Richards a. Rogers, P. Am. A. 28, 200 [1893]).

Nickel sesquioxide (vol. iii. p. 502). Ni₂O₃ fuses, gives up all its O, and leaves Ni at c. 1750° (Read, C. J. 65, 313 [1894]).

Nickel peroxide (vol. iii. p. 503). Campbell a. Trompidge (*J. Anal. and App. Chem.* 7, 301;

abstract in C. J. 66 [11], 238 [1894]) conclude that an oxide with more O than Ni₂O₃ can be obtained by ppg. NiSO₄Aq by Na₂CO₃Aq in presence of Br at different temperatures.

Nickel monosulphide (vol. iii. p. 503). Regarding the oxidation of this salt in air, to NiSO₄.6NiO, &c., v. P. de Clermont (C. R. 117, 229; *abstract in C. J.* 64 [11], 528 [1893]).

NIOBIUM (vol. iii. p. 505). Nb₂O₅ is not changed at c. 1750° (Read, C. J. 65, 313 [1894]). Piccini (*Zeit. f. anorg. Chemie*, 2, 21 [1892]) has prepared potassium fluocyperniobate NbO₂F₂.2KF.aq.

NITRAMIDE NO₂(NH₂). Thiele a. Lachman (B. 27, 1909 [1894]) obtained this compound by throwing NO₂.NK.CO₂K (potassium nitro-carbamate) into a mixture of ice and excess of H₂SO₄, extracting with ether, and evaporating in a stream of air. Crystallises in clear prisms, which melt at 72° with decomposition; decomposed instantly to N₂O and H₂O by alkalis, alkali carbonates, borax, or Na acetate.

NITRATES (vol. iii. p. 509). Rousseau a. Tite (C. R. 115, 174 [1892]) find that many basic nitrates are completely decomposed by heating with water at 150°–200°. Regarding the formation of basic nitrates of Cd, Ca, Ni, and Zn, v. R. a. T. (C. R. 114, 1184; h. ban (C. R. 114, 1357); and Werner (C. R. 115, 169); *abstracts in C. J.* 62, 1156, 1157, 1276 [1892]).

NITRIC ACID (vol. iii. p. 517). Regarding the colours produced by diluting red fuming HNO₃Aq v. Marchlewski (B. 24, 3271 [1891]). For revised tables showing the composition of HNO₃Aq of different concentrations v. Lunge a. Rey (S. C. I. 1891, 543). Regarding the magnetic rotations of HNO₃Aq v. Perkin (C. J. 63, 57 [1893]). Hall (Am. 13, 564) has examined the rate of production of H and O, and the effect on the concentration of the acid, by the slow and steady electrolysis of HNO₃Aq (*abstract in C. J.* 62, 680 [1892]). The interactions of HNO₃Aq with many metals have been examined by Montemartini (G. 22 [1], 250, 277, 384, 397, 426 [1891]; *abstracts in C. J.* 62, 1278, 1402 [1892]), Veley (S. C. I. 10, 206; and elsewhere), and others; the results are noted under various metals. Pickering (C. J. 63, 436 [1893]) has isolated the hydrates HNO₃.H₂O and HNO₃.3H₂O; the freezing-points of HNO₃Aq, from 1.82 to 86.19 p.c. HNO₃, are given by P.

NITROGEN (vol. iii. p. 556). S.G. of N (air = 1) = .97209; 1 litre weighs 1.25/49 g. (Rayleigh, Pr. 53, 184 [1893]). μ_D = 1.2053 at –190° (liquid N, containing 5 p.c. O) (Livinge a. Dewar, P. M. [5] 36, 328 [1893]). Absorption coefficient in alcohol, v. Henrich (Z. P. C. 9, 485 [1892]). Diffusion in water, v. Duncan a. Hoppe-Seyler (*Zeit. physiol. Chemie*, 17, 147 [1893]).

Preparation of pure nitrogen. Threlfall (P. M. [5] 35, 1 [1893]) gives minute directions for preparing pure N by passing air and NH₃ over hot Cu, and absorbing traces of O by CrCl₃Aq; exact directions for preparing the CrCl₃Aq are given, and the paper contains numerous details regarding the purifications of the reagents used in the process.

Supposed allotropic form of nitrogen. Threlfall (*l.c.*) has repeated experiments on sparking extremely pure N (v. vol. iii. p. 557); no condensation occurred down to –10° and c. 8 mm.

pressure, but when Hg is present a compound of N and Hg is formed (probably Hg_2N_2 , v. vol. iii. p. 221). Regarding the fixation of nitrogen by growing plants, v. Beyerinck, also Schloesing a. Laurent (abstracts in *C. J.* 62, 1019, 1021 [1892]).

Nitrogen, hydrides of (vol. iii. p. 559). *Hydrazic acid* N_2H_4 . For new methods of preparing N_2H_4 v. Curtius (*B. Z.* 24, 3841; 26, 1263; abstracts in *C. J.* 62, 112; 64 [11], 463 [1892-3]). Wislicenus (*B. Z.* 25, 2084 [1892]) has obtained N_2H_4 by the interaction of NH_3 and N_2O . From $\frac{1}{2}$ g. to $\frac{1}{2}$ g. Na is heated in a stream of NH_3 , until all is converted into NaNH_2 ; a current of dry N_2O is then passed over the NaNH_2 at 150° – 250° as long as NH_3 is given off ($2\text{NaNH}_2 + \text{N}_2\text{O} = \text{NaN}_3 + \text{NaOH} + \text{NH}_3$). By dissolving the product in water, filtering, decomposing by dilute H_2CO_3 aq. and distilling, N_2H_4 aq. is obtained.

The following salts are described by Curtius (*B. Z.* 24, 3841; abstract in *C. J.* 62, 112 [1892]): $(\text{NH}_4)_2\text{N}_2$, $\text{Pb}(\text{N}_2)_2$, HgN_2 , NaN_2 .

Nitrogen, iodides of (vol. iii. p. 560). Diiodamine, NHI_2 , is the product of adding excess of NH_3 aq. to a conc. solution of I in conc. KI aq.; by suspending NHI_2 in water, and adding an ammoniacal solution of AgNO_3 or Ag_2O , a black compound NAgI_2 is obtained which explodes when dry (Szuhay, *B. Z.* 26, 1933; abstract in *C. J.* 64 [11], 568 [1893]; cf. Selivanoff, *B. Z.* 27, 1012; abstract in *C. J.* 66 [11], 812 [1894]).

Nitrous oxide (vol. iii. p. 561). Ramsay a. Shields (*C. J.* 63, 883 [1893]) give the m.p. of N_2O as -102.8° , and the b.p. as -89.8° . Villard (*C. R.* 118, 1096 [1894]) gives the following data for the S.G. of liquid N_2O : $\cdot 9105$ at 0° , $\cdot 885$ at 5° , $\cdot 856$ at 10° , $\cdot 804$ at 17.5° , $\cdot 720$ at 26.5° , $\cdot 640$ at 32.9° , $\cdot 605$ at 34.9° , $\cdot 572$ at 36.3° . Liveing a. Dewar (*P. M.* [5] 34, 205 [1892]) give

$$\frac{\mu_D - 1}{d} = -2634, \text{ and } \frac{\mu^2 - 1}{(\mu^2 + 2)d} = -163 \text{ at } -90^\circ.$$

Smith (*S. C. J.* 11, 867; 12, 10 [1893]) says that a regular stream of N_2O is obtained by heating to 240° – 250° a mixture of 1 pt. dry NaNO_3 with c. $1\frac{1}{2}$ pt. dry $(\text{NH}_4)_2\text{SO}_4$. By passing N_2O , mixed with a little H, over Pd black, the H is entirely converted to H_2O , with formation of N (Montemartini, *Real. Acad. Lincei*, 7 [11], 219 [1892]).

Nitric oxide (vol. iii. p. 562). Very pure NO is obtained, according to Emich (*M.* 13, 73 [1892]), by the interaction of copper and a mixture of H_2SO_4 and HNO_3 aq. Emich (*l.c.*, p. 78) finds that NO is completely decomposed to N and O by passing over nets of Pt or Pd wire kept very hot by an electric current. Emich (*l.c.*, p. 86) says that NO and O unite after being dried by long contact with P_2O_5 ; but Baker (*C. J.* 65, 611 [1894]) finds that dry NO and dry O do not combine at the ordinary temperature. Regarding the reactions between NO and metals and metallic oxides, v. Sabatier a. Senderens (*C. R.* 114, 1429; 1476; abstracts in *C. J.* 62, 1151, 1271 [1892]; results are noted under the different metals and oxides in *Addenda*).

Nitrogen dioxide (vol. iii. p. 565). For the reactions of NO_2 with various metals and oxides v. S. a. S. (*C. R.* 115, 286; abstract in *C. J.* 63, 1390 [1892]; results are noted under the different metals and oxides in *Addenda*).

Nitrogen tetroxide (vol. iii. p. 565). For preparation of N_2O_4 , v. Cundall (*C. J.* 59, 1076 [1891]). C. (*l.c.*) has measured the dissociation of liquid N_2O_4 in CHCl_3 up to c. 25° ; Ostwald (*C. J.* 61, 242 [1892]) shows that the dissociation follows van't Hoff's law for dilute solutions.

Nitrous acid (vol. iii. p. 567). Regarding the formation of HNO_2 in solution in HNO_3 , v. Veley (*Pr.* 52, 27; abstract in *C. J.* 64 [11], 413 [1893]).

Hyponitrous acid (vol. iii. p. 568). Tanatar (*J. R.* 25, 342; abstract in *C. J.* 66 [11], 186 [1894]) prepared $\text{Ag}_2\text{N}_2\text{O}$ by adding CaO to fairly conc. KNO_3 aq. in the ratio $\text{CaO}:\text{KNO}_3$, then an equivalent of solid $\text{NH}_4\text{OH} \cdot \text{HCl}$, heating to 50° , letting stand for a few days at the ordinary temperature, filtering, acidifying with acetic acid, ppg. by AgNO_3 aq., dissolving $\text{Ag}_2\text{N}_2\text{O}$ in HNO_3 aq. (which leaves AgCl), and ppg. again by Na acetate.

OSMIUM (vol. iii. p. 641). Os fuses readily in the electric arc in a carbon capsule; when fused it has a crystalline fracture, and scratches quartz, but is scratched by topaz (Joly a. Vézès, *C. R.* 116, 577 [1893]).

Osmic acid (vol. iii. p. 646). Morlet a. Wischin (*Zeit. f. anorg. Chemie*, 3, 153; abstract in *C. J.* 64 [11], 380 [1893]) say that the black powder obtained by the interaction of acids and K_2OsO_4 aq. (vol. iii. p. 645), when dried over P_2O_5 in *vacuo* till it ceases to lose weight, is osmic acid H_2OsO_4 . M. a. W. describe the compound as a sooty-black powder, smelling of OsO_4 in moist air, but unchanged under water containing alcohol. By passing H_2S over H_2OsO_4 , a violent reaction occurs, and $\text{OsO}_3\text{S}_2 \cdot \text{H}_2\text{O}$ is formed. Heated with conc. HCl aq. for many hours with a little alcohol, and evaporated, Os_2Cl_7 7aq was obtained; an alcoholic solution of this substance with KCl aq. gave K_2OsCl_6 , and the filtrate yielded $\text{OsCl}_4 \cdot 3\text{aq}$; the substance Os_2Cl_7 is therefore supposed by M. a. W. to be a mixture of OsCl_4 and OsCl_2 . By heating H_2OsO_4 with HI aq., violet-black crystals, probably OsI_4 , were obtained. No action occurs when Os is heated with I, or with Br.

Potassium osmiate (vol. iii. p. 645). Joly (*C. R.* 112, 1442 [1891]) prepares this salt by dissolving 100 pts. OsO_4 in a solution of 100 pts. KOH in 50 pts. H_2O , keeping the solution at c. 40° , and adding 40 c.c. NH_3 aq.; after a time the brown liquid becomes colourless, and a yellow crystalline pp. is formed. J. gives the formula KNOsO_4 to this salt. Heated in *vacuo* it is rapidly decomposed above 200° , and at 440° almost all the N is given off, the solid products being K_2OsO_4 , OsO_3 , and KOsO_4 (v. abstract in *C. J.* 60, 1433 [1891]).

OXIDES (vol. iii. p. 658). Regarding the connections between the stability of oxides when heated and the periodic classification of the elements, v. Bailey (*C. J.* 65, 106, 321 [1894]).

OXYGEN (vol. iii. p. 708). *Atomic weight of oxygen* (vol. iii. p. 705). Dittmar a. Henderson (*C. N.* 67, 127, 139, 151, 164; abstract in *C. J.* 64 [11], 410 [1893]) from careful determinations made by passing H over hot CuO , and weighing the water and Cu produced, adopt the value 15.87 for the at. w. of O. By measurements of the combining volumes of O and H, combi-

ning the results with Rayleigh's determination of the S.G. of O, Scott (*T.* 184, 548 [1898]) got the value 15.862. The following values summarise the most recent determinations (v. D. a. H., *l.c.*), Oooke a. Richards, 15.868; Noyes, 15.886; Rayleigh (*Pr.* 45, 425 [1890]), 15.89; Keiser, 15.949; Leduc (*C. R.* 116, 1248 [1893]), 15.88; D. a. H., 15.87; Scott, 15.862. The value adopted in this *Dictionary*, 15.96, is almost certainly too high; the mean of the values obtained by C. a. R., N., R., D. a. H., and S., is 15.875.

The ratio of the combining volumes of O and H was determined by Scott (*l.c.*) to be 2.00245:1 (v. WATER, this vol. p. 861). S.G. of O referred to H = 15.882 (Rayleigh, *Pr.* 50, 448 [1892]). For an examination of the whole of the spectrum of O, v. Eisig (*W.* 51, 747: *abstract in C. J.* 66 [11], 265 [1894]). Liveing a. Dewar (*P. M.* [5] 34, 205 [1892]) determined $\frac{\mu_D - 1}{d}$ to be .1889, and

$\frac{\mu^2 - 1}{(\mu^2 + 2)d}$ to be .1265, at -182° (cf. Olszewski a. Witkowski; *abstract in C. J.* 64 [11], 358 [1893]). For diffusion of O in water, v. Duncan a. Koppe-Seyler (*Zeit. physiol. Chemie*, 17, 147 [1892]).

Regarding the division of O between H and Cl when mixtures of these gases are exploded, v. Harker (*Z. P. C.* 9, 673 [1892]). Dry O does not combine with dry NO at the ordinary temperature (Baker, *C. J.* 65, 611 [1894]); nor with dry K or Na, even when these metals are distilled in the gas (Holt a. Sims, *C. J.* 65, 440 [1894]).

OZONE (vol. iii. p. 788). Regarding the conditions of ozonification of oxygen, v. Shenstone a. Priest (*C. J.* 63, 938 [1893]). Baker (*C. J.* 65, 611 [1894]) confirms the observation of Shenstone a. Cundall (*C. J.* 81, 610 [1887]) that dry O is ozonised as rapidly as moderately dry O.

PALLADIUM (vol. iii. p. 792). The at. w. of Pd has been re-determined (1) by Bailey a. Lamb (*C. J.* 61, 745 [1892]), by analyses of $\text{Pd}(\text{NH}_4\text{Cl})_2$; (2) by Keller a. Smith (*Am.* 14, 428 [1892]), by ppg. Pd electrolytically from a solution of $\text{Pd}(\text{NH}_4\text{Cl})_2$ in NH_4Aq ; (3) by Joly a. Leidié (*C. R.* 116, 146 [1893]), by electrolysing K_2PdCl_4 in HClAq ; (4) by Keiser a. Breed (*Am.* 16, 20 [1894]), by determining the ratio of Pd to Cl in $\text{Pd}(\text{NH}_4\text{Cl})_2$. B. a. L. obtained the value 105.459; K. a. S. the value 106.35; J. a. L. the value 105.665; and K. a. B. the value 106.27 ($\text{Cl} = 35.37$; $\text{Ag} = 107.66$; $\text{N} = 14.01$; $\text{O} = 15.96$). The molecule of Pd in dilute solution in tin is probably monatomic (Heycock a. Neville, *C. J.* 57, 376 [1890]). Regarding the preparation of pure Pd, v. the memoirs referred to *supra*. Pd absorbs O at 450° , forming Pd_2O (Neumann, *M.* 13, 40 [1892]), but when Pd sponge is heated in dry O till the weight is constant PdO is formed (Wilm, *B.* 25, 220 [1892]). Heated to 200° in NO, Pd sponge that has been saturated with H becomes incandescent and the NO is completely changed to H_2O and NH_3 , but oxidation of the Pd does not occur (Sabatier a. Senderens (*C. R.* 114, 4429 [1892])). Regarding *palladium sulphides*, v. Petrenko-Kritschenko (*Zeit. f. anorg. Chemie*, 4, 247; *abstract in C. J.* 64 [11], 475 [1893]). *Phosphopalladous compounds*, PdCl_2PCL , and

$\text{PdCl}_2\text{P}(\text{OH})_3$, are described by Fink (*C. R.* 115, 176; *abstract in C. J.* 62, 1285 [1892]). Vèzes (*C. R.* 115, 111) describes *potassium palladous-chloronitrite* $\text{K}_2\text{Pd}(\text{NO}_2)_2\text{Cl}_2$ (*abstract in C. J.* 62, 1284 [1892]).

PHOSPHATES (vol. iv. p. 106). Rossel a. Frank (*B.* 27, 52) say that P is obtained by heating NaPO_3 , or any phosphate of Ca or Mg, with Al in a current of H.

Dipotassium-hydrogen orthophosphate (vol. iv. p. 111). According to Standenmaier (*Zeit. f. anorg. Chemie*, 5, 388 [1893]), K_2HPO_4 cannot be isolated. S. (*l.c.*) describes *acid salts*, $\text{K}_2\text{H}_2(\text{PO}_4)_3$, aq, $\text{K}_2\text{H}_3(\text{PO}_4)_4$, 2aq, and $\text{KH}_2(\text{PO}_4)_3$.

Thorium orthophosphates (vol. iv. p. 112). Volck (*Zeit. f. anorg. Chemie*, 6, 161 [1894]) obtained $\text{Th}(\text{HPO}_4)_2$, aq by adding dilute H_3PO_4 aq to ThCl_4Aq .

Sodium pyrophosphate (vol. iv. p. 114). For a study of the reaction of HClAq with $\text{Na}_2\text{P}_2\text{O}_7$, v. Watson (*S. C. I.* 11, 224; *abstract in C. J.* 64 [11], 272 [1893]).

ORTHOPHOSPHORIC ACID (vol. iv. p. 125). According to Watson (*C. N.* 68, 199 [1893]) H_3PO_4 is changed completely to $\text{H}_4\text{P}_2\text{O}_7$ at 255° – 260° , and HP^3 begins to form at 290° – 300° .

PHOSPHORUS (vol. iv. p. 126). Regarding the action of light and heat on *ordinary phosphorus*, v. Retgers (*Z. P. C.* 5, 211; *abstract in C. J.* 66 [11], [1894]).

Phosphorus hydride (vol. iv. p. 136). PH_3 and O react at a low pressure to form H_2PO_3 ($2\text{PH}_3 + 3\text{O}_2 = 2\text{H}_2\text{PO}_3$); when the gases are allowed to diffuse with one another at less than 50 mm. pressure, the reaction is $\text{PH}_3 + \text{O} = \text{H}_2 + \text{HPO}_2$; slow oxidation at greater pressures proceeds approximately according to the equation $4\text{PH}_3 + 5\text{O}_2 = 2\text{HPO}_3 + 2\text{H}_2\text{PO}_3 + 2\text{H}_2$ (H. J. van de Stadt, *Z. P. C.* 12, 322 [1893]). According to van de S., explosion occurs at a certain low pressure, and this pressure depends much on the amount of moisture present, the moisture preventing and retarding the explosion. Kovij (*Z. P. C.* 12, 155 [1893]) has examined the rate of decomposition of PH_3 by heat. For the reaction of PH_3 with AgNO_3Aq v. Vitali (*abstract in C. J.* 64 [11], 206 [1893]).

Phosphoric oxide (vol. iv. p. 141). For details regarding the preparation of pure P_2O_5 , and for methods of detecting traces of P in P_2O_5 , v. Threlfall (*P. M.* [5] 35, 14 [1893]).

Phosphorus suboxide (vol. iv. p. 139). Blitz (*B.* 27, 1257 [1894]) thinks that P_4O is formed by the interaction of P_2O_5 and NH_3 .

Phosphorus sulphides (vol. iv. p. 145). Helff (*Z. P. C.* 12, 196 [1893]) confirms the statement that there are no definite compounds P_4S and P_2S_3 ; by heating together red P and S, he obtained P_4S_3 , P_2S_5 , P_4S_7 , and P_2S_9 .

Phosphorus sulpholodide of. Ouvrard (*C. R.* 115, 1301; *abstract in C. J.* 64 [11], 164 [1893]) obtained $\text{P}_2\text{S}_4\text{I}$ by heating PI_3 in H_2S at 110° – 120° ; also by evaporating a solution of the three elements in the proper proportion i. CS_2 and heating the residue to 120° in an inert gas; also by dissolving I in a solution of P_2S_3 in CS_2 . The compound crystallises from CS_2 in golden-yellow prisms; it is unchanged in dry air, but slowly decomposed in moist air, giving off H_2S a. sol. CHCl_3 , C_2H_5 , EtOH , or Et_2O ; burns at c. 300°C giving P_2O_5 , SO_2 , and I; at c. 300° *in vacuo* it

separates into I and P_2S_5 ; decomposed by hot water, and explosively by fuming HNO_3 .

Potassium hypophosphates (vol. iv. p. 153). Bansa (*Zeit. f. anorg. Chemie*, 6, 128 [1894]) describes many double salts of $K_2H_2P_2O_6$ with $MH_2P_2O_6$, where $M = Cd, Co, Cu, Mn, Ni, \text{ or } Zn$; also double salts $MX_2P_2O_6$, where $M = Co \text{ or } Ni$. The double salt $K_2Na_2P_2O_6 \cdot 2aq$ is also described (abstract in *C. J.* 66 [11], 279 [1894]).

Thallium hypophosphates. Joly (*C. R.* 118, 649 [1894]) obtained the normal salt $Tl_2P_2O_6$, and the acid salt $Tl_2H_2P_2O_6$ (abstract in *C. J.* 66 [11], 282 [1894]).

PLATINATES (vol. iv. p. 281).

Sodium thioplatinates. Schneider has obtained the salts Na_2PtS_2 and $Na_2S \cdot PtS_2 \cdot 2PtS_2$ (*J. pr.* [2] 48, 411 [1894]).

Platino-oxalates (vol. iv. p. 285). Regarding the constitutional formulæ of the K salts, v. Werner (*Zeit. f. anorg. Chemie*, 8, 267), and Söderbaum (*ibid.* 6, 45 [1894]).

PLATINUM-AMMONIUM COMPOUNDS (vol. iv. p. 292). Petersen (*Z. P. C.* 10, 580 [1892]) finds, from cryoscopic determinations, that most of the formulæ generally used for these compounds are molecular. For a discussion of the constitutions of several classes of these compounds, and for measurements of the electrical conductivities of aqueous solutions of some of them, v. Werner a. Miotati (*Z. P. C.* 12, 85 [1893]).

POTASSIUM (vol. iv. p. 297). Holt a. Sims (*C. J.* 65, 432 [1894]) found that K became soft at 54.5° , and remained soft to 60.5° , whereat it became brittle; complete melting occurred at 62.5° . H. a. S. say that dry K may be distilled in dry O without the formation of any compound of the two elements. They found the products of the oxidation of K to be K_2O_2 , K_2O_3 , and finally K_2O (v. *Oxides, infra*). Mixtures of KNO_2 and KNO_3 were formed by oxidising K in NO and in the red oxides of N.

Potassiumamide (vol. iv. p. 299). Titherley (*C. J.* 65, 504 [1894]) says that KNH_2 is white and wax-like, melting at 270° – 272° . It may be distilled without change in H at 400° – 500° . T. says that KNH_2 is not decomposed by heating at c. 400° in a silver boat; if a glass vessel is used, NH_3 is given off with some N and H, and K silicate is formed; a small amount of decomposition occurs in a silver boat at c. 500° , and at a full red heat the amide distils with partial splitting up into its elements. For other reactions of KNH_2 , v. T. (*l.c.*).

Potassiummonium (vol. iv. p. 299). Joannis (*C. R.* 118, 718 [1894]) finds that there is no reaction between N and $N_2H_4K_2$; he says that N_2O produces KNH_2 , NH_3 , KOH, and N. For the action of O, v. J. (*C. R.* 116, 1870; abstract in *C. J.* 64 [11], 462 [1893]).

Potassium bromide (vol. iv. p. 299). The melting-point is given as 715° by V. Meyer a. Riddle (*B. 26*, 2448 [1893]).

Potassium chloride (vol. iv. p. 800). Melts at 766° , according to M. a. R. (*l.c.*).

Potassium hydroxide (vol. iv. p. 302). Melts at 1045° (M. a. R., *l.c.*).

Potassium iodide (vol. iv. p. 303). Melts at 623° (M. a. R., *l.c.*). Regarding the interaction of $KIAq$ and $FeCl_2Aq$, v. FERRO CHLORIDE, *Addenda*, p. 913.

Potassium tri-iodide (vol. iv. p. 304). Jakovkin (*Z. P. C.* 13, 539 [1894]) has made an examination of the dissociation of KI_3 in aqueous solution to $KIAq$ and IAq (abstract in *C. J.* 66 [11], 271 [1894]).

Potassium nitride (vol. iv. p. 304). The experiments of Titherley (*C. J.* 65, 512 [1894]) show that K_3N does not exist.

Potassium oxides (vol. iv. p. 304). Holt a. Sims (*C. J.* 65, 432 [1894]) failed to obtain the monoxide K_2O by any of the methods said to give this compound, but they say that when K_2O is kept at a red heat it loses O and gives a substance the composition of which approaches that of K_2O . By heating K in a fairly dry mixture of O and N, oxidation proceeded until K_2O was formed (dry O is without action on K); when kept in water-vapour K_2O gave off O, and formed K_2O_2 ; and by heating K in N_2O , H. a. S. obtained K_2O_3 , which on exposure to air became K_2O .

RUBIDIUM.

Rubidium haloid compounds (vol. iv. p. 413). Wheeler (*Am. S.* [3] 46, 88 [1893]) has prepared double compounds of the forms $8RbX \cdot AsX_3$ and $RbX \cdot As_2O_3$; and (*l.c.* p. 269) various compounds of RbX with SbX_3 . For physical properties of various salts of Rb, v. Erdmann, *Ar. Ph.* 232, 3 (abstract in *C. J.* 66 [11], 351 [1894]).

SELENATES (vol. iv. p. 433). Basic salts of Co and Cu are described by Bogdan (*Bl.* [3] 9, 584; abstract in *C. J.* 66 [11], 16 [1894]); the compositions given are $4CoO \cdot 3SeO_3 \cdot aq$ and $3CuO \cdot 2SeO_3 \cdot 4aq$.

SILICON CHLORIDES (vol. iv. p. 453). In B. 27, 1948 [1894] Gattermann a. Weinlig detail the best conditions for preparing $SiCl_4$, $SiHCl_3$, and Si_2Cl_6 , from crude Si obtained by the interaction of SiO_2 and Mg powder (v. vol. iv. p. 455). Si_2Cl_6 melts at -1° ; with NH_3Aq it gives off H and forms $SiO_2 \cdot xH_2O$ (G. a. W., *l.c.*).

Silicon octochloride Si_2Cl_8 . Mol. w. 866.9. V.D. 187.7. Obtained by G. a. W. (*l.c.*) by fractionating crude Si chlorides; boils from 210° to 215° ; does not solidify at -12° .

SILVER (vol. iv. p. 464). The molecule of Ag in dilute solution in tin is probably monatomic (Heycock a. Neville, *C. J.* 57, 376 [1890]). According to Lüttke (*W.* 50, 678; abstract in *C. J.* 66 [11], 92 [1894]), thin deposits of Ag on glass, mica, &c., are allotropic forms of the metal. Regarding alloys of Ag with cadmium, v. Heycock a. Neville (*C. J.* 65, 65 [1894]); v. also Mylius a. Fromm (*B. 27*, 630 [1894]).

Silver chloride (vol. iv. p. 468). By the action of $HgCl_2Aq$ on pulverulent silver, Jones (*S. C. I.* 12, 983; abstract in *C. J.* 66 [11], 138 [1894]) obtained the compound $AgHgCl_2$.

SODIUM (vol. iv. p. 473). The molecule of sodium in dilute solution in tin is probably monatomic (Heycock a. Neville, *C. J.* 57, 376 [1890]). Holt a. Sims (*C. J.* 65, 440 [1894]) found that dry sodium may be distilled unchanged in dry O; in ordinary O the products are Na_2O and Na_2O_2 . Heating to 180° – 200° in a limited volume of N_2O forms Na_2O ; heating in NO or the red oxides of N produces a mixture of $NaNO_2$ and $NaNO_3$ (H. a. S., *l.c.*).

Sodium amide (vol. iv. p. 475). Titherley (*C. J.* 65, 504 [1894]) describes NaNH_2 as a white, transparent solid, with a crystalline structure; softens at 149° , and is completely melted at 155° to a colourless liquid. NaNH_2 is obtained in transparent, crystalline needles by heating Na in NH_3 at c. 400° , allowing the product to sublime through a narrow tube, and again subliming by warming gently. NaNH_2 decomposes at a red heat into Na, N, and H. It does not give NaN_3 , as generally stated (T., l.c.); no decomposition occurs at 300° – 400° .

Sodium bromide (vol. iv. p. 476). Panfloff (*J. R.* 25, 272 [1893]) obtained NaBr. 5aq by exposing conc. NaBrAq out of doors in winter in Russia; decomposed at -25° to the dihydrate and water.

Sodium iodide (vol. iv. p. 481). NaI. 5aq separates from a solution of 100 g. NaI in 50 c.c. water at -14° ; at -10° it gives NaI. 2aq and water (P., l.c.).

Sodium nitride (vol. iv. p. 482). NaN_3 is not formed by the interaction of Na or Na_2O and NH_3 , or Na and N, according to Titherley (*C. J.* 65, 507; cf. *Sodium amide*, *supra*).

Sodium monoxide (vol. iv. p. 482). Na_2O is formed by heating Na in a limited volume of O at a temperature below 180° ; also by heating Na in a limited volume of N_2O at 180° – 200° (Holt a. Sims, *C. J.* 65, 442 [1894]). Heated in excess of O, the peroxide Na_2O_2 is formed. H. a. S. say Na_2O is greyish white. NH_3 reacts with gently-heated Na_2O to form NaNH_2 and H_2O (Titherley, *C. J.* 65, 510).

Sodium dioxide (vol. iv. p. 482). Na_2O_2 does not combine with O when heated therein (H. a. S., l.c.). Regarding the interaction of Na_2O_2 and an alcoholic solution of HCl, v. Tafel (*B.* 27, 816 [1894]). For reactions of Na_2O_2 , v. Poleck, *B.* 27, 1051 (abstract in *C. J.* 66 [11], 816).

STRONTIUM. For *Strontium carbide*, v. Moissan, *C. R.* 118, 683 (abstract in *C. J.* 66 [11], 814 [1894]).

SULPHATES (vol. iv. p. 567).

Chromium sulphates (vol. iv. p. 570). *Double salts* of $\text{Cr}_2(\text{SO}_4)_3$ and $(\text{NH}_4)_2\text{SO}_4$ are described by Klobb (*Bl.* [8] 9, 668; abstract in *C. J.* 66 [11], 95 [1894]).

Vanadium sulphates (v. this vol. pp. 847, 848, 850).

OXY-IMIDO SULPHONATES (vol. iv. p. 602). Divers a. Haga have published a lengthy communication on these salts in *C. J.* 65, 523 [1894].

SULPHUR (vol. iv. p. 606). For measurements of the viscosity of molten S at different temperatures, v. Brunhes a. Dussy, *C. R.* 118, 1045 (abstract in *C. J.* 66 [11], 343 [1894]).

THALLIUM (vol. iv. p. 674). The molecule of Tl in dilute solution in tin is probably monatomic (Heycock a. Neville, *C. J.* 54, 376 [1890]).

Thallium tri-iodide TlI_3 . Wells a. Penfield (*Zeit. f. anorg. Chemie*, 6, 812; abstract in *C. J.* 66 [11], 816 [1894]) obtained this compound, in rhombic crystals, $a:b:c = 6828:1:1.1217$, by digesting TlI and I with alcohol and evaporating over H_2SO_4 .
